LIST OF ILLUSTRATIONS IN VOLUME LVIII.

	PAGE		PAGE
Treatment of Anorectal Fistula. Seven Illustrations.....	3-7	Pott's Disease. Seven Diagrams.	490-493
Improved Aspirator and Injector.....	16	Œdematous Nasal Polypt. Seven Microphotographs..	521-525
Deglutible Electrode.....	30	Study of Clubhand. Two Illustrations.....	530, 531
Double Talipes Varo-equinus. Two Illustrations.....	74	Enormous Cerebral Tumor.....	538
Gas or Oil Stove.....	92	Vaginal Speculum.....	552
Apparatus for Steam Bath.....	92	Bandage after Thiersch's Transplantation of Skin. Three Illustrations.....	569, 570
Cases in Intestinal Surgery. Five Illustrations.....	94, 95	Apparatus for Sterilizing Eye Instruments.....	580
Improved "Grattan" Osteoclast.....	106	Eye Shield.....	581
Multiple Powder Blower.....	106	Ether Inhaler.....	581
Nasal Polypus. Three Illustrations.....	157, 158	Sphygmographic Tracings.....	588
Sphygmographic Tracing.....	225	Eye Forceps.....	596
Cannulated Surgical Needle.....	277	Eye Scissors.....	596
Charles A. L. Reed. Portrait.....	Facing 281	Blunt Hook.....	596
Malarial Fever in Infants. Three Microphotographs..	317, 318	Lance Probe.....	597
Tenorrhaphy. Four Illustrations.....	340	Tendon Crotchet.....	597
Irrigating tube.....	362	Fixation Forceps.....	597
Clinical Study of Pertussis. One Diagram, Nine Sphygmographic tracings.....	375-377	Apparatus for Osteitis of the Knee. Four Illustrations.	599, 600
Hand Ophthalmometer and Retinoscope combined.....	379	Apparatus for extracting Contents of the Stomach.....	601
Athetosis. Four Illustrations.....	395, 396	Uterine Tenaculum.....	617
Tenorrhaphy. Two Illustrations.....	397, 398	Traction Forceps.....	617
Gastro-intestinal Disease. Chart.....	457	Examination of the Uterus. Two Diagrams.....	617, 618
Recumbency in Pott's Disease. Four Diagrams.....	461	Spore of Chloronyxum Ohlmacheri.....	661
Head Sling. Two Illustrations.....	462	Relation of Heart and Lungs to Anterior Chest Wall. Four Illustrations.....	687, 688
Pelvic Belt.....	462	Aseptic Nasal Speculum.....	712
Surgical Cot. Two Illustrations.....	463	Appendicitis. Ten Illustrations.....	777-784
Surgical Cot with Wheels. Two Illustrations.....	464, 465	Spina Bifida.....	793
Adenotome.....	486		

Original Communications.

THE TREATMENT OF ANORECTAL FISTULA.*

By JAMES P. TUTTLE, M.D.,

ADJUNCT PROFESSOR OF SURGERY
AND LECTURER ON DISEASES OF THE RECTUM AND ANUS
AT THE NEW YORK POLYCLINIC.

WHILE the professional mind is so riveted upon the major operations of rectal surgery, one scarcely dares to venture before the public in an article upon so commonplace a subject as that of fistula; but those who have followed the course of post-graduate teaching have noticed in the past few years a rapidly growing interest in the subject of "diseases of the rectum"; they recognize its trend toward the position of an established specialty, and will appreciate the need of closer and renewed study of their various forms. Outside of the purely surgical, the treatment of these disorders has for a long time been largely in the hands of quacks and advertising specialists. Knowledge of or the time and patience necessary for the local and proper treatment of diseases of the rectum and anus has been so wanting with the general profession that people suffering from the minor ailments have been in self-defense driven to those outside of the pale of regular practitioners. The impression has become fixed among the laity that cutting was the only means of treatment known to or at least practiced by regular physicians in these diseases, and, dreading the knife, they have borne their inconveniences with great detriment to health and usefulness, or sought the assistance of some one advertising to cure them without operation.

The occasional (!) evil results of too much or unwise surgery about the rectum have been multiplied many fold in the minds of the public by these advertisers, and sufferers prefer to bear the aches and pains they have rather "than fly to those they know not of." One may say, however, that intelligent people will see the fallacies of these vain pretensions; but in answer we must say they are not wholly untrue, for many disorders of the rectum and anus can be relieved, if not cured, without operative procedures. And again, the public is not intelligent as a whole; they are in the large majority ignorant and confiding, especially upon subjects concerning health and disease. The medical literature which comes into their hands is largely of the quack circular or patent medicine order; with them there are not "doctors and doctors," but, with their inherited and educated reverence for the profession, they blindly trust whatever is written over the signature of "Dr."

On no other subject, perhaps, has this deception of the public been so great as on that of fistula. Incontinence, stricture, hæmorrhage, shock, blood poisoning, etc., resulting from operations for fistula, have been paraded as "Gorgons" by irregular practitioners until many believe them to be the rule rather than the exception. "Piles and fistula cured without cutting" has been a veritable gold

mine for these advertisers. Their pretensions to the possession of some secret knowledge or formula are in a measure borne out in the minds of the public by the cure of a certain number of cases which regular physicians had said were incurable unless cut, and many well-informed people are thus led to their offices for treatment.

I have in mind at present one minister, one lawyer, and two prominent business men who have all been under the care of irregular practitioners because the regular ones had failed to cure them or had told them that they could do nothing without operation. I yield to no one in maintaining a positive and consistent stand for radical treatment, but I do not believe in routine practice, and where other methods offer equal prospects of a cure I believe that they should at least be tried before resorting to the free use of the knife, especially where that use is attended with dangers of unfortunate secondary results. Of 337 cases of fistula operated on in the hospitals of New York, Boston, and Cincinnati, only 162—barely forty-eight per cent.—are even claimed as cures. Certainly we should obtain better results than this, and in private practice no doubt do so.

But is there only one cure for fistula which rectal specialists and surgeons are justified in using, and that the knife? Or can this trouble be cured by other means after the careful classification and selection of cases? I do not hesitate to say that in almost every case of anorectal fistula a certain amount of cutting is necessary upon the external surface, to drain the fistulous tract or straighten it out, so that it can be accurately followed with the probe or applicator to its highest point or opening into the intestine; but here, upon the surface, the necessary cutting ceases in the majority of cases, and the much-dreaded anæsthetic is rarely indispensable. Cocaine suffices for the prevention of pain in the treatment of a large majority of fistulæ, and many patients submit to operation under it who would rather carry their fistula to the grave than take chloroform or ether. I speak whereof I know when I say that it is by this and other local anæsthetics that irregular practitioners open up, straighten, drain, and cure many cases of fistula, their patients believing all along that no operation has been done.

The large majority of perirectal abscesses that eventuate in fistulæ would be cured, even though they originate in rectal perforation, by early and free external drainage, together with stimulating antiseptic washes; but it is not this class of cases that we have to deal with at present.

Fistula may be described as a chronic abscess about the anus. With an opening upon the skin only, it is called blind external fistula; with an opening into the gut only, it is called blind internal fistula; with openings in both, it is called complete fistula. The size of this abscess cavity varies in the different stages and varieties of fistula. In the blind internal variety it is usually large and contains more or less pus and sometimes gas or faecal matter. In the blind external variety the cavity is usually of considerable size in its first stage, extending up and around the gut, and more or less contracted in the second stage, according to the size of the opening upon the skin and its consequent

* Read before the Section in Genito-urinary Surgery of the New York Academy of Medicine, November 10, 1892.

free or limited discharge. In the complete variety it is more of a tubular canal than a cavity, except where it has resulted from blind internal fistula, or in those cases of horse-shoe and very tortuous fistula, when we may see both conditions—a large abscess cavity in one part and a tubular canal in another part of the tract.

In speaking of this subject I shall divide the simple fistula, according to Mollière, into subcutaneous and submucous. The subcutaneous pass between the skin or mucous membrane and the muscles of the rectum. They are usually tubular, short, and with small abscess cavities. They rarely extend above the internal sphincter. The submucous fistulae pass outside of the muscles of the rectum. They are irregular in their shape and course and may open at almost inconceivable distances from the anal region, some interesting examples of which I shall mention later on. The tract may be tubular or sacculated, indurated or soft. When they have an internal opening it is in the large majority of cases between the two sphincters, but it may be at any point within the length of the rectum. Both varieties may be blind internal, blind external, or complete. The symptomatology and aetiology I do not propose to speak of at this time.

Excepting traumatic, which are very rare, all fistulae arise either in ulceration or perforation of the rectum or in suppurative processes in the perirectal tissues.

However arising, the pathology of fistula is the same, excepting, of course, the specific forms of tubercular, carcinomatous, and syphilitic; it consists in a cavity or tract lined with a smooth granulation tissue, which is exactly analogous to that found lining the interior of a chronic abscess. The leucocytes forming the surface of this membrane are loosely adherent, and, constantly becoming free, form the chief part of the pus which drains from the fistula (Cripps). Beneath this granulation tissue and forming its base is a layer of fibrous tissue more or less thick and dense, according to the age of the fistula and the degree of inflammation which the parts have undergone. These granulations are said to be unhealthy, degenerated, "lardaceous" (Kelsey), and would not unite even were the walls in contact, and are generally considered the cause of the fistulae not healing. It is only the superficial ones, however, that are absolutely so, for down at their base these granulations seem to be healthy enough, only becoming unhealthy as they build themselves one upon the other, owing to the poor return circulation in these parts when the patients are up and about. If this were the only cause of non-union, and if all the granulations were unhealthy, the simple section of the rectal wall of the tract would not produce healing as often as it does, for that cutting does not touch the external wall. Again, it is said that fistulae do not heal because of the constant motion of the parts upon each other, thereby preventing their adhesion, and that section of the sphincters prevents this motion and allows healing (Ball, *Diseases of the Rectum and Anus*, p. 73). If this rest is all that is needed, can it not be obtained by a less severe method and one that is not attended by the dangers of such serious after-effects as cutting?

The truth is, these granulations, having a very poor

blood supply, have not the vitality to fill up a large space, and consequently degenerate before they meet in the center to unite the walls of the cavity. If the walls were close together throughout their entire area and kept at rest, and if the superficial, unhealthy granulations were scraped off, there would be no difficulty or delay in union. But the sphincters and the circular muscular fibers of the intestine, being constantly in a state of more or less contraction, draw the rectal wall of the fistula away from the external wall, and thus prevent union or break it up where it has occurred.

The rationale of the treatment of fistula is therefore to vitalize the granulation lining of the cavity and bring the walls in close contact with one another, at the same time making them as immobile as possible. Of course this can not be done if pus, gas, or other secretions are retained in the cavity, and it therefore involves the free external drainage of the tract; its tortuosities must be straightened out into one linear canal from its highest to its lowest point, at which there must be a free external opening. A formulated answer to How can all this be done? may be stated as follows: Convert the fistula into a cone-shaped cavity with its external opening for a base, scrape it out thoroughly, cauterize the surface, and paralyze temporarily the sphincters and gut as high up as the highest point of the fistula by stretching.

It will be seen from this that I am not in favor of the routine practice of cutting into the rectal wall at the highest point of the fistula and bringing the incision out at the anus. This doctrine and its natural sequence—"where the fistulous tract is separated from the rectal cavity by only a thin wall, force the director through into the gut at the highest point and cut straight out"—are not only dangerous both as to immediate and after results, but fail as often as they succeed. By it the pathological opening is generally left untouched. Excluding malignant disease, tuberculous and syphilitic cases, and cases in which previous operations have been done, I have yet to see a blind external fistula that can not be cured without opening into the gut, and I believe that where no pathological opening exists in the gut we are reprehensible for making one. This practice is not only dangerous in itself, but leads to carelessness in searching for pathological openings, and these are often overlooked where patient and persistent search would find them. In the past two years I have operated on five cases in which this operation had been performed and failed to cure. In each of these, by carefully laying open the tract, I was able to find the internal opening, and in no case was it within half an inch of the surgeon's previous incision, thus leaving a fistulous tract of this length or more untouched (Fig. 1). Not only were these cases not cured, but one was left with stricture of the rectum, one with rectal ulceration which it was very difficult to make heal, and one with partial incontinence.

The cause of incontinence is a much-discussed subject. In all the cases I have seen there has been cicatricial tissue at one or more points of the internal sphincter which interfered with the flexibility of the latter and prevented its closing. I believe the size and character of this cicatrix is the most important element in the production of inconti-

nence. Moreover, I have observed that these cases which show partial incontinence (I have never had a case of complete incontinence follow an operation for fistula) have been

FIG. 1.—A, external opening; B, internal opening; C, original external opening and line of surgeon's incision.

cases with large abscess cavities about the rectum, and this fact is borne out by my inquiries of patients who have suffered from incontinence after operations by other surgeons. The explanation of this is, the area of the outside wall of the abscess cavity exceeds that of the rectal wall just in proportion to the size of the abscess, and when the rectal wall is cut through it falls out against the external wall, failing to cover just that difference in area, according to Fig. 2. This must then be filled in by granulation tissue,

FIG. 2.—a, external opening; c, internal opening; b, d, original line of incision; e, c, portion of fistulous tract left untouched.

The treatment which I have practiced of late, therefore, differs somewhat from that laid down in the books, and will find able opponents; but my cases get well without confinement or incontinence, and its only drawback is the inability to obtain for it the same munificent fees that are obtained for operations under anesthetics.

Subtegumentary Fistula.—These little fistulae usually heal so quickly after being cut that one scarcely considers another method until he has seen one failure or a painful, obstinate fissure follow it. Having seen such results more than once, I have come to regard other methods as more effectual. If they are complete or incomplete, I wash them out thoroughly with a 1-to-1,000 solution of mercuric chloride or a fifteen-volume solution of peroxide of hydrogen.

I then inject them with equal parts of tincture of iodine and carbolic acid, or with a ten-per-cent. solution of nitrate of silver, and apply a compress of soft cotton. Burrowing tracts must be looked after and treated in the same manner. Rarely do I find a fistula of the subtegumentary variety that will not heal in ten or fifteen days by this method. It is well to stretch the sphincters as far as the patient will bear it without an anesthetic before applying the cautery, and to have the bowels well emptied in order that they may be confined for three or four days afterward. If

FIG. 2.—a b c, abscess cavity; a c e d, rectal cavity; f b g, space uncovered by edges of the rectal wall.

this should not succeed, little time will be lost, and we may then resort to the elastic ligature, which has succeeded in every case of this variety of fistula in which I have tried it. While I have not seen it do so, I believe the ligature may produce the same results as cutting, and this, together with the fact that it can not be used easily in blind or burrowing fistulae, makes me prefer the above described method to it. Where the tract is very short, superficial, and entirely outside of the anus, there is no objection to cutting, unless the patient offers it, and the results are rapid and satisfactory. Where possible, it should always be done with scissors. Where the fistula involves the anal orifice or any portion of the rectum, the injection method is the simplest, safest, and equally as sure. If the tract be entirely within the sphincter, it may still be treated by the injection and cautery method through either my own or O'Neil's speculum, whereas in this location the cutting operation can only be done under general anesthesia.

Submuscular Fistula.—This is a much more serious form of the disease, and a book of no mean proportions might be written on the different methods that have been devised for its relief. I shall consume no time in a review of such, but simply detail the methods which I have found satisfactory by personal experience. First of all, in determining the form of these fistulae, whether complete, blind internal, or blind external, a probe is seldom necessary. The educated touch will find the internal opening of a fistula more accurately and with less pain than any probe. The latter is most useful, however, in treatment for following up burrowing sinuses and straightening out the tract, but I rarely use it until the patient has been cocainized or anesthetized. In the blind external form, where there is no opening into the gut, the majority of the cases should be cured without making one. Communication with the gut subjects the freshly cut and curetted surfaces to infection by fecal matter and delays, by irritation, the healing even where sepsis does not occur. The abscess cavity should be freely opened by a circular incision about the anus, the sphincters stretched, the cavity curetted and cauterized with carbolic acid and iodine, and then lightly packed for twenty-four hours with antiseptic gauze. It is important that the procedures be carried out in the order mentioned, for stretching the sphincters before freely opening the abscess may cause by its tension a break in the rectal wall,

and the same danger exists in stretching after having curetted the abscess cavity and thus thinned its rectal wall. The packing should not be kept in over twenty-four hours, as it only holds the walls apart and prevents their healing rapidly. A probe-pointed syringe should be gently passed to the bottom of the wound each day and the parts irrigated with a 1-to-2,000 bichloride solution. Occasionally it will be necessary to stimulate healing in large abscess cavities by applying the iodine and carbolic acid a second or third time; but this is rare.

Blind internal fistulæ are nearly all associated with abscess cavities of considerable size. Most of these cavities extend downward toward the perineum, and with a flexible probe and proper speculum we can make out the point at which they most nearly approach the surface. These should be converted into complete fistulæ and treated accordingly. If the abscess cavity does not point downward, however, the case resolves itself into an intrarectal abscess, and it may be treated by stretching the sphincters thoroughly, opening, curetting, and cauterizing its cavity. The patient should be confined to bed, the bowels opened daily, and the rectum irrigated twice a day with a fifty-per-cent. saturated solution of boric acid.

Complete submuscular fistulæ have their internal opening, in the majority of cases, between the two sphincters. Where such is the case and where no abscess cavity has burrowed upward beside the rectum, the rubber ligature has proved in my hands a most satisfactory treatment. The ligature, however, should never be passed through a tortuous tract. The circumanal tissues should be cocaineized and the fistula opened to a point immediately below its internal opening. By this the tissues to be cut through by the ligature will be decreased, the fibers of the external sphincters will be cut squarely across, and there will be less danger of disabling even this muscle. Before the ligature is applied the cutaneous tissue in its track should be cocaineized and cut through with a knife in order to avoid the pain which this procedure sometimes causes. When the abscess cavity has burrowed upward, or where the fistulous tract has passed outside of the internal sphincter and opened into the gut above that muscle, this treatment must be modified. It is in these cases, when treated by the ligature or ordinary cutting operation, that we meet the dangers of incontinence and rectal ulcerations as described above. Minimize them as we may, they are actual dangers and should be avoided, if possible, in our practice. It is my custom, therefore, to reserve these procedures as a last resort. After making a very free external opening of the fistulous cavity, the sphincters and the gut should be thoroughly stretched as high up as the highest point of the cavity; the internal orifice should then be found and thoroughly curetted, together with the rest of the abscess walls. This opening should then be tightly packed from the fistulous side with a narrow strip of iodoform gauze and a small piece of the same laid over the orifice on the rectal side through a Sims vaginal speculum; the fistulous cavity should be tightly packed with the same material. The bowels should be confined and the patient kept perfectly quiet for five or six days. By this time the internal orifice will

be entirely closed or healthy granulation will have been established, which will proceed to accomplish the same result promptly. The packing should be renewed from the fistulous side on the third or fourth day. After the internal orifice has healed, all packing should be discontinued and the cavity treated by irrigation as in blind external fistula. I have not had this method fail me save once, and that in a patient who would not bear restraint. In his case the tract being perfectly straight and ready for the ligature, it was applied and a happy result soon followed. It follows naturally that where the fistulous walls have been rendered healthy by the thorough draining and curetting the cure will be more prompt if for any cause the ligature or cutting operation must needs be done.

FIG. 3 a, external opening; b, opening into urethra; c, tract encircling right side of anus.

The importance of finding the internal opening of a fistula and never opening the gut until it has been found is well illustrated in the following case (Fig. 3):

Mr. S., aged twenty-four, was brought to my office on August 3, 1891, by his physician, who said the patient had a fistula that would not heal and needed to be operated on. He was very sensitive to pain, and at his request I decided to give him chloroform and operate in my office, the doctor having assured me that it was a small affair and that it could be safely done there. The fistulous abscess almost entirely surrounded the rectum, running up along its side so closely that only the thinned rectal wall intervened between the two cavities. After laying it freely open and searching carefully I failed to find any opening into the gut. I therefore stretched the sphincters and scraped and cauterized the cavity and sent the patient home. At first the wound did well and looked as if it would promptly heal; but noticing an unusual moisture about it, I became suspicious of it and adopted the following expedient: Having thoroughly cleansed and dried the cavity, I had the patient urinate, and in the midst of the act shut off the stream at the mentus. After a few moments I examined the cavity again and found in it something like fifteen drops of urine. The case was, of course, one of urinary fistula, but the tract leading up to it was so small that only the finest eye probe could be made to enter it. Had I followed the usual routine the rectal wall and both the sphincters would have been uselessly cut and the after-effects would undoubtedly have been bad.

Complicated Fistulæ.—Of these, the more important varieties are—long, tortuous fistulæ opening at distant

points; horseshoe fistulae; watering-pot fistulae; recto-vaginal fistulae; recto-vesical fistulae.

Long, Tortuous Fistulae.—It is remarkable to see what a deep, long, burrowing, tortuous tract may result from a small internal fistulous opening situated just within the external sphincter. I have seen two of these tracts opening at the upper border of the sacrum and one upon the anterior aspect of the trochanter major, all of which began between the external and internal sphincters. Imagination can scarcely limit their possibilities, for no membrane or fascia seems to hedge them in. Where they burrow subcutaneously, as in the following case, taken from my notebook, they are easily dealt with:

Mr. T., aged thirty-five, has had fistula for five years. It was much swollen at one time and has always been painful. No tubercular, carcinomatous, or syphilitic history. No stricture, hæmorrhoids, or other disease of the rectum. Small crater-like ulcer can be felt and seen through the speculum, half an inch inside of the external sphincter on the right side, from which, on pressure over the sacrum, there exudes a drop of pus. There are two fistulous openings—one about the middle, the other at the upper border of the sacrum and almost in its center.

The fistulous tract being superficial, it was laid open from above downward. It passed first to the left side of the rectum, then doubled upon itself and entered through the right side at

above the anus. Internal orifice can be felt on the left side and between the two sphincters. (Fig. 5.)

FIG. 5.

Operation.—The external opening was enlarged and a No. 12 F. steel sound introduced into the tract to the point near the sacrum. This was cut down upon and a free counter-opening made at this point. The fistula was followed down from here and laid open inch by inch to the internal opening. The upper tract beneath the muscle was scraped out, a drainage-tube inserted, and the wound dressed antiseptically. Patient was kept in bed two weeks, and made a good recovery at the end of four. The large amount of induration about the thigh and buttocks soon began to be absorbed, and at the end of four months it was entirely gone.

It is then unnecessary to cut through these large masses of tissue always. The counter-opening, drainage, and proper treatment of the proximal end of the fistula will cause the distal tract to heal, and save the patient much shock and loss of time. This case brings up the management of those cases in which there are large masses of cicatricial or connective tissue about the fistulous tract. It is held by many that it is impossible for the fistula to heal while this remains. This appears to me to be putting the cart before the horse. The fistula is the cause of this growth of tissue, and not vice versa. To cure a disease, remove the cause if it still be existing and effective. It is surprising how rapidly and completely these masses will be absorbed when the fistulous tract has been properly closed, and while an incision into them in two or three directions may hasten their removal, neither this nor dissecting them out is necessary to the cure of the fistula.

Horseshoe Fistula.—This expression was originally employed to describe a fistula surrounding the posterior part of the rectum, with one internal opening in the center of

FIG. 4.

the point mentioned. (See Fig. 4.) Some fibrous tissue was dissected out from the bottom of the tract, the wound packed with iodoform gauze, and the patient was well in three weeks.

The following case, however, was more interesting, showing how these tracts may involve important tissues:

Mr. R., aged fifty, Italian. Had an abscess about anus five years ago. It broke, discharged, and healed up. After six months he began to suffer pain in his back and right side of the pelvis. The pain extended around to his hip and he found much pain upon walking or standing erect. A small lump formed on the outer aspect of his thigh, which finally opened and discharged considerable pus. About this time he also noticed a discharge about the anus. This condition still exists.

There is a fistulous opening upon the thigh at the point above mentioned, and a probe introduced here runs transversely backward close to the hip, beneath the gluteus maximus muscle, the gluteal artery, and the lesser sciatic nerve, to a point about an inch anterior to the border of the sacrum and five inches

the gut behind and one external opening on either side of the tendon of the external sphincter. It has, however, come to signify any perirectal abscess surrounding the posterior wall of the rectum with one or more fistulous openings into it. It may therefore be a complete, blind internal, or blind external fistula. The abscess cavity is usually hour-glass shaped, connected in the center by a narrow channel running between the tendons of the levator ani and external sphincter muscles. There may be one or more internal openings or none, and one or more or no external openings, only one of either kind being necessary to constitute a fistula. The point of the gut or skin at which these openings are found is variable both as to the circumference and height.

The following case will illustrate the condition and its treatment:

Mr. L., aged twenty-six, was sent to me by his physician in December last with the following history: Some four months previously he had been troubled with an ischiorectal abscess on the left side which was opened by the doctor and healed very soon without any complications. About two months later he began to suffer pain in that region again, and soon noticed induration and swelling on the right side. This was also pronounced an abscess at the time, but, notwithstanding every precaution on the part of the patient and the assiduous attention of the doctor, it would not heal. He being very sensitive to pain, I agreed to examine him and operate at the same time, and did so on December 28th, using ether as an anæsthetic. The probe ran into the abscess cavity on the right side five inches and a half upward and impinged upon the thinned wall

FIG. 6.

of the gut (Fig. 6), but I could find no opening into the rectal cavity. Enlarging the external opening by a circular incision around the posterior border of the anus, I found a narrow tract running behind the rectum about three fourths of an inch above the margin of the anus, and entering into a cavity on the left side.

This cavity was closed in

by only the united skin at the point of the old incision. I cut down upon the probe at this point and, enlarging the incision, converted this into a cone-shaped cavity with apex upward. Failing still to find an opening into the gut, I dilated the sphincters thoroughly and searched the inside of the rectum for it, but in vain. I then scraped out the cavities thoroughly, cauterized them, and packed them lightly with iodoform gauze. The patient being in an anæmic, run-down condition, the parts healed slowly, but at the end of ten weeks he was well. The packing was only introduced three or four times after the operation, irrigation being depended on to keep the parts clean and free from pockets. Cutting the gut in this case would have necessitated a double section of the sphincters to be thorough, and, from the size of the abscess cavity, I am sure would have resulted in incontinence. Had I found an internal opening below the internal sphincter I should have laid the gut open from this point out, but had it been above the internal sphincter I should have scraped and cauterized it only, trusting to granulation healing it rather than run the risk of incontinence and stricture.

Watering-pot Fistula.—This term has been applied to fistulae having several external openings. These openings are usually connected with one large abscess cavity by long or short fistulous tracts. Their management consists in laying these several tracts open up to the main abscess cavity, which is then treated as a simple complete or blind external fistula. But sometimes this involves the destruction of too much tissue and subjects the debilitated patient to great shock. Under these circumstances it is better to locate the main abscess cavity by introducing several probes in the different openings and cutting down upon them at the point of their convergence, lay open the cavity freely, and treat it as a simple fistula from this point. The several tracts are then treated by scraping, cauterization, and drainage. By these means I have succeeded in curing two cases with very small incisions, where the laying open of the several tracts would have involved a large amount of tissue, the healing of which would at least have been doubtful owing to the debilitated condition of the patients. Where the tracts involved are short, however, and the tissues involved are not great, it is better to lay them all open.

If there are two or more openings into the rectum and it is found necessary to cut into the gut, only one point should be cut at a time, as double section of the sphincter is frequently followed by incontinence or stricture. In the majority of cases the other tracts will heal when one has been cut through, and the results are much more satisfactory.

Recto-vaginal Fistula.—This variety comes under the observation of the gynecologist much more frequently than under that of the rectal surgeon. They are usually due to pressure or traumatism at childbirth or to syphilis. Injury by instruments, pressure from foreign bodies in the vagina or rectum, recto-vaginal or vulvar abscesses, or ulceration of the glands of Bartholin may all cause it. Dr. Emmet believes it frequently due to phagedenic syphilitic ulceration. It may be high up or low down in the vagina, large or small; but, with the exception of those just below Douglas's *cul-de-sac*, where there is only a very thin space between the rectum and vagina, they usually run an oblique course. The abscess cavity is generally small and may be cannular and lined with reflected mucous membrane from the vagina. The opening in the vagina may sometimes be very hard to find, owing to the valve-like folds of its upper border, but the educated touch can usually make out the rectal opening without great difficulty. Where there is escape of gas and fecal matter through the vagina an intense erythrit is likely to be developed.

Many plans of procedure have been devised for the treatment of these conditions. Cauterizing occasionally cures, but the tract should be first scraped and the sphincters dilated. No treatment for fistula offers any assurance of cure without this last precaution. Denudation and suturing as for vesico-vaginal fistula, either upon the vaginal or rectal surface, have long been practiced, but can not be said to be satisfactory. Failures are as frequent as cures by this method.

Dr. John Rhea Barton (*Amer. Jour. of the Med. Sc.*, 1839,

p. 305) first published his device for the cure of this condition which has been appropriated by a number of the profession, and improved in detail by Dr. Isaac E. Taylor, of this city. This operation consists in connecting the fistulous tract, at a point near the rectum, with a counter-opening in the perinæum, thus forming a complete recto-perineal fistula as well as a vagino-perineal fistula. The recto-perineal fistula is then treated as an ordinary fistula involving the same tissues, by ligation, section, or scraping and dilating the sphincters. The vaginal portion of the fistula is scraped out, cauterized, and left to heal by granulation, which it generally does promptly and without any complications. Since, however, intestinal antisepsis has become a possibility, and we can do a plastic operation about the rectum with comparative assurance of immediate union, I have been practicing the method devised by Saucerotte in 1798. As perfected, the operation consists in the careful preparation of the patient for several days by dieting, daily laxatives, and the administration of naphthol and salicylate of bismuth in full doses three or four times a day. In addition to this, the rectum and vagina are irrigated twice a day with a saturated solution of boric acid. When the patient has been anesthetized the parts are scrubbed and cleaned antiseptically, the perinæum is cut through from the outside by a straight incision into the fistulous tract, a stiff grooved director previously introduced into the tract guides the operator in the line of incision. The perinæum having been divided, the fistulous tract is dissected out and the wound is treated as a complete perineorrhaphy. The rectal mucous membrane is first carefully sutured with chromicized gut, the divided ends of the sphincters are picked up and united by the same, the perinæum is drawn together by deep silver-wire or silk-worm-gut sutures, introduced after the manner of Dr. Cleveland, and the mucous membrane of the vagina is sutured with interrupted silk sutures. The parts are then dressed with iodoform gauze in the vagina, a tube is placed in the rectum for the escape of gas and iodoform gauze is placed well up around it and over the perinæum, and the knees are tied together. The bowels are confined for two days only, as I believe that more harm results from large, hard stools than from early soft movements. Following each movement, and at least twice a day after the first forty-eight hours, the rectum is irrigated through a

FIG. 7.

rectal irrigator with the saturated boric-acid solution. The irrigator which I use and which is here depicted is a very valuable instrument in the general treatment of rectal diseases, and it is light, easily cleansed, and inexpensive.

The patient is kept in bed for two to three weeks by this operation, the perineal and vaginal stitches being removed about the seventh day, and recovery may be considered established at the end of about four weeks. This is the one exception in which dissection and immediate union of a

fistula are feasible and scientific, except perhaps those cases of straight tubular tracts where the angular wound left after dissection can be easily drawn together. The difficulty of dissecting out the different burrowings of tortuous fistula, the uncertainty of proper apposition and still more of union, and the length of time necessary, make this method undesirable, to say the least, save in most exceptional cases. The rapidity of cure where it succeeds is brilliant to be sure, but it does not justify the risk it involves.

Recto-vesical and Recto-urethral Fistulae.—In the first of these the tract is generally very short. They are due to congenital defect, injury during lithotomy, ulceration, malignant growths, or pressure of a stone in the bladder. Where the opening is low enough down to be reached through the rectum it is proper in these cases to operate as in vesico-vaginal fistula. Cauterization with nitrate of silver or the Paquelin cautery may succeed in many small openings, but as a rule it is only time lost to try it. When the tract is long and oblique, running from the bladder to an opening low down in the rectum, a counter-opening in the perinæum should be made, as in recto-vaginal fistula, and the rectal portion of the fistula treated by the ligature or cautery; the vesical portion should then be treated by stimulation and cauterization, if necessary resorting to perineal section and drainage of the bladder.

In urethro-rectal fistula we have an entirely different condition to deal with. The tract is longer and more tortuous, there is more or less of an abscess cavity, the dribbling of the urine through it is not constant, but periodical with the calls to urination. Its most frequent causes are stricture of the anterior urethra; accidental wounds of the rectum in operations on or through the perinæum; perforation of the rectal and urethral walls by foreign bodies in one organ or the other; abscesses of the prostate or between the rectum and urethra; calculi arrested in the prostatic or membranous portion of the urethra; deep ulcerations of the urethra [?] or malignant growths. The success of treatment in these cases will depend largely upon the cause of the condition. It is needless to say that no operative procedure—nothing, in fact, but palliative treatment—should be directed to the fistula itself in either of the last two varieties when due to malignant growth. It is almost useless to say that when due to stricture of the urethra this should be removed before we can hope to cure the fistula. In this variety I believe in conjoined internal urethrotomy and perineal section after the manner of Harrison, at the same time stretching the sphincters, scraping out and cauterizing the rectal end of the fistula, or, if the rectal opening be of considerable size, closing it up with silver-wire sutures, as in the operation for vesico-vaginal fistula. If the fistula be due to abscess, either perineal or prostatic, the proper course to pursue will be to make a thorough opening of the cavity through the perinæum, scrape it out, and treat the condition as two separate fistulae—the rectal by dilatation of the sphincters and packing with or without the rubber ligature, and the urethral by drainage and packing as is practiced by genito-urinary surgeons.

SOME PRACTICAL POINTS REGARDING THE EXCESSIVE EXCRETION OF URIC ACID.*

By C. A. HERTER, M.D.,

PROFESSOR OF THE ANATOMY AND PATHOLOGY OF THE NERVOUS SYSTEM
IN THE NEW YORK POLYCLINIC.

ON looking over the records of determinations of uric acid made in my laboratory during the past two years, it occurred to me that it might interest this society to learn what conclusions of a practical nature might be reached from a consideration of these records in their relation to the clinical histories of the cases studied.

The number of individuals in whom the uric-acid excretion was studied is a hundred and sixty-three, and the number of determinations, all made by the Ludwig-Salkowski method, is considerably over six hundred.

From so large a number of observations many statements may be made with positiveness, but, in addition to the conclusions which we may consider to be established beyond doubt, there are others that must be advanced with some reserve and that are to be regarded as suggestions resting on more or less acceptable evidence rather than on established facts. But such suggestions, if carefully considered, are often of much value in helping to establish general ideas of a question, and I feel disposed to speak of this, as the subject in point affords considerable material of this character.

The first question that suggests itself for discussion is, What is the significance of the separation in the urine of uric acid or urates? Can any inference be drawn from such separation as to whether uric acid is present in excess or not? This is a question of considerable practical importance, for if the observation of precipitates is of no value whatever, it is high time that this should be generally known. But if, on the other hand, it can be shown that such observation is of value, it is desirable that we should try to fix the range of its use and the nature of its limitations.

The first point to which I would call attention is the fact that we must distinguish between the significance of separated urates and that of separated uric acid. You will pardon me if, in presenting this fact, I remind you of certain things which are well known, in order to make clearer others that are less familiar.

The quantity of uric acid which exists in solution in the urine as free uric acid is so small, if any, that we need scarcely consider it. The uric acid of the urine is present in combination with sodium as urates, or, as Roberts has pretty satisfactorily shown, as quadri-urates—that is, as salts in which a molecule of a bi-urate salt is in loose combination with another molecule of uric acid. The bi-urates do not exist in the urine as such; in fact, they exist nowhere in the body under normal conditions and are only found in the topoi of gout. The separation of the quadri-urates from the urine as amorphous urates is merely a question of solubility. As is well known, a large quantity in a given volume and a low temperature favor this separation, and it is an important fact that one does not often

meet with a separation of urates in a twenty-four-hour sample of urine unless the uric acid is in actual and decided excess. In looking over my records I find that, with very few exceptions, the urines from which the urates had separated contained a greater proportion of uric acid than belongs to health. We come therefore to the conclusion that a deposition of urates in a sample of twenty-four-hour urine is pretty reliable evidence that the uric acid is in excess.

The case is very different with urines in which there has been a separation of uric-acid crystals. While in the case of the urates the separation is dependent merely upon insolubility, in the case of free uric acid the separation depends upon a process of decomposition of the quadri-urates, a fact which has been brought out by Roberts in his recent Croonian lectures. A quantity of amorphous urates—that is, quadri-urates—is carefully prepared from fresh urine and dissolved in distilled water (by heating to boiling and constant stirring). This is set aside for twenty-four hours. During this time a quantity of uric-acid crystals separate and the amount is not increased on further standing. Now, it is a fact of considerable interest that analysis shows the amount of free uric acid in the sediment to be equal to the quantity of uric acid that remains in solution as a urate. The explanation of this is that the amorphous urates, consisting of quadri-urates of sodium, potassium, and calcium, give up one of the two molecules of uric acid of which they are composed, the other molecule remaining in more stable combination with the bases as bi-urates, so that we now have in solution one half the amount of uric acid in combination with the whole of the base present in the quadri-urate. A similar decomposition occurs in the urine itself, but, as the urine contains many mineral substances in solution, the process is modified and is more complex than in a pure solution. Among the most important of these mineral salts are the phosphates of the alkali metals, which in great degree regulate the reaction of the urine—the urine being acid when monobasic phosphates or monometallic salts preponderate, alkaline when the dibasic phosphates are in excess. The manner in which the uric-acid separation is effected is as follows: First, the water of the urine causes the decomposition of the quadri-urates into uric acid and bi-urates. In this way one half the uric acid is set free, as in the case of the free aqueous solution above mentioned. Now, the bi-urate which remains is at once transformed in the presence of the monobasic phosphates (acid) into a quadri-urate, for by a double decomposition two atoms of bi-urate with one of acid phosphate change into one molecule of quadri-urate and one of dimetallic phosphate as follows:

This process of decomposition and recombination goes on in an acid urine until all the uric acid has been liberated.

From what has just been said, it is clear that the acidity of the urine is an important factor in determining the depo-

* Read before the New York Clinical Society, May 26, 1893.

sition of uric acid. In fact, every acid urine, if protected against putrefaction, will deposit most of its uric acid in the course of time. The rapidity of the deposition, of course, varies greatly, but every acid urine has a tendency to deposit its uric acid. Certain influences are, however, at work to inhibit and delay this liberation. Important among these influences is that of the saline constituents of the urine, especially the neutral dipotassic phosphates, which in very small amounts have a pronounced inhibitory action. Another influence of importance is that of the coloring matter. Urines rich in coloring matters deposit their uric acid more slowly, other conditions being similar, than those which are light in color; and urines deprived of their coloring matter by filtration through animal charcoal show a much more rapid decomposition of the quadrurates than before filtration. We must thus recognize numerous influences at work in determining the precipitation of uric acid—influences which we must admit to be only imperfectly understood, but among which it seems fair to regard the factor of acidity as the most important. It requires no argument to show the important bearing of these conditions upon the formation of uric-acid calculi, but this is a subject aside from the present line of inquiry. What chiefly concerns us here is the fact that in many urines which contain no excess of uric acid a sediment is formed soon after or even before the urine leaves the bladder. Of course, urines that contain a large amount of uric acid per unit volume are more liable to deposit a uric-acid sediment than urine containing a smaller amount, everything else being equal. But the point to be emphasized is that other influences are so great that the difference in the amount of uric acid present has little to do in deciding the result. I noted with interest, on looking over my records, the circumstance that of the urines in which uric acid was deposited soon after the bladder was emptied, there were many more urines in which the uric-acid content was normal than in which it was excessive. We may therefore come to the two following conclusions without much hesitation:

1. That a urine from which there is an early separation of uric acid gives us no real reason to think that the actual content of uric acid is excessive.

2. That a urine from which the urates separate gives us good reason to believe that there is an actual excess of uric acid, and that this probability is increased if the density of the urine is less than 1.025.

Unfortunately, the converse of the latter statement is not true; we can not conclude from the circumstance that a urine does not deposit its urates that it does not contain too much uric acid. How far this is from being true is shown by the fact that a very large majority (more than three quarters) of all the urines with excessive uric acid of which I have records did not deposit their urates.

In speaking of an excessive or normal excretion of uric acid, it has been assumed that we possess a standard for comparison on which reliance can be placed. This standard is the ratio of the uric acid excreted in the twenty-four hours to the urea excreted in the twenty-four hours. As already pointed out elsewhere, the ratio of uric acid to

urea, in a healthy adult upon a mixed diet, varies little from day to day. In different individuals the fluctuations in health are considerably wider, but not so wide as one might expect. The statement was made by me a year ago that the normal ratios had been found to vary from 1 to 45 to 1 to 55 or 60. Since then many more individuals have been studied, and it may be safely stated on the strength of this experience that the normal ratio is expressed by these figures. In most healthy individuals the proportion is not far from 1 to 50. Instances certainly occur in which the ratio averages somewhat higher than 1 to 45 in persons whose health is apparently of the best, but this is so exceptional that we need scarcely take account of it. Whenever the ratios of an individual average higher than 1 to 40 we are justified in regarding this case as one in which an excess of uric acid is being excreted. Whenever the ratio runs higher than 1 to 35 the excess of uric acid is to be considered large. I have never met with continuous ratios so high as this except in persons whose health was distinctly impaired. A proportion of uric acid to urea higher than 1 to 30 indicates very great excess of uric acid, and is only rarely observed. A ratio higher than 1 to 20 I have never found.

I wish now to ask your attention for a few minutes to some points regarding the clinical and pathological significance of excessive uric-acid excretion. This subject is, to my mind, more interesting than any other connected with the uric-acid problem—far more interesting, for example, than the purely chemical considerations that refer to the separation of uric acid from the urine.

The first point of general interest which I should like to emphasize is what may almost be called the universality of uric-acid excess in functional disease. I know of nothing in connection with my work upon this subject that caused me greater surprise than the constantly increasing category of maladies in which too much uric acid was found. It is not my intention to consider here in detail the individual morbid states that are associated with too great an output of uric acid, but rather to touch upon the distribution of these states in their wider relation to the subject under consideration. It is convenient to group the cases in which too great an output of uric acid is found in two general classes, the first comprising those cases where the excess is of continuous occurrence, the second those where the excess is of transient duration. In the first category are to be found, in my experience, every case with pronounced neurasthenic symptoms, most cases of simple anæmia, probably most blood diseases, certainly leucæmia, most cases of chronic gastric dyspepsia, most cases of chronic intestinal indigestion, cases of *petit mal*, many cases of chronic nephritis, many cases of phthisis, and chronic febrile states generally. This list might be extended almost indefinitely, but the extension would serve to confuse the subject rather than clear it. For example, most phthisical patients excrete a good deal more uric acid than they ought, but it is not at all clear that this excess is related to the tubercular process in the lung; it is far more likely that the excess depends upon the fever, or upon the digestive derangements, or upon the associated

anæmia. Similarly, in cases of chronic nephritis it is more than probable that the increased output is related to the accompanying anæmia. It would certainly do much to clarify our understanding upon this subject if it could be shown that in all these apparently varied conditions there is a single underlying condition to which the increased output of uric acid might be referred. There are, indeed, some facts to which I shall later make reference, which suggest the view that the excessive uric acid elimination usually bears a definite relation to a state of leucocytosis, but, unfortunately, we are not in a position to more than hint at the possibility of this being so. We must content ourselves for the present with the knowledge that anæmia is one of the important associations, or causes, if you prefer, of excessive uric-acid output, and that this may be at the bottom of a large proportion of the chronic states we are considering. I have been surprised to find how many neurasthenics whom there was no reason to think anæmic have shown a decidedly reduced proportion of hæmoglobin. But while it is possible that we should refer to anæmia the excess of uric acid in some neurasthenics, it is more likely that in most of these cases the excess depends upon the associated disorders of digestion.

The conditions in which there is a transient excess in the output of uric acid are varied. Any acute disorder of gastric or intestinal digestion appears sufficient to increase temporarily the elimination of uric acid. A very large meal often increases considerably the relative output of uric acid for twelve, twenty-four, or thirty-six hours in a perfectly normal individual and without giving rise to any appreciable disorder of digestion. The use of a considerable quantity of alcohol has the same effect, which is especially pronounced in the case of wines that contain much sugar. The effect of a large amount of sugar (eight to sixteen ounces of saccharose a day) is apparently to increase uric-acid excretion. It is important to note here that the influences just mentioned are much more operative in producing an excessive output of uric acid in persons whose uric acid is habitually a little in excess than in persons who are quite normal in their output. Other conditions that are associated with a temporary increase of the uric-acid output are the following: Almost any form of functional headache, including the migraine paroxysm, and seizures of *grand mal* (the increase being present in these cases on the first or second day after the seizure).

The occurrence of excessive uric-acid elimination in so many apparently different conditions leads one to inquire whether these conditions have any clinical feature in common through which they may be related to the uric-acid excess. Apparently, all that can be said in this connection is that all, or nearly all, the states which are characterized by uric-acid excess are associated with signs of some disturbance of general nutrition, and it may be said, in general, that the greater the excess the more pronounced are the evidences of nutritive disorder. We are not yet in a position to assert that the converse of this holds good—that all, or nearly all, disturbances of nutrition are accompanied by an increased uric-acid output—yet I can not but suspect that a very great extension of our observations would lead

to the view that there are few derangements of nutrition, whether transient or prolonged, which fail to exhibit some degree of this excess. If we accept this view of the clinical meaning of uric-acid excess, it is clear that this conception must modify not a little some of the currently accepted notions, one might almost say prejudices, upon this subject. It becomes necessary to do away entirely with the idea that uric-acid excess is related specifically to any particular clinical state, and it leads us to inquire into our use of certain current expressions which have originated in misconceptions and have been passed on from writer to writer. After what has been said, it requires no argument to show that the expression "uric-acid diathesis" is one that should be used as little as possible, or, if used at all, should be used with a clear understanding of the vagueness of the term. What right have we to speak of a "uric-acid diathesis" as a condition in any way distinctive, when we know that an excessive output of uric acid is merely one of the expressions of a great variety of nutritional disturbances? What can be meant by the expression more than such excessive elimination continued for a considerable period of time? The word diathesis in this connection is deprived of any special meaning, and, to my understanding, had better be used for clinical states having more fixed characters if it is to retain any meaning at all. Another expression which appears to me objectionable is "lithæmia," as ordinarily employed for designating the excess of uric acid in the urine which is construed to mean an excess of uric acid in the blood. For we have seen that uric-acid crystals may separate in the urine when there is no excess whatever of uric acid, and may not separate when there is an excess. When uric-acid crystals separate in the urine soon after it is passed, we may assume that there is some disorder of nutrition back of this separation, which gives rise to it by causing too acid a urine, or one in which the salts or other constituents of the urine are defective. But, while these deviations in composition are surely abnormal, they must be sharply distinguished from the real excess of uric acid which the proper use of the word lithæmia implies. It is better to admit our ignorance of the real nature of these disturbances, and speak merely of an excessively acid urine with separation of uric acid, or of a deposit of urates, than to mask our ignorance with a euphemism like "lithæmia." If we have reason to suspect that the blood actually contains too much uric acid, let us make use of the term "uric acidæmia," suggested by von Jaksch.

Before speaking of the diagnostic and prognostic significance of an excessive uric-acid output, or of the treatment that appears best adapted to it, I should like to make brief reference to certain general physiological and pathological considerations. In the first place, the idea that uric acid is formed in excess in consequence of defective oxidation must be regarded as having no good foundation, although it is a current view. Senator, and also Naunyn and Riess, found that there was no distinct increase in uric acid in dogs in which dyspnoea had been experimentally produced. Bunge, working much more recently, found the uric-acid output in patients with respiratory disease to vary within

the normal limits. The idea that uric acid is a product which is in process of becoming urea is part of the sub-oxidation theory and must fall with it. Of course it is easy to see how, upon paper, the oxidation of solutions of uric acid may be converted into one of urea, but, unfortunately, there is no evidence that this really occurs in the body. Then, again, the view that uric acid is formed by the activity of the renal epithelium must be regarded as mere hypothesis. It is, in fact, one of those opinions that are based merely upon a more or less skillful juggling with chemical possibilities that are suggested by the contemplation of formulæ, unsupported by experimental evidence. Those who formulated this opinion did indeed make use of the supposition that the blood never contains any uric acid. "How is it," said they, "that the blood contains no uric acid if this uric acid is really formed anywhere else in the body than in the kidney?" This view of the problem is, however, upset by the fact that von Jaksch and others have found uric acid in the blood in anæmia and other conditions in appreciable quantities. The reason it is found in health in extremely small quantities only is probably because the small quantity formed is very rapidly eliminated by the kidneys. That the renal epithelium can have little or nothing to do with the formation of uric acid is further shown by the experiments of Schröder, who found that in birds from which the kidneys had been taken uric acid continued present in the blood and accumulated in the liver. The balance of evidence at the present time is strongly in favor of the view that uric acid is formed to a large extent both in the liver and spleen.

Have we any hypothesis as to the significance of uric acid which will take the place of the views which modern research has overturned? Considerable evidence has been accumulated which goes to the support of a hypothesis which is essentially modern and is of general biological interest. It is this: that most or all the uric acid which is excreted is derived from the nuclein in the nuclei of cells throughout the body—especially, according to some, the white blood cells—from the breaking down of these nuclei. As this view is one which is gaining ground and has considerable practical importance, we may briefly review the evidence on which it is based. Much of this evidence has been collected by Horbaczewski in a recent publication. In the first place, it was found that if the pulp of spleen be allowed to commence putrefaction by digesting it for eight hours at a temperature of 50°, the extract obtained yielded xanthine or hypoxanthine on simply boiling. If the digestion was carried further with fresh blood, uric acid was obtained in considerable quantities, 2.5 milligrammes of uric acid having been got from one gramme of the splenic pulp. Further, when the nuclein separated from the splenic pulp undergoes digestion with fresh blood, uric acid is formed. These experiments are very properly interpreted as showing that uric acid, with its allied leucomaines, xanthine and hypoxanthine, can be obtained by the destructive transformation of nuclein. The other tissues of the body, excepting tendons, may be caused to yield uric acid by similar processes, but it is from the white cells of the blood that the major part is derived. This is thought to be

shown by the following facts—namely, that conditions which increase the number of white cells in the blood, and consequently stimulate their destruction as well as formation, coincidentally increase the output of uric acid. If this shall be shown to be true, it will certainly be a strong support to the hypothesis. It is claimed by some that this has already been satisfactorily demonstrated, but we may be pardoned for expressing some caution in accepting this statement, as the evidence that exists appears to us in several respects imperfect.

In detail, the following facts are brought forward to support the above view: If rabbits or starving men are fed on nuclein from spleen pulp, the uric acid elimination is greatly increased. This fact appears hardly to possess the value as evidence attributed to it by Horbaczewski, and does not necessarily show that the uric acid is derived from nuclein, since many substances that derange nutrition could doubtless be shown to have a similar effect. It is claimed further that a marked leucocytosis is induced by the use of nuclein taken by the stomach or hypodermically. Again, when you produce a physiological leucocytosis by giving large amounts of nitrogenous food, there is observed an increase in uric acid; and when this physiological leucocytosis is reduced by diminishing the nitrogenous food, there is a corresponding reduction in the excretion of uric acid. Further, it is broadly held, though I fear with insufficient reason, that drugs which increase leucocytosis, coincidentally increase uric-acid excretion, and, conversely, that drugs which diminish the number of white cells in the blood decrease the uric-acid output. Another fact which is advanced with a view to strengthening the hypothesis of a relation between leucocytosis and uric acid is that the excretion of uric acid is habitually greatest at the time when the blood contains the greatest number of leucocytes—that is, from two to three hours after a meal.

In view of the foregoing evidence, I think we may accept the nuclein view of the origin of uric acid as a working hypothesis, though we require a considerable accession of evidence, including the evidence to be obtained from the study of uric acid in birds and snakes (in which uric acid takes the place of urea), to enable us to accept it as a theory. Since, according to this hypothesis, the formation of uric acid has its origin in a chemico-physical process of such universality as the breaking down of the nuclei of cells, it is not difficult to understand the clinical fact that many different conditions are capable of modifying the output of uric acid, the diverse influences becoming operative through the same biological process.

And now, having tried to obtain some insight into the physiological nature of the increased uric-acid output, we may return to the more practical question, What is the actual value, in practice, of our exact knowledge of the uric-acid output of our patients? In the first place, it appears to me that the value of this knowledge is quite different from what it is popularly supposed. It does not give us information about a particular morbid state or diathesis, but rather an indication of the existence of a defect in general nutrition with little or no information as to the nature of this defect, except that it can be induced, and is per-

haps generally induced, by the existence in the blood of a toxic substance formed during the process of digestion.

Now, this information, general as it is, has this value in practice: It gives us an objective basis for deciding whether the line of treatment that is being pursued is or is not effective. Thus, if I find that a patient has a habitual ratio of uric acid to urea of 1 to 25, I know from experience with such cases that he has a disturbance of nutrition from which it is doubtful if he will recover under any treatment, unless the disturbance from which he is suffering be an acute one. If I find the relative ratio to be 1 to 40 or 1 to 35 (on a mixed diet without alcohol), I consider that I have to deal with a distinct but not extreme excess of uric acid which will be lessened and perhaps entirely removed by treatment. Moreover, these results upon the uric-acid output, being very accurate, give us a criterion of judgment which we may employ separately from the symptoms themselves. Again, if a patient with excessive uric acid be put upon treatment calculated to remove the primary trouble and hence reduce the excess, an examination of the urine in two weeks from the beginning of treatment shows conclusively whether this treatment is having the desired effect or not. There is thus little delay in determining whether the treatment is or is not satisfactory. If the urine shows no improvement, it is conclusive evidence that the treatment is not effective and must be changed. There is another prognostic point which I should emphasize here. The fact that the uric acid returns to normal upon a careful diet does not necessarily show that the real trouble is removed or that the patient has recovered, for mere dieting will reduce the output very much. The crucial test is to put the patient on a reasonable mixed diet. If on such a diet the uric acid remains normal, we may assume that the nutritive disorder on which the excess depended has been improved. If, however, the uric acid runs up, we know that the improvement was only apparent and due merely to the continuance of a restricted diet. In conclusion, therefore, we may say that the chief value of determining uric acid in disease is the light it gives us upon prognosis and upon the intelligent conduct of treatment. Its value in diagnosis is much less, and has, I believe, been greatly exaggerated through the idea that uric-acid excess indicates a special condition. I have met with a few cases where uric acid was eliminated in excess without there being symptoms to correspond; but this is certainly rare, and, generally speaking, it is not very difficult to predict from the symptoms in what cases such excess is likely to be found. This fact leads me to think that a good deal too much importance is attached to obtaining an exact uric-acid method for the use of physicians. The number of cases where it is important to have exact knowledge of the uric-acid output does not appear to be very large, and it is hardly worth the effort of the physician to learn an exact method for occasional use. It is better, I think, to send the urine for examination to a reliable commercial chemist, who can do the Ludwig-Salkowski method, and report the results for the interpretation of the physician.

There is one aspect of the elimination of too much uric acid about which we have no knowledge whatever at the

present time, and that is the effect upon the kidney of habitually excreting this excess. There are those who see in the existence of general arterio-sclerosis and chronic diffuse nephritis evidence of the long-continued activity of some toxic substance in the blood, and it has been suggested and even affirmed that uric acid is this substance. It would certainly be interesting to follow the history of persons who habitually excrete too much uric acid, with an eye to renal sequelae; but it must be candidly owned that we have not very much reason to be suspicious of uric acid as a poison. So far as known, people who are very anæmic for a long period or very neurasthenic are not more liable to kidney disease than others, yet we know that they are among the most inveterate uric-acid offenders. While upon the most purely theoretical grounds it does not seem very likely that uric acid has much to do with chronic nephritis, it appears to me that an experimental research might with advantage be undertaken into the possible relation between uric acid and other nitrogenous extractives and the causation of chronic diffuse nephritis and its associations.

When we come to the question of treatment it becomes especially important to bear clearly in mind what I may call the central facts of this paper—that an increase of uric acid does not mean that the patient is suffering from the effects of an excessive quantity of uric acid in the blood; that he is suffering not from disturbance in the later stages of metabolism, but rather from some primary disturbance of which the exact nature is at present unknown in the earlier stages of assimilation and absorption, this disturbance (whether or not the same in all cases) being associated with a great variety of clinical manifestations. As a rule, there are more or less evident errors of digestion, and it is to these that treatment should be especially addressed, though as yet we do not know enough about the variations in the intimate nature of these primary disorders to enable us to individualize closely in our treatment. There are, however, certain facts of a hygienic nature that seem to be generally applicable. Diet stands first in order among such means. Speaking generally, a diet consisting chiefly of animal nitrogenous food is that which best suits most uric-acid offenders. My practice in prescribing a diet is this: An effort is made to "size up" the case as to gravity from previous experience, and a diet is ordered consisting chiefly of milk, red meat, green vegetables, and zwieback, starches and sugar being diminished or cut off according to the indications. It is best at first to make only a moderate reduction, if possible, in the carbohydrates. If at the end of two weeks the uric-acid ratio is found to lie in the neighborhood of 1 to 50, the diet is considered satisfactory, and as much carbohydrate food is added, in the form of rice, hominy, and potatoes, as is consistent with keeping the ratio in this vicinity. It is a very easy matter to simply reduce the uric-acid ratio without any regard for other considerations; you can do it by putting your patient on a milk diet or on a Salisbury diet. But it is usually a mistake to do this without regard for the weight of the patient, which is greatly reduced by such a course and which it becomes exceedingly difficult to restore. I believe that the wisest plan is to keep patients on a mixed diet, in

which all classes of food are represented, and to allow just as much starchy food as is consistent with the avoidance of a uric-acid excess. I believe there are persons who consider the use of red meat injurious in these cases and who prefer to put their patients on a wholly or largely vegetable diet. I have never had the hardihood to order a vegetable diet for purposes of treatment, but I have used such a diet for experimental purposes and found that there was induced not only intestinal disturbances but a higher uric-acid ratio than had been present when a mixed diet with free use of meat was allowed. Another point in regard to diet is the avoidance of an excess of nitrogenous food. Because an animal nitrogenous food is well borne, we are not justified in pushing it to excess, as is often done with a view to "building up" patients. Such an excess may be borne for a time and even appear to do good, but after a while it gives rise to digestive disturbances. A good rule is not to let the amount of urea excreted go beyond, say, one gramme in the twenty-four hours to five pounds' weight of the patient. Thus a person weighing a hundred and fifty pounds would be allowed to excrete in the neighborhood of thirty grammes of urea daily, while a person weighing a hundred pounds would be allowed to run as high as twenty grammes. In this calculation the weight is considered as undergoing little alteration.

The influence of overfatigue is, I believe, very great in bringing about the primary disorder of absorption which leads to uric-acid excess. I have repeatedly had the experience of seeing a uric acid run up in consequence of physical overexertion while a restricted diet was being rigidly adhered to, and can not but feel that the avoidance of such excessive fatigue is one of the most important things in the treatment of these cases. The endurance of these patients is not usually great and each has to learn for himself how much and how little he may safely do. There are many persons whose daily duties, though of a sedentary nature, are largely fatiguing and who become further exhausted by active exercise. It is in cases of this sort that massage has seemed to me to be particularly beneficial in developing the power of resistance to fatigue. In some cases, where exercise was at first impracticable, endurance was so increased after a few weeks of massage that active exercise in walking could be recommenced without fatigue. It has seemed to me that in business men the effects of massage have been distinctly better when the treatment was applied in the morning before business than in the afternoon or evening.

Of treatment by drugs I have little to say, as such treatment appears to me quite secondary in importance to more purely hygienic measures. But while treatment by drugs is of secondary influence it should not be overlooked, for it may be a real help. Of all drugs, arsenic appears to be the most valuable in aiding nutrition to overcome the disturbances which result in uric-acid excess. How it acts is not really clear, but there is no doubt in my mind of its ability to modify nutrition in such a way as to reduce an excessive output of uric acid. The most striking proof of this I have met in cases of chorea, in which the symptoms and the associated large excess in uric acid have been proportionately

controlled by arsenic. Where anæmia exists it is well to give iron and arsenic alternately.

A good deal has been said about the use of drugs that are supposed to "wash the uric acid out of the system." Alkaline waters, lithia water, and of late piperazine water have been recommended for this purpose. When we reflect that uric acid is eliminated with great rapidity as soon as it gets in the blood, and that it is itself no poison, it is difficult to see how we can do good by attempts to eliminate it. The trouble is at the other end of the process, and we should try to check uric-acid formation instead of resorting to the ridiculous attempt to eliminate what does no harm and eliminates itself. The "washing-out" treatment always reminds me of the good woman whose child was run over, but who was greatly consoled by the thought that the brute of a driver had been arrested. The damage is done, and the deed is a thing of the past when the excess of uric acid gets into the blood; there is not even the motive of revenge for trying to eliminate it. Then, again, it is extremely doubtful whether these lauded drugs really do "eliminate." I can not make any positive statement about lithia, but I have experimented with piperazine on normal and abnormal persons and have satisfied myself that it has very little effect on uric-acid excretion. A trivial increase in uric acid was indeed noted, but this was attributable to the slight disorders of digestion induced. In a considerable number of the persons who excrete too much uric acid the urine is scanty and of high specific gravity, and the free use of water helps to restore the proper volume and density of the urine. It seems more than probable that the various mineral waters recommended for the so-called uric-acid diathesis do good as diuretics rather than through any influence upon the formation or elimination of uric acid. I may take this occasion to say that while piperazine has no appreciable effect upon uric-acid formation or elimination, it has seemed in one case of gravel to reduce very much the size of the calculi passed and to diminish the frequency of the attacks.

To conclude, it appears to me that we have been attaching a false significance to uric acid in its relation to disease. The view that uric acid is in any sense a factor in disease, except in a purely mechanical way, is, I believe, destined to die out wholly. We have been attributing to the ash the qualities of the flame.

The Medical Society of New Jersey held its one hundred and twenty-seventh annual meeting in Asbury Park on Tuesday and Wednesday, June 27th and 28th, under the presidency of Dr. George T. Welch, of Passaic. The programme included the following titles: Bovine Tuberculosis—its Transmission to Man, and how to Prevent it, by Dr. J. W. Stickler; the president's annual address, on Therapeutical Superstition; Legislation for the Prevention of Blindness, by Dr. W. B. Johnson; a discussion of the question Is the Philosophical Practice of Medicine not materially Jeopardized by the Modern Methods of Venders of Drugs? (to be opened by Dr. H. L. Coit); An Investigation as to the Use of Magnesium Sulphate hypodermically administered, by Dr. J. Percy Wade, a corresponding delegate from Maryland; The Quarantine of Cholera, by Dr. William Elmer, Jr.; and Some Thoughts on Symptoms and Diagnosis, by Dr. S. E. Armstrong.

The American Electro-therapeutic Association.—The third annual meeting will be held in Chicago on September 12th, 13th, and 14th.

A FURTHER CONTRIBUTION TO THE SUBJECT OF "ANIMAL EXTRACTS."

BY WILLIAM A. HAMMOND, M. D.,
SURGEON GENERAL, U. S. ARMY (RETIRED LIST).

FROM several communications that I have received from physicians who are engaged in extracting cerebrine according to my formula, I learned that they have taken special pains to get rid of the blood contained in the cerebral vessels, especially of that in the sinuses. This is all wrong, as to the intracranial blood is to be attributed, in my opinion, much of the physiological and therapeutical effect of the cerebrine. In the experiments performed several years ago by myself and others relative to the juice of the testicles, it was always found highly desirable not to remove the blood from the organs. In my published communications I have stated that the brain is to be carefully washed in a solution of boric acid, and this procedure is solely for the purpose of getting rid of all extraneous matter that might have come in contact with it after its removal from the skull and before it reached my laboratory. In the absence of any express direction to remove the blood, I took it for granted that such a course would not be adopted. To this fact, and to the additional one of endeavoring to extract in a few days a substance that can not be obtained till after the lapse of several months—six at least, and twelve are better—must be ascribed the failure of a certain drug firm, who, without my knowledge or consent, chose to go into the business of manufacturing cerebrine for sale, to get anything but an entirely inert product—one, in fact, that can be taken in ounce doses without any other effect than would be obtained from a like quantity of a mixture of alcohol, glycerin, and a solution of boric acid.

It is well known that in old specimens of brain and other nervous tissue preserved in alcohol a substance crystallizes out and is deposited upon the surface of the specimens. This has received the name of "spermine." It is only after several months and sometimes years that it makes its appearance. Chemical analyses now being conducted, but not completed, show that spermine is a constituent, though not the only one, of cerebrine and in greater or smaller proportion of the other animal extracts—medulline, testine, ovarine, cardine, and musciline—made by my processes. Undoubtedly its presence is due to the fact that the organs subjected to extraction contain a large amount of nerve tissue. Pure spermine,* with which I have experimented to a large extent, acts in some respects, so far at least as the immediate effects are concerned, like cerebrine. It produces a similar vaso-motor disturbance, but not to as great a degree in corresponding doses. It certainly is not the only active principle of cerebrine or of the other animal extracts. I have not been able to ascertain that spermine produces any decided permanent effect upon the organism, though I have taken it myself in double and treble doses and given it to others to a like extent for several weeks at a time.

Whether, as I stated in my original communication, the essential factor of cerebrine is a substance pre-existing in the brain tissue and extracted by the menstruum or is a secondary product I do not know, nor, so far as its therapeutical properties are concerned, is it a matter of much importance. It is something which I know to be curative of certain morbid cerebral conditions, but whose thorough study is by no means yet accomplished.

The immediate effects of the cerebrine and of most of the other extracts are those indicating vaso-motor disturbance, and are so far similar to those produced by the nitrite of amyl and trinitrin or nitroglycerin. It is of much longer duration, but not so intense as that produced in the average person by a drop of a one-per-cent. solution of nitroglycerin. I have experimented largely upon myself and others with fresh extracts of the brain mixed with solutions of nitroglycerin of various strengths, and I am convinced of the great difference in the action of these mixtures and of cerebrine prepared according to my formula. It has been observed by those who have employed the extract of the thyroid gland in the treatment of myxœdema that even more severe symptoms usually follow the administration. These are in the form of giddiness, headache, faintness, and an apparent tendency to convulsions, and occasionally it has been found necessary to suspend the treatment on this account. Similar effects to those produced by cerebrine are generally observed from the hypodermic injection of the extract of nerve substance prepared by Dr. Gibier. I have never in a single instance—and I have used them many hundreds of times—observed the slightest alarming effect from the use of the animal extracts prepared according to my method.

I have sometimes thought that the combination of glycerin, alcohol, and the highly nitrogenous substances from which these extracts are made might result in the production of a substance analogous to nitroglycerin, and in my first communication on the subject to the *New York Medical Journal* I threw out the suggestion of a secondary product being formed. As I have said, however, the thorough chemical analysis which is now being made will, I hope, dissipate the uncertainty which necessarily exists relative to the exact composition of these extracts.

A word as to one of the critics of my facts and theories. So far as the latter are concerned, I have not the slightest disposition to say a word or commit an act that may impede the fullest expression of opinion. But I think the discussion should be conducted in a decorous manner and that my sincerity of statement should not be impugned. I am therefore surprised to find that Dr. J. S. Leonhardt, who is evidently a physician with a scientific training, should, in the number of this journal for June 10th, adopt a sarcastic tone in regard to the theory and one of incredulity relative to the facts. I think my contributions to this subject have been written with moderation and frankness. I have deprecated extravagance, have held nothing back, and have claimed little, leaving it to the experience of the profession at large to determine the true value of the animal extracts that have formed the subjects of my studies. I am aware of all the difficulties connected with such an

* Manufactured by Messrs. Clinton E. Worden & Co., San Francisco, California.

investigation; but having been one of the first, if not the very first, in this country to enter upon the practical study of experimental physiology and physiological chemistry, having held a professorship of those branches in a prominent medical college, and having continued to work in them to the present time, I consider myself quite as competent to form an opinion on any point connected with those sciences as is Dr. Leonhardt.

In regard to the sphygmograms printed with my paper on Cardine I have only to say that they were made with Marey's sphygmograph, and are engraved from accurate pencil tracings made on the blackened paper of the apparatus. Every one who uses the sphygmograph will know how impossible it would be to send by mail from Washington to New York the original sphygmograms without the great risk of having them obliterated or seriously damaged before they reached the engraver. As regards their value, that is a matter of opinion, and Dr. Leonhardt has a perfect right to estimate them according to his own notions. Their authenticity, however, is quite another matter, and if he questions that, I have only to say that he commits a solecism against good manners for which it would be difficult to find an excuse. It is true, I can not boast of having "several thousand sphygmograms" in my possession, but I have been accustomed to the use of Marey's and Poud's sphygmographs, the one for over thirty and the latter for more than twenty years.

Dr. Leonhardt apparently ignores the fact that the tracings made by one kind of sphygmograph can not be compared with those made by a different instrument. Doubtless "Dudgeon's" sphygmograph—with which, however, I am not acquainted—is entirely competent to be used in the determination of the action of cardine upon the heart, but until Dr. Leonhardt ceases to theorize from the tracings of my sphygmograph to those of the one he is accustomed to he is not in a position to give a logical opinion on the subject.

Let him therefore experiment with "Dudgeon's" sphygmograph as I have done with Marey's, and then, though doubtless the tracings will be different from mine, he will at any rate be competent to judge so far as his own instrument is concerned.

In point of fact, however, he admits that the sphygmograms printed in my paper teach to some extent exactly what I say they do—namely, that cardine increases the frequency and tension of the pulse, but he denies that they show increase of the force. I say they do, inasmuch as the up-stroke of No. 2 and No. 3 is less vertical—more oblique—than that of No. 1.

When Dr. Leonhardt, from the examination of tracings not made with an instrument with which he is working and with whose rate of movement he is unacquainted, undertakes, as he does in his criticism of tracing No. 2, to state the frequency of the pulse, he does that which every experienced sphygmographist knows can not be done with even an approach to accuracy. The length of the line between any two up-strokes depends on the velocity of the paper moved by the clockwork, and is rarely, if ever, the same in any two instruments of different makers or even in

any two of the same kind. It is by this line that the frequency of the pulse is measured. When the paper moves rapidly the line is short, when it moves slowly the line is long. All that Dr. Leonhardt or any one else can say from a comparison of tracing No. 1 with tracing No. 2, so far as frequency is concerned, is that No. 2 indicates a more rapid pulse than does No. 1. The pulse making the tracing No. 1 was 68, of No. 2, 85, and of No. 3, 74, and I am able to state with absolute positiveness that the subject has no cardiac or arterial disease, notwithstanding Dr. Leonhardt's opinion to the contrary.

As to Dr. Leonhardt never having seen any similar sphygmographic tracings, I can well believe his assertion; but if he will kindly take the trouble to consult Marey's *Physiologie médicale de la circulation du sang*, Paris, 1863, he will find not "several thousand" perhaps, but enough, I think, to convince him that there is even yet something for him to learn on the subject.

ON A NEW AND IMPROVED ASPIRATOR AND INJECTOR.

By J. J. HIGGINS, A. M., M. D.

OF the value of aspiration for diagnosis, or treatment by the evacuation of fluids, it is needless to speak. Its introduction into medical practice by Dieulafoy in 1869 was at once followed by universal acceptance. For its performance a suitable apparatus by means of which a vacuum as perfect as possible can be created and maintained is the essential point. Success, either for the verification of diagnosis or in treatment, is dependent upon this exhaust power being present, but in the various apparatuses made, failure in its production is more common than otherwise. The instrument may indeed at the moment of purchase seem satisfactory, but when, after no great lapse of time, it is wanted or again used, it fails, and either we are convinced (ofttimes against our best judgment) that our diagnosis is wrong, or feel that aspiration is not what it is claimed to be. Such very general defect is not, as sometimes told us by the makers, inherent in the instrument, but due entirely to faulty construction. First, in that the valves in the exhaust pump are miserable apologies for the same and out and out worthless. A slip of either rubber or leather tied over an opening constitutes this all-important part. With the very first withdrawal of air through the opening the valve, if of leather, is bulged up to allow of its passage, and now, on suction ensuing, is no longer a flat surface, and leakage results; if of rubber, it is merely a matter of a short time, especially when in contact with oil, before disintegration takes place, and now, with its elasticity gone, it also no longer serves its purpose. For the physician to be compelled every time he wishes to use the instrument to take it apart, and removing the old valves replace them with new ones, is decidedly objectionable. It is a task neither clean nor inviting and that should not be necessary—and in a perfectly made instrument is not. In the new and improved aspirator made by Messrs. George Tiemann & Co. from designs and models furnished them by me, we have a valve that is perfect: as

perfect, it matters not how long it may have been since it was used, nor how often, as at first—a valve that is a true valve, that can not get out of order and is always operative. It is patterned after those used in the construction of the costly air pumps employed in the scientific lecture rooms and laboratory, with, however, very material improvement.

Again, the contention that air-tight closure of the exhaust bottle can be effected by a cork, even if of rubber, is sheer nonsense. The usual opening of the bottle is about an inch and a half in diameter, necessitated by the cork having to be large enough for the transmission of two or more tubes. When exhaust is made, no reliance can be placed upon the air-tight closure of such a sized orifice by corking it. In a short time, even if momentarily secure, which is doubtful, air will have permeated into the bottle and suction be gone. In one way only can this for a surety be effected, and that is by the making of such jointure through the medium of a metallic cap hermetically sealed upon the bottle, to which with its intermediate washer the pump is screwed. And here even an opening of such large size would be seriously prejudicial. In the present instrument—and it is the only one so made—such mode of attachment is made use of, and I have so devised and simplified its construction that only an opening of half an inch is required for the passage of the tubes, and a perfectly and absolutely air-tight junction is readily effected. So much so is this the case that the bottle after exhaustion can be put aside for days, and on examination found to be still the same container of nothing that it was at first. The pump is of hard rubber, it being altogether preferable to metal, and of greater capacity than usual. The distal end connecting by screw thread with exhaust bottle is, however, of metal, as being here most suitable. The tube connections are all made by screw and not by permanent affixture, in order that they may be separated at will for cleaning or laying away. The needles are each stamped with figures stating their size, and have a flattened surface upon their haft indicating the cutting side. All faucets are of the kind called stop faucets, and the container or exhaust bottle is graduated by ounces up to one pint. In a word, nothing is wanting that care and oversight, regardless of trouble and expense, could suggest for the construction of a perfect—in fact, model—aspirator. But were this all that was done it would still leave an imperfect instrument, for up to date none have been made that are not so. Each and every one in the market is lacking and deficient, and, as will be seen, most radically so. For by what means or whereby is the certainty of the existence of the necessary vacuum made known, or information given of its dissipation and consequent necessity of its renewal? None whatever. A few pulls of the pump and it has to be taken for granted that the required vacuum exists and continues to be present. But the taking of a thing for granted is a mighty poor basis for any one—much more the physician—to make procedure on. Such incertitude should not exist, for with the absence of a vacuum not only is aspiration, upon which the patient's welfare is dependent, impossible, but, relying upon the presence of that which is not, the practitioner is misled, or made doubtful as to the correctness of his diagnosis.

To secure this very necessary end, an attachment termed

a "vacuum gauge" would be needed, but its bulk and cumbersome nature have been so against it that, however greatly to be deplored, it has universally been omitted. In the aspirator now introduced to the notice of the profession this long-felt want is supplied without additional bulk or complication by the most simple of simple methods. By merely the interposition of a small bulb (see cut) of proper ri-

- A. Arms for air-tight closure.
- B. Vacuum Bottle or Container.
- C. Metallic Hermetically Sealed Cap.
- M. Milled Head for ready separation of Tubing.

gidity on the exhaust tube all is happily effected. If a vacuum is present it will collapse, and more or less so in exact ratio with the amount of exhaust, and the operator sees at a glance the condition of his instrument, not only when commencing, but also during aspiration. As the withdrawal of fluid proceeds and the completeness of the vacuum consequently lessens, the bulb shows it at once, and further exhaustion as indicated can be made. How vital, how all-important it is that such an addendum should always be an integral part of every instrument can not be too highly accentuated, as may be seen from the case of a gentleman to whom one of our most distinguished surgeons of this city was called, and who after careful examination diagnosed the case as one of lumbar abscess and proposed and performed aspiration with, however, a negative result.

Two days afterward I was summoned to the case, and, making the same diagnosis, similarly proposed aspiration. I was then told of the agreement in diagnosis of myself with the previous surgeon and of the operation and its failure to support such opinion. By strenuous insistence, however, I was permitted to operate and did so in exactly the same place—same direction and length of introduction of needle—as far as could be determined, and drew off a quart and a pint of pus.

Now, it will hardly be maintained that in two days this amount of matter could have formed. What, then, was

the reason of the operation in the one case being a failure and in the other a success? Simply, undoubtedly, in that the exhaust and consequent suction power in the instrument used (known as Dieulafoy's) was wanting, whereas in mine it was present, and *not thought but known* to be so. Here a worthless instrument imperiled a patient's life (for entire recovery took place), and, moreover, caused a most experienced surgeon to be at a loss as to the nature of a disease of which he had really made a correct diagnosis. The biblical text "to prove all things" is especially commendable in the use of aspirators. Again, a further improvement in aspirators demands an arrangement whereby, after aspiration, injection into the cavity of an antiseptic or medicated fluid can be made and then reaspirated therefrom. Not only by this means may direct curative application be utilized, but, by repetition, thorough washing out accomplished. In the construction of the present instrument this feature has received careful attention, and injection as well as aspiration can at will be performed *without either change of needle or admission of the least particle of air*.

Although, as previously remarked, of the value of aspiration and the many cases to which it is applicable it is needless to speak, yet the following extract from the *Lancet* (Paris correspondent), April 18, 1891, page 907, may be of interest as showing a still larger field for its employment than that to which originally it was thought adapted:

"The treatment of chronic or cold abscess by the method of aspiration and injection of antiseptic solutions, such as iodoform dissolved in ether, is a favorite plan of some French surgeons and is the one usually adopted for some time past in the wards of M. Verneuil, now senior professor of clinical surgery in the Paris faculty. But it appears to have been reserved in the country to Dr. Piechand, of Bordeaux, to have adapted the method with success to the treatment of acute inflammatory abscesses. Instead of the time-honored free incision of the most dependent part, Dr. Piechand aspirates the abscess, after which he injects a solution of 1 to 1,000 of corrosive sublimate. For the past ten months he has invariably adopted this method in his hospital practice and, he declares, with marked success.

"Even if the skin over the seat of the abscess be thinned and undermined, this is no bar to the procedure, for which he claims as advantages that it is less painful, leads to more rapid healing, and leaves no trace of scar."

In corroboration of the foregoing I would state that quite a number of cases so treated by myself have, by the success attendant, proved it to be of great merit.

NO. 23 BEEKMAN PLACE.

The American Association of Genito-urinary Surgeons has elected officers for the ensuing year as follows: President, Dr. George Chismore, of San Francisco; vice-president, Dr. L. Bolton Bangs, of New York; secretary and treasurer, Dr. John A. Fordyce, of New York; member of the council at large, Dr. Robert W. Taylor, of New York.

Yale University.—The annual address in medicine was delivered on Tuesday, June 27th, by Dr. Henry P. Walcott, of Cambridge, Mass., on The Profession, the Colleges, and the Commonwealth. In the evening a reception was held in Dr. Walcott's honor at the residence of Professor William H. Carmalt.

THE NEW YORK MEDICAL JOURNAL,

A Weekly Review of Medicine.

Published by
D. APPLETON & Co.

Edited by
FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, JULY 1, 1893.

THE CITY BOARD OF HEALTH'S AID IN THE DIAGNOSIS OF DIPHTHERIA.

A CIRCULAR recently issued by the Board of Health of the Health Department of the City of New York, published in this issue of the *Journal*, seems worthy of more than ordinary attention, not only for the immense assistance that the work it announces the board's readiness to undertake promises to render to the medical practitioners of the city, but also, and chiefly, as heralding the assumption of what appears to be a new function in boards of health—that of giving to the individual physician the aid of resources ordinarily beyond his reach and far more acceptable to him than an inspector's visit to his patient. To fight against the introduction and spread of infectious diseases, and incidentally to aid in the diagnosis by sending an officer supposed to be possessed of special experimental knowledge of certain forms of disease, have always figured prominently among the duties undertaken by our board and, it is to be presumed, by other boards of health; but this, so far as we know, is the first instance in which a board of health has announced its readiness to facilitate physicians' practical daily work in any other way than by its own appearance on the scene in the shape of an official sent to represent it.

What the New York city board now undertakes to do, as will be seen by the circular, is to make bacteriological examinations in cases of diphtheria and of throat affections so closely counterfeiting that serious disease as to prove puzzling to the physician and embarrassing to the household in which they may appear. All the family physician has to do is to remove from the affected surface, by means of a cotton swab, material which he is to place on a culture medium provided by the board, and send it to any one of a large number of conveniently situated designated depositories, one of which is the board's own laboratory; within twenty-four hours, and earlier, by telephone, if need be, he is informed of the result of the board's bacteriological examination—that is to say, of data on which he may found a positive diagnosis at a comparative early period in the progress of the case. What trouble may thus be averted in cases of real diphtheria by enforcing the patient's seclusion and other necessary precautions, or, in cases that only simulate diphtheria, what needless alarm as to the result to the individual and what uncalled-for abstention of other members of the family from attendance upon him and from free association with others, will at once come to the mind of every family practitioner. In view of the well-known skill of the board's bacteriologists, it is to be taken for granted that the light swabbing specified in the circular is considered sufficient for

the purpose; they are not the men to take upon themselves the responsibility of declaring a diagnosis—for practically that is what their report amounts to—without all the necessary data attainable.

For this undertaking, as well as for many of its recent enterprises, the city board of health seems to us to deserve high commendation. We see no reason to doubt that the plan set forth in its circular will work satisfactorily, and we hope to see it applied in cases of other diseases and its use extended to other communities than our own.

THE MEDICAL CORPS OF THE ARMY.

It is reported that Surgeon-General Sternberg, with the approval of the Secretary of War, has planned courses of special instruction for newly appointed medical officers of the army, to be given in the Army Medical Museum. The instruction is to be to a certain extent what a post-graduation course in medicine would naturally be expected to be—that is, more or less in continuation of the studies pursued by medical students before receiving the degree—but in some respects it will probably be virtually in new studies, for even in the best of our schools some branches of learning that are closely allied to medical knowledge are so lightly touched upon that they are practically a terra incognita to the young medical graduate. But, besides supplementing the youthful assistant surgeon's strictly professional education, the courses contemplated will include one upon the business affairs of a military medical officer's daily life, such as his relations to the soldiers and their families and to his fellow officers, both of his own corps and of the army in general, the customs and needs of the service in such matters as making out reports, and numerous other details the knowledge of which there has heretofore been no means for the young medical officer to acquire save by chance observation or by asking questions.

It is wonderful that in the absence of such a school the medical officers of our army so readily got the run of their duties and prerogatives during our last war, but much time could have been saved if it had been in existence. When the war was over and the army was reduced to the dimensions of a mere nucleus, it would probably have been difficult to find suitable quarters that the Government would have consented to put to such a purpose as that of giving special training to so small a body of men as the medical corps of the army, but now that we have the Army Medical Museum that obstacle seems to be done away with. There can, we think, be no reasonable doubt that the Army Medical School will prove to be a powerful factor in increasing the efficiency of the army medical service. Its design is exceedingly creditable to the new surgeon general, and he is to be credited also, we learn, with having resolved upon a most desirable change in the system of distributing his officers to stations; instead of continuing to send the young men to the plains to work their way up through tedious years of humdrum service to stations where there is something going on that is of interest to them, Surgeon-General Sternberg will

endeavor to give each of them a considerable period of service at a post where attendance at the great civil hospitals, the college laboratories, the medical libraries, and the meetings of medical societies may aid him in fitting himself for the second examination. While the opportunities of the older officers should not be curtailed, certainly those of the younger ones should be enlarged, and we know of no better way of accomplishing that end than the surgeon general's plan of stationing junior medical officers.

MINOR PARAGRAPHS.

MODIFICATIONS IN LEUCOCYTES IN INFECTION AND IMMUNITY.

In the *Annales de l'Institut Pasteur* for February 25th, Mlle. C. Everard, M. J. Demoor, and M. J. Massart publish an interesting study of the quantitative and qualitative variations in leucocytes during infection and immunity. Their experiments show that an injection of cultures containing living or dead microbes produces, in the first place, a diminution in the number of leucocytes in the circulation, especially of leucocytes having a compact polymorphous nucleus and granular protoplasm. When the animal resists the infection the period of hypoleucocytosis is followed by a brief time during which the variety of leucocytes above mentioned is very abundant; subsequently the blood resumes its normal character. This typical period of hyperleucocytosis is sometimes completely wanting in animals that succumb to infection, when death occurs rapidly, and sometimes it is replaced by a series of oscillations in the number of leucocytes when the infectious disease is prolonged for some time. The blood of an animal that has received a protective inoculation before the injection of the cultures of bacteria is richer in leucocytes than that of an ordinary animal. These observers believe that the various forms of leucocytes are stages in the evolution of the same cell, the young leucocyte having a single compact nucleus and a small quantity of protoplasm, and afterward becoming vesiculated and having the protoplasm increased; and that eventually the adult leucocyte, capable of exercising the function of a phagocyte, presents a compact polymorphous nucleus and has its protoplasm covered with granulations.

THE GERM THEORY AT THE BEGINNING OF THE EIGHTEENTH CENTURY.

ACCORDING to the *British Medical Journal* for June 10th, Dr. Reid read, at a recent meeting of the Halifax branch of the British Medical Association, the following extract from *A Treatise on Consumption of the Lungs*, by Edward Barry, M. D., London, MDCCXXVII: "In this treatise I have proposed rather to lay down a right account of this Distemper than to examine the errors of others; but, however, I cannot well avoid mentioning the author of a late hypothesis—Martin on *Consumption*, pages 50-51, which some may be more inclined to believe, since no less than *ocular demonstration* is offered to confirm the truth of it. This person takes notice that *ulcers* in the *lungs*, when narrowly viewed with microscopes, are covered with several *insects*, and from thence concludes that they take their first origin from such *animalcules*, which, being inspired with the air, fix their situation on the *lungs*, and erode and ulcerate the *vessels* . . . these *animalcules* have been by others supposed the causes of several distempers, and particularly such as are *contagious*. . . For it is certain that there is almost an infinite number and va-

riety of such *animalcules* perpetually floating in the air, whose chief business consists in searching out a place where they may find nourishment and a proper situation for themselves and their young." The Italics are in the original.

THE TREATMENT OF CHOLERA WITH ATROPINE.

At a recent meeting of the Royal Medical and Chirurgical Society of London Dr. Lauder Brunton stated that in 1873 he had called attention to the close resemblance between the symptoms of cholera and those of muscarine poisoning; and, as the latter could be relieved by the subcutaneous injection of atropine, had suggested that good results might be hoped for in cholera from administering atropine. He had not had an opportunity of acting on his theory until last year, when the atropine had proved very useful in treating two cases of cholera. It seems singular that one so well informed as Dr. Brunton should apparently be unaware that this suggestion had been made and successfully carried out years before he made it. We need not refer to the facts that Viardin in 1882 (*Gazette médicale de Paris*, 1882, p. 810) and Chalvet in 1859 (*Gazette des hôpitaux*, 1859, p. 473) successfully employed belladonna in the treatment of cholera. But in 1866 the late Dr. John T. Hodgen, of St. Louis, published an article (*St. Louis Medical and Surgical Journal*, 1866, p. 497) advocating the administration of atropine to relieve the collapse of cholera, and for years afterward in his lectures he referred to the usefulness of this drug. In the cholera epidemic of 1873 a number of American physicians employed atropine in treating cholera.

PROFESSORS' SALARIES IN SCOTCH UNIVERSITIES.

The *British Medical Journal* for June 17th states that in the University of Edinburgh the salary of the professor of anatomy is sixteen hundred pounds, and that those of the professors of physiology, chemistry, and pathology are fourteen hundred pounds each, of those of natural history, botany, and materia medica, a thousand pounds each, of those of medicine and of surgery nine hundred pounds each, and of those of midwifery, clinical surgery, and forensic medicine, eight hundred pounds each. The professors of anatomy, physiology, chemistry, pathology, natural history, and botany are not to engage in private practice. Additional fees allowed all these professors further increase these incomes. At the smaller University of Aberdeen the professor of anatomy receives eleven hundred pounds; the professors of chemistry, of physiology, and of pathology, nine hundred pounds each; those of natural history, of materia medica, and of botany, seven hundred pounds each; and those of medicine, surgery, forensic medicine, and midwifery, six hundred pounds each. These emoluments surpass those of most American medical colleges, if the purchasing power of the money is considered.

THE SUPPRESSION OF INFORMATION ABOUT CHOLERA IN FRANCE.

SERGEON FAIRFAX IRWIN, of the United States Marine Hospital Service, reported in the *Abstract of Sanitary Reports* for June 16th that the authorities of Marseilles had not only refused him the opportunity of inspecting the records, but suppressed everything relating to cholera, and that the newspapers were not permitted to publish the causes of deaths. The *Medical Week* for June 16th independently corroborates this report, stating that both the local and the central authorities seem once more to be endeavoring to conceal the truth, or at any rate to

hide it under all sorts of designations. A rapidly fatal diarrhoeal disease has appeared in a number of the maritime departments of France, but not a single systematic bacteriological examination has been made. This course of concealment and perversion is in direct conflict with the agreement made at the recent sanitary conference at Dresden, and, though the agreement has not yet been ratified, it has been accepted by the various signatory powers, one of which was France. Perhaps if our health authorities declared France infected with cholera, the local authorities would realize their duty.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

We are informed that the statement contained in our report of the proceedings of the recent meeting of the American Medical Association to the effect that Dr. Culbertson had been re-elected editor of the association's *Journal* was incorrect, and that Dr. John B. Hamilton, of the Marine-Hospital Service, was chosen. Dr. Hamilton's previous editorial connections and his well-known literary ability are full of promise for the future character of the *Journal*. The retiring editor, Dr. Culbertson, has done much to improve the publication, and Dr. Hamilton may be trusted to carry the process of improvement farther.

ITEMS, ETC.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending June 27, 1893:

DISEASES.	Week ending June 20.		Week ending June 27.	
	Cases.	Deaths.	Cases.	Deaths.
Typhus	3	4	6	2
Typhoid fever	12	4	19	6
Scarlet fever	139	14	66	12
Cerebro-spinal meningitis	10	7	4	2
Measles	182	9	214	15
Diphtheria	127	41	101	37
Small-pox	8	2	8	1

The Pan-American Medical Congress.—Section in Gynecology and Abdominal Surgery.—We have been asked to publish the following circular:

"All members of the medical profession are cordially invited to attend the meetings of this section to be held in Washington, September 5th, 6th, 7th, and 8th.

"The sessions promise to be exceptionally interesting, many valuable papers having been contributed. Those who may wish to read papers before this section and who have not yet sent in their titles and skeleton abstracts are requested to do so at once.

"Papers have already been contributed by the following distinguished gentlemen from the United States and Canada: Drs. T. Johnson Alloway, Montreal, Can.; A. W. Abbott, Minneapolis, Minn.; J. M. Baldy, Philadelphia, Pa.; H. J. Boldt, New York city; Augustus P. Clarke, Cambridge, Mass.; Ernest W. Cushing, Boston, Mass.; Andrew F. Currier, New York city; L. H. Dunning, Indianapolis, Ind.; George R. Deane, Spartansburg, S. C.; W. E. B. Davis, Birmingham, Ala.; Joseph Eastman, Indianapolis, Ind.; George M. Edebohl, New York city; De Saussure Ford, Augusta, Ga.; William Gardner, Montreal, Can.; T. H. Hawkins, Denver, Col.; John R. Haynes, Los Angeles, Cal.; Edward W. Jenks, Detroit, Mich.; Joseph Taber Johnson, Washington, D. C.; Howard A. Kelly, Baltimore, Md.; Florian Krug, New York city; G. Betton Massey, Philadelphia, Pa.; Lewis S. McMurtry, Louisville, Ky.; R. B. Maury, Memphis, Tenn.; William F. Myers, Fort Wayne, Ind.; E. E. Montgomery, Philadelphia, Pa.; Robert T. Morris, New York city; Charles P. Noble, Philadelphia, Pa.; Joseph Price, Philadelphia, Pa.; George H. Rohé, Baltimore, Md.; James F. W.

Ross, Toronto, Can.; Charles A. L. Reed, Cincinnati, O.; I. S. Stone, Washington, D. C.; R. Stansbury Sutton, Pittsburgh, Pa.; T. Algernon Temple, Toronto, Can.; A. Vander Veer, Albany, N. Y.; W. B. Ward, Topeka, Kan."

[Signed.]

W. W. POTTER, *executive president.*

BROOKS H. WELLS,

71 West Forty-fifth Street, N. Y. city,
English-speaking secretary.

The late Dr. James McCann, of Pittsburgh, Pa.—A committee of the faculty of the Western Pennsylvania Medical College has prepared the following memorial:

"James McCann, M. D., LL. D., was born fifty-seven years ago in Penn township, Allegheny County, Pa. His father served under Anthony Wayne in the war for American independence. In early boyhood he passed his summers working upon his father's farm, and the winter months as a pupil of John G. Beatty, who taught him, in addition to the public-school curriculum of that time, Latin and the higher mathematics. At about thirteen years of age his father died, when he began teaching school, and became a leading member of a local debating society. Even at this early date he was a ready, fluent, and earnest talker. Tiring of the monotony of country life, and, like the majority of young men of his age, not knowing exactly what to do with himself, he decided upon a mercantile career, and at the age of eighteen came to Pittsburgh, where, after graduating at Duff's College, he spent several years as bookkeeper in a business house. This sedentary life became irksome to him, his health was not good, and acting upon the advice of his physician, who regarded him as a young man of promising talents, he finally decided to study medicine. With this object in view, he in 1858 entered the office of Dr. Thomas and Dr. John Dickson, Sr.

"He graduated from the Medical Department of the University of Pennsylvania in 1863 and immediately entered the medical service of the army as assistant surgeon of the Fifth Pennsylvania Volunteers. He continued in this service until the close of the war, when he returned to Pittsburgh and began the practice of medicine with Dr. W. C. Reiter. Two years later he received the appointment of surgeon to the Marine Hospital and the connection with Dr. Reiter was soon afterward dissolved.

"He was next appointed one of the surgeons of the Western Pennsylvania Hospital, which position he held until a few months ago, when he resigned because of ill health, and accepted the appointment of consulting surgeon. For twenty years he has been one of the surgeons of the Pennsylvania, the Allegheny Valley, and other railroads entering this city.

"He was an active and influential member of the Pittsburgh Free Dispensary from its inception, of the board of health for many years, of the Allegheny County Medical Society, of the State Medical Society, of the American Medical Association, of the American Surgical Association, and of the American Association of Obstetricians and Gynecologists, but owing to ill health he was never able to attend a session of the latter.

"In spite of the busy life he led, his ardent love and natural aptitude for teaching led him—in connection with his confrères of the Mott Medical Club—to undertake the arduous task of organizing the first medical college in Western Pennsylvania. Into this work he threw all his enthusiasm, and devoted to it all his energy and influence. Caring but little for pecuniary reward, it was with him a labor of love. In September, 1886, after years of weary and distasteful work, the culminating point of his ambition was attained by his election to the chair of professor of the principles and practice of surgery. This position, notwithstanding his failing health and in defiance of bodily suffering, he filled until a few months prior to his death. At last, his physical endurance being exhausted, his grateful and sorrowing colleagues unanimously nominated him for appointment as emeritus professor, a last tribute to his eminent worth and ability; but before this action could be confirmed by the board of trustees of the university Death had claimed him as his own.

"He died a martyr to his profession—a sacrifice upon the altar of charity. His love for it and devotion to it was the direct cause of his death. He performed an enormous amount of work, and it was in the

performance of a surgical operation, a work of charity in the Western Pennsylvania Hospital, that he received the fatal shaft from the quiver of the fell destroyer. Had he, like many others, turned aside from charity work and devoted himself strictly to his lucrative clientèle, he would be living to-day.

"He never ceased to be a student. He was too broad-minded to make a successful specialist. His mental attainments were too great, his studies and reading too comprehensive, his ambition too high for any single department of his profession to permit free scope to his talents. His mind was alert to grasp and tenacious to retain knowledge, which enabled him to easily keep pace with progress and improvement, however rapid, in every department of medical science.

"He stood in the front rank of the leaders of the profession. His *savoir faire*, his strong personal individuality, his impulsive and generous nature, won him a host of friends in and out of the profession.

"His reputation and practice were not limited to his own city, county, or State, but were national. His life was one of unceasing toil. There are but few surgical operations that he had not performed. His profound knowledge, rather than his personal magnetism, made him popular with all the members of the profession with whom he came in contact, making him eagerly sought as a consultant, and he never betrayed this trust.

"He followed, as strictly as the present state of society will perhaps admit, the axiom, 'A physician's first duty is to his patient, his second only to himself.'

"He was in the active practice of his profession from 1863 to 1893—a period of but thirty years, yet in those thirty years he accomplished, perhaps, a task as great, and fulfilled a destiny as rounded and complete as the average practitioner of fifty years' standing. A man's life is measured by his works. Judged from this standpoint, although he was but fifty-seven years of age, his death was not premature.

"He had faults, but no vices, and his virtues were too many to dwell upon at greater length. By his death his wife loses a loving husband, his children an affectionate father, his colleagues a genial companion and true friend, and his profession a devoted follower. *Requiescat in pace.*"

[Signed.]

{ W. SNIVELY,
J. B. MURDOCK,
C. B. KING.

The Richmond Academy of Medicine and Surgery.—The special order for the last meeting, on Tuesday evening, June 27th, was the reading of a paper on *Placenta Prævia* by Dr. Mark W. Peyser.

Army Intelligence.—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from June 18 to June 24, 1893:*

An army retiring board having found SKINNER, JOHN O., Major and Surgeon, incapacitated for active service, the extension of leave of absence on surgeon's certificate of disability is further extended until further orders.

BROOKE, BENJAMIN, First Lieutenant and Assistant Surgeon, is granted leave of absence for two months, to take effect on or about July 15, 1893.

WOODRUFF, CHARLES E., Captain and Assistant Surgeon, is granted leave of absence for one month and twelve days from August 1, 1893.

HALLUCK, HARRY M., First Lieutenant and Assistant Surgeon, will, on July 6, 1893, proceed to Griffin, Ga., and report to Captain George G. Greenough, Fourth Artillery, for duty in connection with the encampment of State troops at that place.

GLENNAN, J. D., First Lieutenant and Assistant Surgeon, now at Fort McIntosh, Texas, will report to the commanding officer, Third Cavalry, to accompany Troop I of the regiment to Fort Sill, Oklahoma Territory.

CHAPIN, A. R., Captain and Assistant Surgeon, is granted leave of absence for one month.

APPEL, DANIEL M., Captain and Assistant Surgeon, is relieved from further duty as attending surgeon for the officers and enlisted men on duty at the World's Columbian Exposition, and will report to the commanding general, Department of the Missouri, Chicago, Ill.,

for duty as Attending Surgeon and Examiner of Recruits in that city.

Naval Intelligence.—*Official List of Changes in the Medical Corps of the United States Navy for the week ending June 24, 1893:*

GUTIÉRAS, D. M., Passed Assistant Surgeon. Detached from the Naval Hospital, Philadelphia, and ordered to the Naval Laboratory, Brooklyn, N. Y.

KENNEDY, R. M., Assistant Surgeon. Detached from the Coast-Survey Steamer Bache and ordered to examination for promotion.

BARBER, GEORGE H., Passed Assistant Surgeon. Detached from the U. S. Steamer Miantonomoh and ordered to the Coast Survey.

Marine-Hospital Service.—*Official List of the Changes of Stations and Duties of Medical Officers of the United States Marine-Hospital Service for the five weeks ending June 10, 1893:*

BALLHACHE, P. H., Surgeon. Granted leave of absence for four days. May 22, 1893.

PURVIANCE, GEORGE, Surgeon. Detailed as chairman of the Board of Examiners. May 8, 1893.

HUTTON, W. H. H., Surgeon. Granted leave of absence for ten days. June 1, 1893.

HAMILTON, J. B., Surgeon. Granted leave of absence for four days. June 1, 1893. Granted leave of absence for seven days. June 7, 1893.

GASSAWAY, J. M., Surgeon. Detailed as member of the Board of Examiners. May 8, 1893.

STONER, G. W., Surgeon. To represent the service at the meeting of the American Medical Association. June 2, 1893.

IRWIN, FAIRFAX, Surgeon. To proceed to Marseilles, France, for duty. May 16, 1893.

CARTER, H. R., Surgeon. Detailed as recorder of the Board of Examiners. May 8, 1893. To report in Washington, D. C., for special temporary duty. May 20, 1893. To proceed to Delaware Breakwater Quarantine for temporary duty. May 31, 1893. To proceed to Baltimore, Md., for temporary duty. June 2, 1893.

CARRINGTON, P. M., Passed Assistant Surgeon. To proceed to Bremen, Germany, for duty in the office of the United States Consul. May 16, 1893.

KINTOUN, J. J., Passed Assistant Surgeon. To proceed to Chicago, Ill., for special duty. May 8, 1893.

GOODWIN, H. T., Passed Assistant Surgeon. To proceed to Detroit, Mich., for temporary duty. May 27, 1893.

STONER, J. B., Passed Assistant Surgeon. Granted leave of absence for twenty days. June 5, 1893.

GEDDINGS, H. D., Passed Assistant Surgeon. To proceed to Reedy Island, Del., for special temporary duty. June 7, 1893.

CONDUCT, A. W., Assistant Surgeon. Granted leave of absence for thirty days. June 5, 1893.

NORMAN, SEATON, Assistant Surgeon. Granted leave of absence for six days. May 12, 1893.

less reaction and traumatism—not that the traumatism of peritomy is at all serious or the healing imperfect or the operation itself objectionable, only the cautery, it seems to me, is as effective, rather more simple, and as rapid in its results. Of course the indication is the same for each method, and it may be simply a matter of choice as to which should be used, but the results are, in many instances, remarkable.

In cases of ulcerative keratitis I first make a careful inspection of the cornea and cauterize, at the sclero-corneal margin, any vessel or vessels feeding the ulcer, and rarely see much resulting pain or reaction. Then, with the subsequent aid of the usual remedies suitable for these conditions, I find far more satisfactory and speedy results.

I do not always use the cautery in cases of extensive pannus, nor do I always venture to cauterize all the blood-vessels at once, but I am of the opinion that this method (or peritomy) will be useful in the large majority of cases of ulcerative keratitis. Either the galvano-cautery or the platinum probe heated in the flame of an alcohol lamp may be used.

HENRY W. RING, M. D.

Proceedings of Societies.

THE AMERICAN PEDIATRIC SOCIETY.

Fifth Annual Meeting, held at West Point, N. Y., on May 24, 25, and 26, 1893.

The President, Dr. A. D. BLACKADER, of Montreal, in the Chair.

The President's Address.—After a retrospective view of the scientific labors of the society during the past five years, in which he showed the breadth of pædiatrics, the president spoke more particularly of the importance of a proper knowledge and treatment of the constitutional conditions occurring in children, that vicious tendencies might be checked or corrected and vigorous and healthy adults be reared.

This Year's Failures in Diphtheria.—Dr. M. P. HATFIELD, of Chicago, read a paper thus entitled. He reported six cases of diphtheria, all ending in death from various causes. In the first case he thought the result might possibly have been different had he insisted, on the evening when he first saw the child, on making a thorough examination. As it was, in order to avoid disturbing the child late at night, he had lost precious time which might have been used in combating the disease. In another case he blamed himself for not having paid more attention to the backache, anorexia, and vomiting which indicated the onset of a diphtheritic nephritis, for by using prompt and energetic treatment he had saved the patient's sister. In still another case death had occurred very suddenly from paralysis of the heart while the patient was sitting up in bed on the sixth day of the disease. The writer took a gloomy view of the operation of intubation, as all the patients whom he had intubated, or had others intubate for him, had died. He thought two of the six might have been saved had tracheotomy been performed.

Dr. W. P. NORTHRUP, Dr. W. D. BOOKER, Dr. J. LEWIS SMITH, and Dr. A. CAILLÉ spoke of the advantages of intubation, even in the hands of the general practitioner. Dr. Northrup argued from his pathological studies of cases terminating fatally after intubation, and of others of death from laryngeal diphtheria, that it was rare that tracheotomy offered any advantages over intubation, and that when the membrane once developed below the cricoid cartilage, it always spread down

Letters to the Editor.

REGARDING PERITOMY.

NEW HAVEN, CONN., June 17, 1893.

To the Editor of the New York Medical Journal:

SIR: The favorable results of any treatment for the relief or cure of ulcerative keratitis should be welcomed by the profession, and the article in the *Journal* of the 17th inst. by Dr. John DUBB, of Richmond, Va., on the value of peritomy was of particular interest to me, as my experience and convictions coincide very closely with his; but where he practices peritomy I make use of the cautery with as good results and, perhaps,

into the fine bronchial tubes. Why the cricoid cartilage should be the dividing line he could not say, but such had been his experience.

Dr. J. E. WINTERS thought that very early intubation or tracheotomy would often prevent this extension of the membrane downward.

Dr. A. JACOB, as a result of extensive experience in tracheotomy, took exception to the statement that the cricoid cartilage was to be considered as any such dividing line in the extension of this process. He thought the author of the paper was right in reproaching himself for not having insisted upon the family carrying out the nasal treatment more efficiently, not that it might have altered the result in this particular case, but on general principles, for one had no right to consider the feelings of the relatives when by so doing one jeopardized the patient's life. As a result of the systematic use of nasal irrigation, it could no longer be held that a person who had nasal diphtheria was necessarily doomed. Again, the case of heart failure carried with it an important lesson, and that was that we should not wait until symptoms of collapse set in, but, knowing that diphtheria was apt to terminate in fatal syncope, we should, from the very beginning, use alcohol and cardiac stimulants freely.

Dr. J. LEWIS SMITH spoke of the much better results which Dr. O'Dwyer and others were getting with intubation since they had begun to employ calomel sublimations in conjunction with it. From ten to thirty grains of calomel were heated on a tin plate over a lamp, and the child, placed under a tent or sheet, was made to inhale the fumes from the burning calomel for not more than fifteen minutes at a time. These sublimations should be repeated every two or three hours. Any one who was skeptical about the penetrating power of this remedy when so administered need only place himself under the tent to be convinced of his error, for even a slight exposure to the fumes often left an irritative cough that lasted for hours, and longer exposure had been known more than once to give rise to salivation. A resort to this treatment, even in cases of laryngeal diphtheria in which it seemed almost impossible that anything but an operation was likely to be of benefit, would in a certain proportion of cases save life and render an operation unnecessary.

Dr. T. M. ROTCH, of Boston, said that anatomical as well as clinical proof of the efficiency of nasal irrigations in diphtheria was not wanting. Some years ago, at his suggestion, Professor Dwight, of Boston, had undertaken an anatomical study of the nose and throat which had resulted in demonstrating that the tonsils were more excretory than secretory in their function, while the function of the naso-pharynx was chiefly secretory.

The Value of Peroxide of Hydrogen in Diphtheria was the title of a paper by Dr. J. LEWIS SMITH, of New York. Finding, as others had done, that the ordinary preparations of the peroxide of hydrogen when diluted with two volumes of water sometimes increased the irritation of the affected parts, and even produced a fibrinous exudation as a result of the irritation produced by their acid impurities, he had found that Marchand's solution required five grains of sodium bicarbonate, the Oakland Company's peroxide three grains, and Squibb's preparation two grains and a half to neutralize the free acid. As Dr. Squibb had informed him that a neutral or alkaline solution of peroxide of hydrogen would decompose at ordinary temperatures at the rate of two or three volumes a day, the sodium bicarbonate must be prescribed separately from the peroxide, and only added each time before using. He also called attention to the fact that Dr. Squibb prepared for the use of the medical profession a small set of reagents with which the physician could make for himself a fresh solution of peroxide of hydrogen.

A Case of Laryngeal Diphtheria was reported by Dr. W. D. BOOKER, of Baltimore. A little girl who had been suffering during the past winter a good deal with bronchitis was suddenly attacked, on April 6th, with an alarming laryngeal stenosis associated with great prostration. Intubation was performed, but she grew worse steadily, was seized with bronchopneumonia, and died on April 10th. During this time no membrane could be observed in the throat. At the autopsy, which was made immediately after death, the tonsils, pharynx, uvula, and soft palate were absolutely free from exudation, yet, beginning at the upper margin of the posterior surface of the epiglottis and involving the mucous membrane of the larynx, trachea, and primary bronchi, there was a grayish-white false membrane, in some places a millimetre in thickness and not easily separated from the underlying mucous membrane. In its clinical features this case would be considered a typical one of true croup, but a careful bacteriological examination showed it to be diphtheritic. The writer stated that for the purpose of making cultures he had gouged out large portions of various organs, for the diphtheritic bacilli gathered in such small numbers in the organs that he had been unable to find any of them in sections from these organs. It was very remarkable that in this case the bacilli passed over the pharynx; he could only explain it on the supposition that the previous bronchitis had rendered the parts below the pharynx alone vulnerable. It was evident from the bacteriological examinations that the diphtheritic bacilli were not confined to the local lesion, but it was still questionable whether these bacilli gathered in the organs in large enough numbers to be of practical importance.

The last two papers were discussed together.

Dr. AUGUST SEIBERT, of New York, detailed some experiments which he had made on the comparative solvent action of peroxide of hydrogen, aqua chlori, and Labarraque's solution on diphtheritic membrane. He had taken fresh pieces of membrane of the same size and immersed them for ten minutes in the same quantity of each test solution. Bacilli and streptococci were obtained from the piece that had been in the peroxide of hydrogen, the cultures were negative with the aqua chlori, while the membrane placed in Labarraque's solution had been completely dissolved at the end of ten minutes. Dr. Booker's case showed that the bacilli entered the system below the membrane, and emphasized the importance of the treatment which he personally advocated—viz., that this was the locality at which they should be attacked with remedies.

Dr. J. H. FRITZTIGHT said he had overcome the irritating properties of peroxide of hydrogen by adding to it lime water, which not only counteracted the acidity, but exerted a solvent action on the membrane. It should be prescribed in a separate bottle from that containing the peroxide. An ounce should be added to three ounces of Squibb's preparation.

Dr. A. CAILLÉ, of New York, drew one practical lesson from Dr. Booker's case, and that was that anemic or rachitic children who had been suffering from bronchitis should be removed from a locality in which it was known that diphtheria was prevailing, for we could not prevent diphtheritic infection of the respiratory passages as we could that of the nasal cavities.

Dr. HENRY KOPLIK, of New York, said that a mixture of bouillon and blood-serum furnished the most sensitive culture medium for diphtheritic bacilli.

Brief Notes on Antipyretic Drugs in the Febrile Affections of Children.—Dr. J. P. CROZER GRIFFITH, of Philadelphia, read a paper thus entitled. Cases were cited showing the beneficial action of antipyretic drugs when administered not because of the degree of temperature but because of the existence of nervous symptoms dependent upon the fever.

Dr. CHRISTOPHER, of Chicago, shared the position taken by the author, and added a caution against using such remedies continuously.

Questions of Nomenclature.—Dr. ROTCH presented the report of the committee on the revision of the nomenclature of gastro-intestinal diseases. It was especially urged that the term "dysentery" should be discarded. The report favored a classification according to a pathological basis.

Dr. F. FORCHHEIMER, of Cincinnati, presented the report of the committee on the revision of the nomenclature of diseases of the mouth.

After a long discussion on these reports, it was thought best, in view of the importance and complexity of the subjects, that no action be taken on the reports until the next annual meeting.

Proctitis in Early Infancy.—Dr. LOUIS STARR, of Philadelphia, read a paper on this subject. These cases were characterized by small, frequent movements of the bowels with straining, greenish or yellow movements with some mucus, and moderate emaciation. On everting the mucous membrane of the rectum, it would be found to be intensely red and sometimes superficially ulcerated. There might also be a catarrhal inflammation of the mucous membrane of the mouth, with a peculiar T-shaped ulceration at the junction of the hard and soft palate, the vertical stem of the T extending down to the uvula. The etiology was obscure; in very young infants the disease might be due to the meconium. The treatment consisted in the use of cleansing injections of salt and water, two to eight ounces being used each time and given with a fountain syringe which was only slightly raised above the level of the baby's body. These should be followed by enemata of olive oil. In obstinate cases it was well to use injections of nitrate of silver—one to two grains to two ounces of water—following these with an enema of salt and water. After using from one to three such injections, at intervals of three or four days, the simpler treatment already outlined would usually suffice to complete the cure. Olive oil should be used instead of water for cleansing the buttocks when there was excoriation. Most of the cases he had seen had occurred among well-to-do people and with children fed at the breast, and the treatment for the diarrhea of indigestion had been of no avail.

Dr. FRUHNIGHT recalled a child seen by him during the past year with similar but severer symptoms. The use of copious enemata of boric-acid solution and, internally, of iodide of iron had brought about a cure in about two weeks.

Dr. JACOBI said that proctitis was ascending or descending, or arose *in loco*. He thought the nitrate-of-silver injections, even when carefully given by the physician, were apt to increase the tenesmus, and he preferred starch water or bismuth and water.

Acute Scleroderma.—Dr. WILLIAM OSLER, of Baltimore, read a paper in which he reviewed the literature, and reported a case occurring in a child of fourteen months, who also had an acute croupous pneumonia. The induration first appeared on the eighth day of the pneumonia, and the hardness spread within twenty-four hours over the entire body, making it feel like a block of wood. At this time the temperature in the rectum was 99° F. Death occurred on the next day. The body was as hard and stiff as if frozen, and the only parts not affected were the genitals and scalp. Microscopic examination showed the structure of the skin to be more like that of those portions of the body which were naturally but slightly movable.

Dr. NORTHRUP referred to a case of sclerema neonatorum which he had presented to the society at its first meeting. In his case the temperature had been decidedly subnormal, and the child had been known in the institution to which it belonged as "the stone baby." After examining critically with

the microscope many sections from this case and comparing them with sections taken from healthy children of the same age, he had found that there was no characteristic morphological appearance.

Dr. JACOBI said the fact that in the case reported in the paper the patient did not have a subnormal temperature, as was usual in these cases, could be readily explained by the simultaneous occurrence of pneumonia. The scleroderma of adults and young children he had always looked upon as a neurosis. The clinical phenomena of scleroderma were well explained by the theory that there was an effusion of blood containing more than the normal quantity of coagulable material.

Dr. KOPLIK said that in the cases which he had seen among the new-born at Prague the induration had developed first on the inner side of the thighs, then on the buttocks and cheeks.

Whooping-cough was the subject of a special discussion.

Dr. GRIFFITH, of Philadelphia, referred briefly to many of the recognized methods of local treatment. Cocaine in the form of a spray was sometimes useful, but, as Dr. Holt had pointed out, it sometimes produced dangerous symptoms. From a review of the literature of the subject, the speaker had concluded that pertussis was due to an infectious germ circulating in the blood, and not to a local process.

Dr. FORCHHEIMER dealt with the constitutional treatment, and spoke of the desirability of employing prophylaxis, but of the almost insuperable difficulties in the way of carrying out this treatment. For example, in the first stage it was impossible to make the diagnosis, yet he thought that at this time the disease was just as contagious as in the spasmodic stage. Then, again, in the third stage it was well-nigh impossible to keep children isolated. The poor considered the schools a place of safe-keeping for their children, and felt that it was quite a hardship if they were prevented from attending; besides, even if the children were kept away from school, after school hours they would be found to come together and play on the street. Belladonna or atropine and quinine were most generally accepted as efficient remedies in pertussis, but there was much conflicting testimony in regard to their efficacy. Idiosyncrasy seemed to exert a powerful influence, for different members of the same family would be found to behave very differently with the same remedy. The difficulty in arriving at definite conclusions regarding the action of such remedies was that no one observer had a sufficient number of patients under proper control to make his observations and deductions thoroughly reliable.

Dr. OSLER said he had not found that any remedy, except perhaps quinine, exerted any marked influence on pertussis, and he should not expect a different result, for he regarded it as a specific disease running a definite course. He hoped that some one who had a large number of cases of pertussis at his command would have moral courage enough to observe a series of, say, fifty cases without administering any medicine except a placebo; in this way we might at last ascertain the true natural history of the disease.

Dr. HENRY DWIGHT CHAPIN, of New York, spoke of the complications of pertussis, which he believed accounted chiefly for the great mortality attendant upon this disease, and those complications, he was convinced, were in large measure avoidable by instructing the parents more carefully regarding the danger of exposing the patients to all kinds of weather. While pneumonia was a very common and fatal complication, many children could be saved by sufficiently early and energetic treatment. Pulmonary collapse also was a very frequent complication. Where the cough persisted long after the usual time, it would usually be found that the tracheal and bronchial glands had become enlarged. The eruptive fevers often complicated pertussis, and this was particularly true of measles, in which

case both diseases were more than usually severe. The speaker laid special stress upon the great susceptibility of convalescents from pertussis to tubercular infection.

Heart Strain in Pertussis; its Effects and Treatment.—

Dr. HENRY KOPLIK, of New York, read a paper thus entitled. He described the mechanical effect of the paroxysms on the pulmonary and systemic circulations. During the paroxysm auscultation showed that the heart's action was very irregular, and that at times the sounds became almost inaudible, while in the intervals of the paroxysms the pulse was more irregular than was normal with children. He presented sphygmographic tracings which showed, after making due allowance for the dicrotism, which was always more marked in children than in adults, that the dicrotism in pertussis children was much more prominent than in healthy children. In thirty-six cases which the author had examined for albuminuria its presence had been proved in eighteen, although the quantity of albumin had never been great. In the treatment of this condition he had found digitalis of great service. Its administration should be begun as soon as there was oedema about the face, as this was the first sign of heart strain, and a minim of the tincture should be given for each year of life up to three years, and for older children proportionate doses.

Dr. L. EMMETT HOLT, of New York, opened the general discussion on the treatment of pertussis. He did not think any remedy shortened the course of the disease, but certain drugs exerted a very decided controlling influence on the severity and frequency of the paroxysms. In considering the action of a given remedy in pertussis, it was very important to take into account the stage of the disease at which its use was begun. He had made very careful observations in the New York Infant Asylum on the action of antipyrine, the children being watched for a week, and their condition noted before the treatment was begun; then the antipyrine was given for a week, after which its use was discontinued. Careful notes were kept throughout these three weeks in each case, and it was found that in four out of five cases the antipyrine diminished the number of paroxysms, and that in a smaller number the severity also was lessened. Its effect was temporary, but, on the whole, he had found it more efficient than phenacetine, acetanilide, and similar drugs. He began by giving six grains a day to an infant of six months, gradually increasing the daily dose to eight grains. He had been particularly surprised at the enormous mortality associated with pertussis pneumonia in institution children, fifty children having died out of a series of sixty cases.

Dr. NORTHRUP spoke of "lung-strain" in pertussis, as exhibited by an unusual degree of emphysema of the lungs. For this reason alone, if for no other, he thought it was very desirable to use any drug known to have the power of mitigating the severity of the paroxysms.

Dr. FREIGHT related his experience during the last year and a half with bromoform in pertussis. He gave it in doses of one or two drops along with a little spirit as a solvent. In most cases it reduced both the frequency and severity of the attacks. The fresh-air treatment was very important, and for the poor of the city it was a good plan to send them out on the ferry-boats as much as possible.

Dr. J. E. WINTERS, of New York, asserted that pertussis was a more fatal disease of childhood than either diphtheria or scarlatina, and it was so chiefly through its complications and sequelæ. These were dependent upon the frequency and severity of the paroxysms, which in turn were amenable to proper management—change of air, attention to the alimentary canal, counterirritation, etc. Of drugs, codeine had served him best, given to a child of two years in doses of a twelfth of a grain every eight hours. He believed that all opiates

might be given with perfect safety to the youngest and most delicate infants, if the precaution was taken to allow a sufficient interval to elapse between the doses. Many deaths which were attributed to eclampsia, pneumonia, and tuberculosis were in reality due to the sequelæ of pertussis.

Dr. SEIBERT said that the use of carbolic acid, both in the form of a spray and internally, had proved useful in infants suffering from pertussis, but not in older children. The fresh-air treatment as advocated by him consisted in keeping the windows open all day, even in rainy weather, and at least one window at night. There was but little difficulty in getting the mothers to obey these instructions, as they soon learned that their children were most comfortable when they were the most out of doors. The ideal treatment he considered the use of this method of securing plenty of fresh air combined with the administration of large doses of quinine every night, or night and morning.

Dr. A. CAILLÉ said that in the management of pertussis he insisted on plenty of fresh air, both day and night, with a dose of antipyrine at night in the severer cases and the systematic irrigation of the nasal cavities with boric-acid solution to prevent possible infection with diphtheria.

Dr. J. LEWIS SMITH said he had been guided in the treatment of this disease by the belief that it was due to a bacillus whose habitat was the upper respiratory passages, and accordingly he had generally employed antiseptic inhalations. Recently he had tried Moncorvo's method of applying a solution of resorcin with a brush or spray, but it had not proved uniformly successful. For older children these antiseptic inhalations were conveniently carried on by letting them use Robinson's inhaler containing creasote and terebene. He did not see how any one could doubt the efficacy of fresh air in allaying the severity of the attacks. If a child did not appear so well and bright as usual during the intervals of the paroxysms it was safe to infer that some complication was impending.

The Treatment of Constipation in Early Infancy.—Dr.

HOLT opened a discussion on this subject. He said that there must be a certain bulk to the stools in order that there might be regular and easy evacuations from the bowels, and an examination of normal stools of infants showed that they contained from twenty to forty per cent. of fat. From this we might infer that an infant's food must contain much more fat than could be absorbed. It was not surprising that we saw habitual constipation frequently among children who were fed on milk which was deficient in fat. It could not be denied that some constipated children were healthy, and in such cases it was fair to assume that there was enough fat in their food to supply the requisite nutriment, but not enough to give regular stools. Good breast milk contained four per cent. of fat, and cow's milk a little less; hence, as most of the fat was absorbed, the stools consisted chiefly of hard casein. Under such circumstances the substitution of good rich cream for some of the milk often relieved the constipation. The bowels of a nursing infant were not so easily regulated, but the same indication might be more or less successfully met by giving before nursing one or two teaspoonfuls of cream to the child. The quantity of casein in the mother's milk might be reduced by insisting that she should exercise freely in the open air. He had not found that the addition of milk sugar tended to relieve the constipation, and it was well known that most dispensary children were constipated, although they were quite commonly fed on condensed milk. Oatmeal seemed to owe what little effect it had in relieving constipation to the mechanical irritation produced by particles of the grain, for when it had been cooked for a long time and carefully strained, its relaxing action on the bowels was no longer appreciable.

Dr. LEROY M. YALE, of New York, took up the local treatment. He was of the opinion that massage, if faithfully carried out, even though unscientifically performed, was a valuable means of treating constipation in infants. The mother or nurse was instructed to do this by making small circular movements with the tips of the oiled fingers over the course of the colon, beginning in the right iliac fossa and passing upward along the ascending colon, then transversely, and finally down on the left side. It was best done on an empty stomach. Rectal constipation was the commonest variety of this very common ailment of childhood, and, in his opinion, it was largely due to the fact that when the child evacuated the bowels in the conventional way, sitting on a high seat over a rather wide opening, defecation was effected at a great mechanical disadvantage. The most favorable posture was that of squatting. He had rarely observed undue irritation from the use of suppositories, but on several occasions he had seen a belladonna rash develop after the use of a well-known and popular proprietary suppository which was sold under an innocent name. The dilatation of the bowel so commonly present in constipated infants was quite as likely to be the result of the retention of feces as to be due to the habitual use of enemata.

Dr. C. P. PUTNAM, of Boston, was expected to read a paper on the medicinal treatment of constipation in infants, but in his absence his paper was read by the secretary. He said that castor oil, when given in small doses, was very apt to interfere with digestion, and, if administered in larger doses, its after-effect was to increase the constipation. Senna, in the form of the compound licorice powder, did not lose its effect easily. Phosphate of sodium was the best saline cathartic for children, and olive oil and cod-liver oil were both useful in many cases.

Dr. LOUIS STARR opened the general discussion of this subject. He said he had used with great satisfaction, in addition to other recognized methods of treatment, a suppository composed of a twenty-fourth of a grain of extract of belladonna, a grain of purified aloes, and ten grains of cacao butter. They were used at first twice a day, the frequency being gradually reduced.

Dr. FRUITNIGHT emphasized the value of giving the child plenty of water in order to render the stools more fluid.

The Preservation of Milk.—Dr. H. D. CHAPIN, of New York, read a paper on this subject. It dealt with some experiments which he had made regarding the effect of static electricity in preventing the decomposition of milk, and also regarding the preservative action of certain chemical agents when added to the milk. He stated that one experimenter had been able, by subjecting milk to the action of static electricity for twenty minutes, to keep it sweet for nine days, and for a much longer time if the milk was occasionally subjected to a repetition of the electrical application. Under his direction experiments had been made on milk with both static electricity and a galvanic current of about thirty milliamperes. While they were not conclusive, he was led to believe that the subject was worthy of further study and research. Carbonated milk, kept in ordinary siphons, had been found to keep well, but this method of preserving milk had not proved a commercial success. The author said he had been led to try the effect of adding peroxide of hydrogen to milk, as, when so added, the peroxide of hydrogen decomposed, giving off one atom of oxygen and leaving water. His experiments, he thought, showed that a small percentage of peroxide of hydrogen would check the lactic-acid fermentation in milk. Incidentally, Dr. Chapin exhibited some of the residue taken from five hundred quarts of milk by means of a separator. The milk was from what was supposed to be a very well regulated dairy. He also exhibited

a sample of a new evaporated cream which was about to be put on the market.

Dr. SEIBERT said he had been especially interested in the experiments with the peroxide of hydrogen, for they showed that a two-per-cent. solution of the peroxide in milk was not able to kill the germs.

Dr. ROTCH thought such efforts as these were in the wrong direction; it should be rather the aim of the physician to look after the proper conduct of the dairy and the measures necessary for securing a clean and fresh milk. Evaporated milk did not remain sterile for any length of time after the can was opened.

Dr. KOPLIK recalled the fact that Lister had succeeded in keeping milk indefinitely by properly cleansing the udder of the cow. As the centrifugal machine separated the bacteria along with the cream, skimmed milk was comparatively free from these micro-organisms.

Dr. CAILLÉ said that, as peroxide of hydrogen was immediately decomposed by milk into oxygen and water, it was not only a harmless but a useless addition to the milk. He suggested that if evaporated cream was put up in ounce cans it might prove very convenient.

A New Antiseptic, Bismuth Naphthol-hydrate, was presented by Dr. CHAPIN. The chemist who prepared it, Mr. Lascar, apothecary to the Demilt Dispensary, New York, had said it contained about fifty per cent. of oxide of bismuth, was a much finer powder than ordinary bismuth, was fairly soluble in hot water, and was more potent than beta-naphthol in arresting fermentation. Ten grains of this new substance added to eight ounces of putrefying urine were sufficient to arrest the process, and the same quantity added to sixteen ounces of starch paste which was undergoing acid fermentation at once arrested the fermentation. Dr. Chapin said he had given it to a few children in doses of from two to five grains, in powders or suspended in mucilage. He thought it would prove to be a very valuable and non-toxic intestinal antiseptic.

A Gastric Neurosis in Childhood.—Dr. IRVING M. SNOW, of Buffalo, read a paper thus entitled. The subject of this affection was the eight-year-old daughter of a physician, whose antecedents were distinctly neurotic. There was a history of her having suffered for a number of years from curious attacks of vomiting, which recurred at intervals of about six weeks, and lasted from five to sixteen days. At intervals of three or four hours, during these attacks, there would be a burning sensation in the stomach, followed by nausea and the vomiting of a very acid fluid. There was evidently a periodical secretion of hyper-acid gastric juice. Her digestion at other times was good, and these attacks would be brought on by slight worry or excitement. They would terminate very abruptly. Large doses of potassium bromide and chloral given by the rectum had proved the most successful in the treatment, combined with proper attention to physical culture and to the general health.

Dr. HOLZ reported a very similar case which he had observed in conjunction with Dr. C. Herter. It had at last been noted that during the intervals the proportion of uric acid to the urea was 1 to 40, but that during the paroxysms it sank to 1 to 150. By excluding sugar from the child's diet and limiting the quantity of starches he had been greatly benefited. Two physicians had previously seen the child in these attacks, and had made a positive diagnosis of tubercular meningitis. This child was the son of a physician, and also came of a highly neurotic family.

Dr. CHRISTOPHER reported a similar case occurring in an adult, in which the symptoms had been associated with the elimination of uric acid, but the dietetic treatment which he had employed in this case with success had been directly the opposite of that used by Dr. Holt.

Dr. ROTCH said he had seen many such cases, and had written and published an article on this subject eight years ago. The causes were many and various, the attacks were usually self-limited, and the patients always recovered ultimately. In his opinion, dietetics had no place in their treatment.

Dr. SEIBERT had also had under his care a case of this kind in which three different consultants had made a diagnosis of meningitis. In each case the exciting cause had been the accumulation of feces in the ascending colon, and treatment directed to the relief of this difficulty had proved highly successful.

Dr. FORCHHEIMER had seen many of these cases, and entertained the theory that, owing to impairment of the filtering function of the liver, certain toxalbumines were present in the blood, and the attempt of the stomach to eliminate them gave rise to these attacks. This view seemed to be confirmed by the dietetic treatment, which had given him the best results.

Dr. CAILLÉ had found bile in the vomited matter and in the urine for a short time after the paroxysms.

Dr. SNOW expressed his surprise that the cases were so common in the experience of the members, as he had been unable to find mention of them in medical literature.

The Etiology of Incontinence of Urine was the subject of a paper by Dr. B. K. RACHFORD, of Newport, Ky., in which he stated that at the very beginning of life there was a normal incontinence. Age was an important factor, as it had been shown that functional immaturity of the nervous centers caused inhibition of reflex acts. The principal etiological factors were the instability of the nerve centers, the existence of anemia, and reflex irritation. Anemia, which was a most potent cause, was produced by tuberculosis, bad feeding, rheumatism, and syphilis in children, and the frequency with which these were operative was in the order named. The writer quoted experiments in which by partial closure of blood-vessels in animals a local anemia of greater or lesser degree had been produced. In these experiments it had been found that the longer this artificial anemia was kept up the more irritable did the nerve centers supplied by these vessels become.

Those who took part in the discussion of this paper dealt chiefly with the relation of anemia to this condition of incontinence.

The Treatment of Certain Forms of Anæmia in Children.

—Dr. F. FORCHHEIMER, of Cincinnati, read a paper on this subject. He said the question had often been asked why one should prescribe such large quantities of iron when the total quantity present in a person weighing seventy kilogrammes was only a little over three grammes. The answer that it must be first converted into an albuminoid before it can be absorbed was not satisfactory, for it was found that absorption was not favored by using an albuminoid of iron. Clinical observation showed that, as a result of increasing the quantity of hæmoglobin, not only was more carried by the corpuscles, but the number of red blood-corpuscles was increased also. From a study of seventy-one cases, the writer concluded that in the anemia of children the hæmoglobin was reduced more than the number of red corpuscles. Believing, as he did, that hæmoglobin had its principal source in the intestine, he had treated anemia with intestinal antiseptics, such as salol and hydronaphthol, and with arsenic, which acted on the formation of hæmoglobin. Salol or hydronaphthol, combined with iron, acted very well, but he had obtained almost marvelous results from the administration of salol before meals and of blood in some form after meals.

Dr. CAILLÉ cautioned against taking the position that iron was the only remedy appropriate for anemia. In large doses given to children it frequently aggravated the condition by im-

pairing digestion, while hydrochloric acid, by improving digestion, often succeeded much better.

Dr. KOPLIK reported a case of extreme anemia in a child in which complete recovery had taken place as a result of careful attention to diet without any systematic medication.

The Treatment of Rhachitis with the Lacto-phosphate of Calcium.—In a paper on this subject, Dr. J. HENRY FRUIT-NIGHT said that lime in the form of the phosphate was a regenerator of nerve and bone tissue, and its effects were permanent. Lactic acid increased its solubility, and hence rendered it a more convenient and efficient remedy. In the form of the official syrup of the lacto-phosphate it was readily given to children, and in the cases reported it had certainly seemed to be of great benefit.

A Case of Erysipelas of the Scalp and Face in an Infant aged Six Weeks was reported by Dr. SAMUEL S. ADAMS, of Washington. The case was of unusual interest not only because so young an infant had recovered, as erysipelas in infants under six months was almost invariably fatal, but because the blush of erysipelas had not made its appearance until five days after the first constitutional symptoms.

Dr. SEIBERT could not understand how the eruption could be delayed for such a long period, as in experimental erysipelas this stage was only twenty-four hours.

A New Incubator.—Dr. T. M. ROTCH, of Boston, described a new incubator which he had had constructed for the benefit of premature infants. Such an apparatus, he maintained, should be made of metal in such a manner that all parts could readily be cleaned and sterilized; it should be portable so that it might be carried from a central station to any house where it might be needed; the ventilation should not be left to the nurse, but should be automatic and thorough; its construction must be such as to admit of easy and perfect adjustment to any temperature which the physician might desire; the air admitted to the incubator must be freed from dust and organisms, and in some cases must be mixed with an additional portion of oxygen; and provision should be made for determining from time to time the weight of the infant. The incubators hitherto employed had been very crude, and had been particularly troublesome to manage on account of the difficulty of properly ventilating them. The slightest neglect on the part of the attendant often cost the life of the little one by suffocation. In the new incubator perfect ventilation was secured by an apparatus actuated by clock-work or by a candle in the flue, and the attendant had only to glance at a little anemometer to see whether or not it was working properly. The baby was heated equally by radiation on all sides, and the air it breathed was freed from impurities by filtration through cotton. The child lay on a bed which was a part of an ingeniously constructed balance, and to ascertain the weight of the infant at any time it was only necessary to touch a button and look through a glass window. In feeding the child, the nurse's arms were surrounded by a sleeve or jacket of rubber, so as to keep out as far as possible the external air. The incubator was constructed of polished metal, and weighed a hundred and fifty pounds. It presented a handsome appearance, and at present formed a part of the Harvard exhibit at the World's Fair.

Clinical reports were presented by Dr. HOLT, on Meningitis complicating Pneumonia; by Dr. WALTER LESTER CARR, on Sarcoma of the Back in a Baby; and by Dr. F. HUBER, on Abscess of the Lung in an Infant of Thirteen Months and a Half; Operation: Recovery.

The following papers were read by title: Intestinal Fever, by Dr. JACOB; A Clinical Study of Rheumatism in Children, by Dr. FLOYD M. CRANDALL; and Some Points in Connection with the Etiology of Rhachitis, by Dr. J. LEWIS SMITH.

Dr. JOHN M. KEATING, of Colorado Springs, was elected president for the ensuing year.

Miscellany.

The New York City Health Department and the Diagnosis of Diphtheria.—The department has recently issued the following circular of information concerning the use of bacterial cultures by the health department for the diagnosis of diphtheria:

Recent investigations have shown that a considerable proportion of pseudo-membranous and exudative inflammations of the throat and upper air passages, commonly considered as diphtheria and having the anatomical appearances found in diphtheria, are not true diphtheria. These cases may be called false diphtheria.

It has also been shown that a considerable number of cases considered to be false diphtheria are really true diphtheria. While in true diphtheria the mortality is very high and the danger of transmission to others is great, in false diphtheria the mortality is low and the danger of infection slight. The diagnosis between true and false diphtheria can be made by bacteriological examinations within twelve hours, while without their assistance it is difficult or impossible.

The health department is now prepared to make use of bacterial cultures for diagnosis in all cases of suspected diphtheria occurring in the city, and desires that in every case either the physicians should themselves make the inoculations or should authorize an inspector to make them. They should be made in every suspicious case at the earliest possible moment. It is only in this way that the full benefit of a positive diagnosis is obtained, for during convalescence the specific organisms often disappear from the throat. The inoculations are made by gently rubbing a cotton swab against the throat, and then drawing it over the surface of the culture medium. When the physician desires to make the culture himself (and this is usually the better plan, for it can be done earlier and is more agreeable to the family), he can obtain, free of cost, a culture tube and swab and the simple directions necessary for their use at any one of the apothecaries' whose addresses are given below. After the inoculation the tubes are to be returned at once to the apothecary from whom they were obtained. The tubes will be collected by the department every evening. If, on the other hand, the physician desires an inspector to make the inoculation, he is requested to state this when the notification of the case is sent to the department.

The diagnosis will be ready in every case by noon of the following day. The attending physician can obtain this immediately by telephoning to the laboratory (telephone number, 1191 Spring), or, when this is not done, he will be notified by mail.

Cases which prove to be false diphtheria will not be visited by the department. Cases, on the other hand, which prove to be true diphtheria will be subjected to the usual rules and regulations covering contagious diseases.

The culture tubes and swabs can be obtained of the following apothecaries: Fraser, 138th Street and Third Avenue; Spear, 125th Street and Eighth Avenue; Dorn, Ninety-third Street and Ninth Avenue; Dougherty, 411 West Fifty-ninth Street; Rupp, Thirty-sixth Street and Ninth Avenue; Proben, Twelfth Street and Second Avenue; Ottiwell, Ludlow and Broome Streets; Marsh, 125th Street and Madison Avenue; Barnes, 110th Street and Madison Avenue; Hoyppendorf, Sixty-seventh Street and Third Avenue; Schoonmaker, Forty-second Street and Park Avenue; Fraser & Co., Twenty-ninth Street and Fifth Avenue; Bigelow, Eighth Street and Sixth Avenue; Laboratory, 42 Bleeker Street.

The Permanent Organization of the Pan-American Medical Congress.—The American Medical Association's committee has reported, through its chairman, Dr. Charles A. L. Reed, as follows:

Your committee appointed at Washington to effect a permanent organization of an intercontinental American medical congress begs leave to submit its final report as follows:

An organization has been effected under the style and title of the Pan-American Medical Congress, to be held at the city of Washington, D. C., September 5, 6, 7, and 8, 1893, under the presidency of Professor William Pepper, M. D., LL. D., of Philadelphia. The details of the organization are set forth in the published preliminary announcement of the congress, copies of which are respectfully submitted herewith, in both English and Spanish, as a part of this report.

Since the publication of this preliminary announcement an organization has been effected in Paraguay. Your committee is therefore pleased to state that an organization of the Pan-American Medical Congress exists in every State and Territory of the United States, and in every remaining country and colony of the Americas, including the West Indies and Hawaii.

A provision has been adopted since the foregoing publication whereby every medical society—national, colonial, and local—has been made a constituent organization of the congress.

The committee begs leave to report further that the organization which has been effected has been, by the authority you have conferred upon it, and is still very actively engaged in carrying out the practical ends of the congress.

The Senate and House of Representatives at the first session of the last Congress adopted a joint resolution authorizing the President to extend an invitation to the Governments of the Western Hemisphere to send official delegates to the meeting, and to appoint similar delegates on behalf of our own Government. This official invitation has been issued through the Department of State, and all replies so far received have been in the nature of acceptances. The President has indicated that the Government of the United States will be represented at the Congress by six delegates. At the last meeting of the Executive Committee of the Congress a resolution was adopted directing that, in view of the Columbian exercises in progress in America this year, and in view of the relations which have become intimate between the United States and Spain, the Government of the latter country be requested to send delegates to the Congress. It was thought that the exceptional relations of amity existing between the two countries would warrant a course which has been avoided with regard to all other European countries out of deference to the interests of the International Congress which is to meet in Rome.

The National Congress at its last session appropriated fifteen thousand dollars (\$15,000) for the purposes of entertainment of the meeting.

The President of the United States has consented to open the congress in person, and to extend the courtesy of a reception at the White House to delegates and their families.

A special feature of the congress will be the proceedings of the sections in hygiene, climatology, and demography and in marine hygiene and quarantine. The proceedings of these sections will be largely of the nature of a sanitary conference, with particular reference to practical questions of public health and of imminent importance.

With this object in view, every municipality of the three Americas, including the West Indies and Hawaii, has been invited to send an official delegate, and a very large number of acceptances have already been received.

The titles of several hundred papers, accompanied in many instances with abstracts, have already been received from representative medical writers in the English, Latin, French, and Portuguese countries. This, of itself, assures the scientific success of the congress.

Invitations have been extended to representative European scientists to be the guests of the congress, and a number of acceptances have been received.

In conclusion, your committee begs leave to express its appreciation of the spontaneous response to its appeal for funds in the form of advance registration fees from the public-spirited representatives of our profession in America. Let it be remembered, no registration fees will be accepted from members of the congress residing outside the United States. Although money has been realized from advance registrations in amount sufficient to pay some of the preliminary expense of organization, a still larger sum is needed with which to meet accumulated obligations.

It should be held in mind that the congressional appropriation, mea-

ger as it is, will be available only for purposes of entertainment at the time of the meeting, and that the expense involved in publication, correspondence, and clerical work is necessarily very heavy, and must be met at once. The members of the profession are therefore again urgently requested to register at once by paying the fee (\$10) to the treasurer, Dr. A. M. Owen, Evansville, Ind. Those who thus become members of the congress but who may be prevented from attending the meeting will receive a set of the transactions, which, of themselves, promise to be worth more than the amount of the registration fee.

In submitting this, its final report, your committee begs leave to thank the association and its executive officers for cordial support, and the medical press for its energetic and efficient aid in promoting this earnest movement for the unification of the medical profession of all the Americas.

Professor Liebreich on Mineral Waters.—In the *British Medical Journal* for April 22d the *Journal's* Berlin correspondent says:

"The following is an abstract of a paper on Artificial and Natural Mineral Waters, read by Professor O. Liebreich at the Balneological Congress recently held in Berlin. He began by asking: Is chemistry sufficiently advanced yet to produce artificial mineral water equal in all respects to the natural water? The answer can not be in the affirmative. Some substances, such as alizarine, indigo, urea, etc., can be produced synthetically, the artificial product being in every respect identical with the natural one. But in the case of mixtures such as mineral waters are, synthesis is a much more difficult matter. The analysis of each of the first-mentioned substances gives exactly a hundred per cent., while in the case of artificial mineral waters the analyses—even of the most renowned analysts—fall short of a hundred per cent., thus leaving a remainder the nature of which is absolutely unknown.

"Many mineral waters on evaporation leave an organic residuum which goes by the name of glairine. It can not be affirmed with certainty that this residuum is therapeutically efficacious, but just as little can it be denied, and certainly the residuum is not contained in the analyses of the artificial mineral waters. Further, in mineral waters, carbonic-acid gas occurs both free and in chemical combination. In 1882 it was discovered that carbonic-acid gas forms a hydrate—that is to say, that there exist several kinds of carbonic-acid gas. The presence of a carbonic-acid gas hydrate had long been concluded from the existence of another combination that is a derivative of it, namely, carbonic-acid ethyl, a carbonic-acid hydrate, the two hydrogen atoms of which are replaced by two C_2H_5 groups—that is, carbonic-acid ethyl ether. Carbonic-acid ethyl is known for its agreeable taste. It is probably contained in champagne and in other alcoholic effervescent drinks. Ballo was the first to show the presence of carbonic-acid hydrate experimentally. If a magnesium wire be introduced into carbonic-acid gas, no reaction takes place. If a magnesium wire be introduced into water which has previously been saturated with carbonic-acid gas, after some time gas is developed. This gas is not carbonic acid but pure hydrogen. We must conclude that in the water the carbonic-acid gas has been transformed into carbonic-acid hydrate, and this develops hydrogen, as every acid does when brought in contact with metal. It may be supposed that the action of anhydric carbonic-acid gas is different from that of carbonic-acid hydrate. The formation of hydrate takes place quickly in pure water, but very slowly in concentrated salt solutions.

"Now, there are substances which are difficult to demonstrate as such by analysis because they decompose very easily, so that only the products of their decomposition can be shown. Such a substance is carbon-oxide-sulphide (COS), which when alone shows neither the reactions of carbonic-acid gas nor of sulphureted hydrogen, but which, when for some time in contact with water, is decomposed into carbonic-acid gas and sulphureted hydrogen, according to the formula $COS + H_2O = CO_2 + H_2S$. In mineral waters at the springs carbon-oxide-sulphide occurs; the analysis shows it as carbonic-acid gas and sulphureted hydrogen.

"There is a further reason for thinking that minimal quantities of substances in mineral waters may be of importance. The salt mixture forms a whole from which no part can be taken away without disturb-

ing the equilibrium. This shows the fallacy of the old-fashioned notion that springs, the chief ingredients of which are the same, have the same therapeutic effect even though differing in some minor ingredients. There is no analysis so exact or sensitive as our senses—taste and smell. A perfume of musk in the air is perceived by the smell even though it can not be demonstrated by chemical analysis. Even the best manufactured artificial mineral waters differ from the natural ones in taste and value. This difference is not easy to explain. It is sometimes found, however, that the two mineral waters, otherwise identical, differ as regards electrical conductivity.

"As to the so-called 'indifferent' springs, it is a mistake to speak of them as of minor value. It must be remembered that they too contain mineral ingredients, if only in minimal quantities, which counteract the harmful properties of perfectly pure distilled water. Even hydropathy is a mineral-water treatment, for if the water used were without traces of mineral substances it would be poisonous. This has been sufficiently proved elsewhere."

To Contributors and Correspondents.—*The attention of all who purpose favoring us with communications is respectfully called to the following:*

Authors of articles intended for publication under the head of "original contributions" are respectfully informed that, in accepting such articles, we always do so with the understanding that the following conditions are to be observed: (1) when a manuscript is sent to this journal, a similar manuscript or any abstract thereof must not be or have been sent to any other periodical, unless we are specially notified of the fact at the time the article is sent to us; (2) accepted articles are subject to the customary rules of editorial revision, and will be published as promptly as our other engagements will admit of—we can not engage to publish an article in any specified issue; (3) any conditions which an author wishes complied with must be distinctly stated in a communication accompanying the manuscript, and no new conditions can be considered after the manuscript has been put into the type-setters' hands. We are often constrained to decline articles which, although they may be creditable to their authors, are not suitable for publication in this journal, either because they are too long, or are loaded with tabular matter or prolix histories of cases, or deal with subjects of little interest to the medical profession at large. We can not enter into any correspondence concerning our reasons for declining an article.

All letters, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication. No attention will be paid to anonymous communications. Hereafter, correspondents asking for information that we are capable of giving, and that can properly be given in this journal, will be answered by number, a private communication being previously sent to each correspondent informing him under what number the answer to his note is to be looked for. All communications not intended for publication under the author's name are treated as strictly confidential. We can not give advice to laymen as to particular cases or recommend individual practitioners.

Secretaries of medical societies will confer a favor by keeping us informed of the dates of their societies' regular meetings. Brief notifications of matters that are expected to come up at particular meetings will be inserted when they are received in time.

Newspapers and other publications containing matter which the person sending them desires to bring to our notice should be marked. Members of the profession who send us information of matters of interest to our readers will be considered as doing them and us a favor, and, if the space at our command admits of it, we shall take pleasure in inserting the substance of such communications.

All communications intended for the editor should be addressed to him in care of the publishers.

All communications relating to the business of the journal should be addressed to the publishers.

Contributors who wish to order REPRINTS of their articles should do so on a blank prepared for that purpose, which will be sent to them by the publishers on receipt of a request to that effect. The order should be sent to the publishers, and not to the editor.

Original Communications.

FURTHER EXPERIENCES WITH DIRECT ELECTRIZATION OF THE STOMACH.

By MAX EINHORN, M. D.,

PHYSICIAN TO THE GERMAN DISPENSARY AND
INSTRUCTOR IN CLINICAL MEDICINE
AT THE NEW YORK POST-GRADUATE MEDICAL SCHOOL.

IN my paper,* A New Method for Direct Electrization of the Stomach, I put much stress on the necessity of applying the electric current within the stomach—a fact which has been previously recognized by different authors. At the same time I devised a new method of direct electrization, which frees it of all the difficulties with which it has hitherto been connected. The novelty consists in that I employ a deglutable electrode. There is no need of my lingering on the *modus operandi*. The same is known to all of you, and is fully described in the paper mentioned.

About a year later I published another article, entitled Therapeutic Results of Direct Electrization of the Stomach;† the same contained several experimental investigations upon the effect of direct gastro-electrization on the gastric secretion in man, and besides a detailed description of all the cases I had treated by direct electrization of the stomach during eighteen months.

There were twenty-nine cases in which direct gastrofaradization had been applied, five in which first direct faradization and afterward direct galvanization of the stomach were administered, and one in which the galvanic current was given alone. The *résumé* of this paper was as follows:

"Direct gastrofaradization proves to be useful in many ways in most chronic diseases of the stomach. The favorable results appear very clearly and pretty quickly in those cases of stomach dilatation which are not caused by any obstruction of the pylorus, but merely by the relaxation of the muscular coat of the stomach. Here the gastrofaradization is beneficial, no matter whether in these cases there is hyperacidity or subacidity of the stomach contents. Cases of relaxation of the cardia (eructations), and also of relaxation of the pylorus (presence of bile secretion in the stomach), were very favorably influenced by faradization. Here the result was most markedly pronounced, inasmuch as, besides the subjective amelioration of the patient, the objective examination showed at the same time the absence of bile in the stomach contents (there was, however, only one case of relaxation of the pylorus under observation).

Direct gastrog galvanization was administered with very good results in cases of obstinate gastralgia; several of them had resisted every therapeutic means, but yielded to the influence of galvanization."

As I have mentioned in the above-quoted papers, the literature on the efficacy of direct gastro-electrization is very scanty—i. e., very few have been treated by this method. Stockton‡ is the only author who has treated a larger series of cases by direct gastrofaradization.

Since the publication of the two papers referred to on direct electrization of the stomach no experiences by other authors have thus far been communicated. Ewald* only mentions that he had very good results with direct gastrofaradization in two cases of ructus. This author recommends the same treatment in all those cases where the musculature of the stomach has to be strengthened. Ewald approves of the shape and form of my electrode, but mentions that he finds it difficult to get down into the patient's stomach. For this reason Ewald has modified my electrode by using a thicker rubber tubing around the wire; the tubing corresponds to No. 13 Charrière, and is about a millimetre and a half thick.

J. Ravé† has treated two cases of dyspepsia by direct gastrog galvanization, and speaks in favor of the deglutable electrode.

I must say that the insertion into the stomach of the deglutable electrode offers no difficulties. The principal point is to put the electrode far back into the pharynx and to let the patient meanwhile drink something. It is advisable to have the patient drink slowly about a glassful of water, and to have a talk with him, in order to detract his attention from the procedure. The electrode usually soon reaches the stomach, and it seldom happens that it remains lying in the fauces. If this does happen, the patient must eat a small piece of bread and drink some water; the electrode will then find its way into the stomach with the bread.

I have applied the deglutable electrode to more than a hundred people, and met with only one who was unable to swallow it. In this patient I had to use an electrode with a thicker rubber tubing (analogous to Ewald's modification) which could be pushed into the stomach. He, however, was a timid man, without any will power, who did not believe in his being able to do anything spontaneously. When told to swallow, his reply was, "I can not." In all other cases the deglutable electrode has been successfully applied. After the first application its insertion is much easier, the patient being accustomed to the procedure.

The principal advantage of the deglutable electrode consists, firstly, in that we are able to apply the method in people not used to the stomach tube, and, secondly, in that the thin cord does not cause any uncomfortable feeling to the patient during the entire electric sitting and does not provoke salivation. Another advantage lies in the circumstance that the deglutable electrode can be administered even in those cases in which ulcer of the stomach is suspected, whereas the old stomach electrode could not be introduced in them for fear of causing perforation.

By means of the deglutable electrode‡ a regular course

* C. A. Ewald. *Berliner klinische Wochenschrift*, 1892, Nos. 26 and 27.

† J. Ravé. *Contribution à l'étude du traitement des dyspepsies par l'électricité*, Paris, 1893. (Henri Jouve, Imprimeur de la Faculté de Médecine.)

‡ The attachment of the cord to the capsule of the deglutable electrode has been accomplished by Richard King & Co. (17 Park Place,

* Max Einhorn. *Medical Record*, May 9, 1891.

of electric treatment of the stomach becomes possible in many cases and is facilitated in all.

After these introductory remarks permit me to report my further experiences of direct electrization of the stomach gathered during the past year.

A. *In Reference to the Physiological Effect of Direct Gastro-electrization.*—In my previous papers I have proved by experiments that direct gastrofaradization ordinarily increases the secretion of gastric juice—i. e., there is found in the stomach a higher degree of acidity (caused by HCl) during electrization than at other times. The question arose whether this increased secretion of the stomach under the influence of electricity continues for some time after the application of the current. In order to decide this point the following experiments were made:

CASE I.—S. H., twenty years old.

1. *December 17, 1892.*—When fasting, drinks a glassful of water and swallows the electrode, which is left in the stomach for ten minutes and withdrawn, electricity not being applied. After forty minutes the stomach contents are obtained by means of a tube and examined: HCl +, acidity = 42.

2. *22d.*—When fasting, drinks a glassful of water and is gastrofaradized directly for ten minutes. Forty minutes after the drinking of the water the stomach contents are obtained and examined: HCl +, acidity = 52.

3. *25th.*—When fasting, drinks a glassful of water and is gastrogalvanized for ten minutes (negative pole in the stomach). Forty minutes after the partaking of the water the stomach contents are obtained and analyzed: HCl +, acidity = 20.

CASE II.—T. M., twenty four years old.

1. *January 10, 1893.*—When fasting, swallows the deglutable electrode and drinks a glassful of water. After ten minutes the electrode is withdrawn, electricity not having been applied. After half an hour the stomach contents are obtained and examined: HCl +, acidity = 14.

2. *12th.*—When fasting, drinks a glassful of water and is gastrofaradized (the deglutable electrode within the stomach) for ten minutes. Half an hour later the stomach contents are obtained and examined: HCl +, acidity = 18.

3. *24th.*—When fasting, drinks a glassful of water and is gastrogalvanized directly for eight minutes (the negative pole being in the stomach). After half an hour the stomach contents are obtained and examined: HCl +, acidity = 20.

CASE III.—C. H., twenty-three years old.

New York), the manufacturers of the instrument, in an excellent way. The cord is screwed into the capsule. The size and form of the electrode correspond with the accompanying figure.

1. *February 4, 1893.*—When fasting, swallows the deglutable electrode and drinks a glassful of water. After ten minutes the electrode is withdrawn, electricity not having been applied. After thirty-five minutes the stomach contents are obtained and examined: HCl +, acidity = 46.

2. *5th.*—When fasting, drinks a glassful of water and is gastrogalvanized directly for ten minutes. Thirty-five minutes later the stomach contents are obtained and examined: HCl +, acidity = 72.

From these experiments it seems that the electric action ordinarily increases the HCl secretion even during the first period after faradization.

How does the absorbent faculty of the stomach act immediately after electrization?

You all know that we are able to examine the absorbent faculty of the stomach by means of potassium iodide. The patient takes 0.2 of iodide of potassium in a gelatin capsule. The saliva is then tested by means of starch paper and nitric acid every minute or two. If the starch paper moistened in the saliva shows a slight violet or blue discoloration after the addition of a drop of nitric acid, then it indicates that the potassium iodide had been meanwhile partly absorbed from the stomach and eliminated through the saliva.

In order to see whether direct electrization of the stomach hastens the absorbent power of the same, the following experiment was conducted in like manner on several people: Firstly, the individual drank while fasting a glassful of water. After the lapse of ten minutes iodide of potassium 0.2 in a gelatin capsule and 20 c. c. of water were given. The saliva was examined every minute with starch paper and nitric acid and the result carefully noted. Secondly, about a week later the same individual while fasting drank a glassful of water and was treated with direct electrization of the stomach. After this iodide of potassium 0.2 in a gelatin capsule and 20 c. c. of water were given and the saliva examined as before. The results obtained in both trials (one without, the second with, electricity) can thus be compared and the influence of direct electrization studied.

Of the many uniform experiments made in this respect I shall report three as examples:

CASE I.—L. T., twenty-four years old.

1. *August 23, 1892.*—While fasting, drinks a glassful of water; ten minutes later he takes iodide of potassium 0.2 with 20 c. c. of water.

After 1 minute = no reaction.

" 2 minutes = " "

" 3 " = " "

" 4 " = " "

" 5 " = " "

" 6 " = " "

" 7 " = " "

" 8 " = + violet coloration.

2. *30th.*—When fasting, drinks a glassful of water and is gastrofaradized for ten minutes. He then takes iodide of potassium 0.2 with 20 c. c. of water.

After 1 minute = no reaction.

" 2 minutes = " "

" 3 " = " "

" 4 " = " "

" 5 " = " "

" 6 " = + traces.

" 7 " = + violet discoloration

CASE II.—Th. S., forty-four years old.

1. December 19, 1892.—When fasting, drinks a glassful of water. Ten minutes later he takes iodide of potassium 0.2 with 20 c. c. of water.

After 5 minutes = no reaction.

" 6 " = " "
 " 7 " = " "
 " 8 " = " "
 " 9 " = " "
 " 10 " = + traces.

I. TABLE OF CASES TREATED BY DIRECT GASTROFARADIZATION.

(From December, 1891, to December, 1892.)

No.	Name.	Age.	Disease.	Principal complaint.	How long sick before electrization.	How long treated.	Result of treatment.	REMARKS.
1	Robert P.	28 yrs.	Dilatation of the stomach, combined with hyperacidity.	Fullness, belching, crampy pains, diarrhoea.	About 3 yrs.	4 mos.	Disappearance of all symptoms.	
2	Murray F.	19 yrs.	Do.	Fullness, belching, pains, constipation, despondency.	About 3 yrs.	4 mos.	Greatly improved.	
3	Josef F.	27 yrs.	Do.	Bad taste, pains in the epigastrium, constipation.	About 2 yrs., with free intervals.	1 mo.	Disappearance of symptoms.	
4	Edward K.	63 yrs.	Do.	Belching, crampy pains, diarrhoea, weakness.	About 12 yrs.	3 mos.	Greatly improved.	
5	Aron L.	36 yrs.	Do.	Complete anorexia, weak feeling, constipation.	6 yrs.	3 mos.	Do.	
6	James G.	43 yrs.	Do.	Anorexia, pains after each meal, constipation.	5 yrs.	3 mos.	Disappearance of symptoms.	Eight pounds gained during treatment.
7	Benjamin B. W.	23 yrs.	Do.	Anorexia, pains, constipation.	1 yr.	3 mos.	Do.	Eleven pounds gained during treatment.
8	Johann St.	33 yrs.	Do.	Belching, constipation, burning sensation in the scrobiculum.	12 yrs.	1 mo.	Improved.	
9	Morris G.	24 yrs.	Do. Mitral insufficiency.	Anorexia, belching, pains, constipation.	2 yrs.	1 mo.	Greatly improved.	
10	Gustav K.	26 yrs.	Do. Mitral insufficiency.	Anorexia, belching, pains, weakness.	4 to 5 mos.	1 mo.	Do.	
11	Mrs. S. M.	About 30 yrs.	Hyperacidity.	Burning sensation in the scrobiculum, belching.	4 to 5 mos.	1 mo.	Disappearance of symptoms.	
12	Miss Stella B.	About 34 yrs.	Enterptosis combined with hyperacidity.	Do.	4 yrs.	6 wks.	Do.	There was real gastropotosis. <i>Ren mobilis dexter</i> . Patient before coming under my treatment had undergone for three months the meat and hot-water régime. She looked like a skeleton. After four weeks of the electric treatment, gained nineteen pounds.
13	Mrs. Pauline F.	43 yrs.	Do.	Inability to eat, burning sensation after meals, weakness.	2 yrs.	6 wks.	Do.	The gastrodiafrane shows the situation of the stomach between the navel (small curvature) and the symphysis pubis. <i>Ren mobilis dexter</i> .

TABLE OF CASES TREATED BY DIRECT GASTROFARADIZATION.—(Continued.)

No.	Name.	Age.	Disease.	Principal complaint.	How long sick before electrization.	How long treated.	Result of treatment.	REMARKS.
14	Mrs. Henrietta C.	45 yrs.	Enteroptosis combined with hyperacidity.	Anorexia, belching, constipation.	12 yrs.	Improved.	Real gastropptosis.
15	Mrs. Antonia B.	36 yrs.	Enteroptosis, gast. gland. chr.	Anorexia, burning sensation after meals, constipation.	5 yrs.	3 mos.	Disappearance of symptoms.	Eight pounds gained during treatment.
16	Mrs. Gussie W.	34 yrs.	Do.	Do.	4 yrs., with free intervals.	2 mos.	Do.	
17	Mrs. Editha Sch.	35 yrs.	Do.	Anorexia, uncomfortable after meals.	6 yrs.	2 mos.	Do.	
18	Carl Sch.	36 yrs.	Do.	Anorexia, burning sensation in the scrobiculus.	1 yr.	1 mo.	Do.	The examination of the stomach contents revealed after Ewald's test breakfast before undergoing the electric treatment no free HCl; two weeks later free HCl was present.
19	Walter C.	28 yrs.	Do.	Poor appetite, belching, bloated feeling in the abdomen.	8 mos.	2 mos.	Do.	Real gastropptosis (gastrodiaaphany).
20	Miss Meta Z.	About 30 yrs.	Gast. gland. chr.	Anorexia, heavy feeling in the chest after meals.	5 yrs.	3 mos.	Do.	<i>Ren mobilis dexter</i> . Has gained twelve pounds during treatment. First, no free HCl; afterward, HCl+.
21	Mrs. L. L. G.	About 40 yrs.	Do.	Anorexia, bad taste, belching, bloated feeling.	2 yrs.	3 mos.	Do.	The gastrodiaaphane shows the stomach one finger-width above the navel (small curvature), extending to about two to three finger-widths above the symphysis pubis. <i>Ren mobilis dexter</i> . In the beginning, no free HCl; afterward, HCl present.
22	Chs. H. Alb.	About 44 yrs.	Do.	Poor appetite, epigastric pains after meals.	1 yr.	2 mos.	Do.	Ten pounds gained.
23	Mrs. Cora A.	32 yrs.	Repeating; gast. gland. chr.	Aggravated belching, anorexia, pains.	5 yrs.	2 mos.	Do.	
24	Marx D.	43 yrs.	Do.	Aggravated belching, bulimia, vertigo.	3 mos.	3 wks.	Do.	
25	Aron L.	50 yrs.	Atonia cardiae et pylori; dilat. ventriculi.	Vomiting, belching, severe gastralgia.	5 yrs.	5 wks.	Do.	When fasting, the stomach contained at the beginning gastric juice and bile; after a while there was no admixture of bile, and later on no fluid, in the stomach when fasting. HCl was present all along.
26	Alfred K.	28 yrs.	Atonia gastro-intestinalis.	Belching, bloated feeling, diarrhoea.	About 1 yr.	2 mos.	Greatly improved.	In the beginning of the treatment one hour after the test breakfast there was no free HCl; after two weeks' treatment HCl was present in normal amount. Patient has gained four pounds.
27	Miss Jennie F.	30 yrs.	Dilatatio ventriculi.	Anorexia, gastralgia.	5 yrs.	3 mos.	Do.	
28	Johann C.	32 yrs.	Dilatatio ventriculi, hyperacidity.	Belching, poor appetite, often diarrhoea.	3 yrs.	6 wks.	Not much improved.	
29	Henry R.	40 yrs.	Dilatatio ventriculi, gast. gland. chr. Beginning atrophy.	Absolute anorexia, pains after meals.	4 yrs.	3 mos.	Improved.	Besides the stomach trouble there was a vitium cordis. One hour after the test breakfast there was never found free HCl; renet was present.
30	Harris B.	32 yrs.	Do.	Belching of a very offensive gas, occasionally vomiting.	6 yrs.	6 wks.	Do.	There was no free HCl present one hour after the test breakfast, although the acidity was high, caused by the presence of organic acids. After three weeks' treatment the belching disappeared, the organic acids were less, but free HCl could be detected only after faradization. Upon my advice the patient went South for further recreation.
31	George W. St.	62 yrs.	Anæmia pernicio-a? Gastralgia.	Constant pain in the scrobiculus.	1 yr.	3 wks.	Not improved.	

II. TABLE OF CASES FIRST TREATED BY DIRECT FARADIZATION, AND THEN BY DIRECT GALVANIZATION OF THE STOMACH.

(From December, 1891, to December, 1892.)

No.	Name.	Age.	Disease.	Principal complaints.	How long undergoing electric treatment.	How long gastro-faradized.	With what result.	How long gastro-galvanized.	Number of galvanic sittings.	Result of treatment.	REMARKS.
1	Theodor L.	19 yrs.	Dilatation of the stomach, hyperaciditas, mitral insufficiency.	Belching, severe pains after meals.	6 mos.	1 wk.	Belching disappeared, but the pains persisted.	16 d.	5	Disappearance of symptoms.	
2	Paul F.	33 yrs.	Dilatation of the stomach, erosions of the gastric mucosa; first heart sound not clear.	Continual severe pains in the epigastric region, vertigo occasionally.	1 yr.	2 wks.	Slight amelioration.	25 d.	7	Do.	The examination of the stomach contents one hour after the test breakfast before the electric treatment revealed <i>no free HCl</i> , and the acidity was only = 12. In the middle of the treatment free HCl was present, and the acidity = 28.
3	George V. Sk.	About 35 yrs.	Dilatation of the stomach, hyperaciditas.	Severe pains, weak feeling, inability to do much mental work.	2 yrs.	6 wks.	Greatly improved, but pains once in a while.	2 mos.	6	Do.	In the beginning of treatment, one hour after the test breakfast: HCl+, acidity = 104; at the end of treatment: HCl+, acidity = 88.
4	David H. H.	42 yrs.	Dilatation of the stomach, hyperaciditas, tabes dorsalis incipiens.	Severe gastralgia, poor appetite, weak feeling.	1 yr.	2 wks. and a half.	Improved very little.	2 wks.	3	The pains were less severe.	
5	Adolf F.	33 yrs.	Hypersecretio gastrica continua periodica, dilatation of the stomach, hyperaciditas.	Severe gastralgia, nausea and vomiting spells in the morning, sleeplessness.	2 yrs., with free intervals.	3 wks.	Greatly improved, no vomiting, pains less severe.	6 wks.	5	Disappearance of all symptoms.	The stomach contained when fasting, in the beginning of treatment, about 50 to 60 c. c. of gastric juice. After the third week of treatment it was empty in the fasting condition of the patient.
6	Charles D.	24 yrs.	Hyperaciditas, ructus.	Severe gastralgia, belching, burning sensation in the scrobiculus.	8 mos.	2 wks.	Improved, belching disappeared, less pains.	1 wk.	3	Improved, burning sensation less, only once in a while.	(The patient had to go back, on account of business, to his native city, New Orleans, and was obliged to stop the treatment.)
7	Edwin N. D.	32 yrs.	Gast. gland. chr., with beginning atrophy; dilatation of the stomach, mitral insufficiency.	Gastralgia, belching, weak feeling.	5 yrs.	1 wk.	Less belching, pains same as before.	4 wks.	8	Disappearance of all symptoms.	
8	Morris S.	43 yrs.	Hyperaciditas, weak heart, arteriosclerosis.	Fainting spells after meals, constant burning sensation in the epigastric region, gastralgia occasionally, constipation.	5 yrs.	4 d.	No effect whatever.	3 mos.	27	Disappearance of all symptoms.	

2. 15th.—While fasting, drinks a glassful of water, and is directly gastrofaradized for ten minutes. He then takes iodide of potassium 0.2 with 20 c. c. of water.

After 2 minutes = no reaction.

From these experiments it appears that the absorbent faculty of the stomach is increased by direct gastro-electrization (faradization or galvanization), a fact which hitherto, as far as I am aware, has not been experimentally proved by others.

B. *Experiences of the Therapeutic Effect of Direct Electrization of the Stomach.*—As I have already fully described in my last paper a large number of cases treated by direct gastro-electrization, I shall now refrain from a detailed description of different cases and shall limit myself to a brief report, giving in tables all the cases recently treated by this method.

All cases contained in the accompanying tables are those of private patients of mine who were treated by direct gastro-electrization with the deglutable electrode in the course of thirteen months (from the beginning of December, 1891, to the end of December, 1892). The time of electric treatment for each patient and all other necessary points are given in the tables.

Summary.—Thus there were forty-two patients treated by direct electrization of the stomach. Only in two no amelioration of the condition could be noticed; in all others there was either a complete disappearance of the subjective symptoms or at least a great amelioration of the same. Besides the subjective sensation of amelioration in the patients, in many cases there could be noticed at the same time a better appearance of the patient; in several cases an increase in weight was noticed and will be found reported in the tables. In those cases in which no mention is made of the weight in the tables, either the weight was the same as in the beginning of the treatment or the patients did not keep a record of it. In several cases an amelioration of the objective symptoms could be noticed—

III. TABLE OF CASES TREATED ONLY BY DIRECT GALVANIZATION OF THE STOMACH.

(From December, 1891, to December, 1892.)

No.	Name.	Age.	Disease.	Principal complaint.	How long sick before the electrization.	How long galvanized.	Number of sittings.	Result of treatment.	REMARKS.
1	Albert M.	34 yrs.	Enteroptosis, <i>ren mobilis dexter</i> , hyperaciditas, heart sounds not clear.	Severe gastralgia, fainting spells occasionally, constipation.	2 yrs., with free intervals.	2 mos.	12	Disappearance of all symptoms.	Six pounds gained during treatment.
2	Leonard S. R.	30 yrs.	Hyperaciditas.	Severe gastralgia.	3 mos.	5 wks.	12	Do.	Patient had undergone the galvanic treatment with very good result about a year previous to this attack. During last summer patient had much mental strain, and this was probably the cause of relapse.
3	Paul W.	42 yrs.	Gast. gland. chr., dilatation of the stomach, mitral insufficiency, dilatation and hypertrophy of the heart.	Gastralgia, palpitations of the heart, poor appetite, weakness.	About 2 yrs.	2 mos.	16	Do.	When beginning treatment, the pulse was intermittent; two weeks later, regular. The result of examination of stomach contents was previous to galvanic treatment: HCl ?, acidity = 24; one month later: HCl +, acidity = 80.

Table I contains thirty-one cases treated by direct gastrofaradization. In eighteen all subjective symptoms of sickness disappeared; in seven there was a great amelioration—*i. e.*, a subsidence of nearly all the symptoms; in four there was a noticeable improvement, and in the remaining two the condition of the patient remained unchanged.

Tables II and III contain merely cases with complaints of severe pains in the gastric region (gastralgia).

On Table II will be found those cases which were treated first by the faradaic and thereafter by the galvanic current. The galvanization was administered in these cases for the reason that faradization in some of them effected an improvement only, but no cure, and in some again no change whatever. The final results were very good. In six the gastralgia, as well as all other symptoms of disease, totally disappeared, and in the remaining two, in which the galvanic current had not been applied long enough (each of them had only three galvanic sittings), there was a marked amelioration.

In Table III three cases are reported in which galvanization alone was applied. In all these three cases the gastralgia was of an intense nature, and in two of them complicated with slight heart trouble. In all three cases the gastralgia disappeared.

i. e., the chemical analysis of the stomach contents showed an improvement of the condition. The references to these points will be found on the tables under the heading "Remarks."

After having discussed the main characteristics of the tables I would like to mention a few points in reference to the electric treatment. I gave to my patients the usual necessary drugs; a few only partook of no medicines whatever. I modified and prescribed diet only when necessary, and advised suitable hygienic measures accordingly.

I ordinarily applied the electrization every other day during the beginning of treatment; afterward—*i. e.*, after the lapse of two to three weeks—twice weekly for about three weeks, and thereafter once a week for some time. As a rule, I begin to decrease the frequency of the sittings when I notice a decided improvement in the condition of the patient. Even after a complete disappearance of the symptoms it is advisable to continue the electrization (once a week) for some time.

According to my belief, it is of importance to apply gastro-electrization upon a certain plan. Thus it will not appear superfluous to give a detailed description of the electric application I generally employ.

The patient, when having the deglutable electrode within

the stomach, opens his clothes, so that the abdomen is accessible. The key of the deglutible electrode is connected with the cord (negative pole) running to the battery.

Gastrofaradization.—Sitting, ten minutes; at first large plate electrode at the gastric and epigastric region for five minutes, then a small ordinary sponge electrode. The electrode is at first moved up and down from left to right in the gastric region (sometimes, principally when there is constipation, one goes with the electrode over the region of the colon—ascendens, transversum, and descendens—always beginning in the right iliac region and stopping at the left iliac region (duration, two minutes)); thereafter one proceeds from the gastric region from right to left to the back, and remains at the left side of the seventh dorsal vertebra for one minute. [At this place the current can be applied quite strongly, and most of the patients then experience a slight sensation within the stomach; the patients find it difficult to describe this sensation; some assert that they experience a dragging feeling, others a feeling of weight, and others again of pinching. All of them place this feeling within the stomach and locate it opposite different heights of the abdominal wall.] One then returns to the front, moving the electrode gently up and down over the gastric region for two minutes, gradually decreasing the current, and thus ends the sitting. The strength of the current has to be of such a nature that it causes distinct contractions of the abdominal walls; but it is not well to have the current so strong that the patient experiences pains.

Gastrogalvanization.—Negative pole within the stomach; small sponge electrode. Duration, eight minutes. First, two minutes below the ensiform process (during the first minute the current is gradually increased to its necessary strength); then for three minutes moving the electrode up and down the gastric region. After this, one then goes to the back and remains one minute at the left side of the seventh dorsal vertebra, returns to the front, moves the electrode around the gastric region for one minute, and remains then quietly for one minute below the ensiform process. During this time the current is gradually weakened and the sitting ended, the strength of the current being ordinarily fifteen to twenty milliamperes.

Before concluding this paper I should yet like to discuss a few points with regard to galvanization. I have already in my previous paper emphasized how effective this current is in gastralgia. Tables II and III seem to confirm this. The amelioration ordinarily appears by degrees and not suddenly. First, the pains are somewhat less severe, thereafter they begin to remain away for some time, and at the end they disappear completely. This gradual disappearance of the gastralgic pains seems to indicate that the beneficial effect must be ascribed to the galvanic current and not to mere suggestion.

Among the five cases of severe gastralgia, fully described in my previous article,* there were two with vitium cordis (cases Auguste K. and Th. G. H.). Among the eleven cases treated by galvanization, reported in this paper,

there are six with more or less distinct heart trouble. In all of them the galvanic current exerted a highly beneficial effect. Not only did the gastralgic pains disappear, but very frequently the heart action of the patient took a decided turn for the better. Thus, for instance, Patient Paul W. (Table III, 3), when beginning the galvanic treatment, had an accelerated and intermittent pulse; later on the same became normal as regards frequency and rhythm. Morris S. (Table II, 8) previous to treatment used frequently to suffer from fainting spells after meals; afterward these spells ceased.

It seems, therefore, that the galvanic treatment not only exerts a favorable influence upon the stomach, but that it has a tonic effect upon the heart. According to my opinion, it would be justifiable to give the galvanic treatment a trial in some affections of the heart, even if they are not complicated with gastric disorders. Perhaps they could be treated by the same method of galvanization—i. e., having the negative pole within the stomach. Under all circumstances, however, I would advise administering the galvanic current in every case of gastralgia complicated with affections of the heart.

As a *résumé* of this paper permit me to submit the following conclusions:

A. *Regarding Physiology.*—1. Direct gastrofaradization ordinarily increases gastric secretion, even during the first period after electrization.

2. The absorbent faculty of the stomach is considerably accelerated directly after the gastro-electrization (faradization and galvanization).

B. *Therapeutically.*—1. Direct gastro-electrization is a potent agent in the field of chronic (non-malignant) diseases of the stomach.

2. Gastrofaradization appears especially useful in most cases of dilatation of the stomach and enteroptosis; further, in atonic conditions of the cardia (ructus) and pylorus (presence of larger amounts of bile in the stomach), and in chronic gastric catarrh (gastritis chronica glandularis).

3. Gastrogalvanization is almost a sovereign means for combating severe and most obstinate gastralgias, no matter whether their origin is of a nervous nature or caused by a cicatrized ulcer of the stomach.

4. Gastrogalvanization exerts also a favorable influence on several affections of the heart complicated with gastralgia.

107 EAST SIXTY-FIFTH STREET.

THE CAUSATION OF INFLAMMATION.

A REVIEW.*

By HARRY FRIEDENWALD, A. B., M. D.,

LECTURER ON OPHTHALMOLOGY AND OTOTOLOGY,
COLLEGE OF PHYSICIANS AND SURGEONS, BALTIMORE.

IN surveying the works of ophthalmologists of recent years, it appeared to me that one, above all others, deserves the widest recognition and the most thoughtful attention.

* Read as the chairman's report of the Section in Ophthalmology, etc., before the Medical and Chirurgical Faculty of Maryland, April, 1893.

* *Loc. cit.*

The work I refer to is on *The Causation of Inflammation*, by Theodor Leber, professor of ophthalmology, formerly of Göttingen, now of Heidelberg.*

This work is the result of many years of labor. Portions of it have been published from time to time. Others besides Leber have been engaged at the same task. In this last published work the entire subject is reviewed and his results and those of others are considered in a thorough manner, known in German as *Kritik*. In my paper I shall not name the various authors, but confine myself to the report of some important facts and conclusions. Many of these are not new, but are familiar to pathologists; still their repetition may be of use. The experiments were made, for the most part, on the eyes of rabbits and other animals.

The eye possesses many advantages for observing the processes of inflammation. Its transparent media enable us to see the gradual and minute changes. Some of its tissues being non-vascular, reduces the complex processes of inflammation to the most simple terms. It has also been found that there is very slight danger of secondary infection after careful experiments on the eye.

The great work had its beginning in a very interesting and rare case. A countryman whose eye had been injured with chaff was attacked with suppurative keratitis. The necrotic corneal tissue was filled with a variety of *aspergillus* (*A. fumigatus*). Experiments showed that this fungus was capable of causing similar inflammation in the cornea of living rabbits, into which it was introduced.

These were the first experiments with pure cultures of fungi, and they proved that certain forms were capable of development in previously healthy animal tissues and of producing suppurative inflammation without the aid of bacteria. Further experiments proved that different fungi were very unlike in these properties or in the intensity of their action, some varieties being incapable of development at the body temperature, some finding the cornea and other tissues unsuitable soil. It has also been found that different organs are affected to a very varying extent by fungi injected into the blood-vessels, and that, moreover, different animals show greater or less predisposition to their action. Non-vascular tissues offer the best culture ground.

The introduction of pure cultures of *Aspergillus fumigatus* into the cornea is followed by keratitis manifesting itself the next day. There is some conjunctivitis, which gradually increases, and the corneal wound is slightly infiltrated. The infiltration, at first limited to the corneal wound, gradually increases in density and size, and the epithelial covering is lost. The peripheral part of the cornea becomes somewhat hazy. About this time (third or fourth day or later) a crescentic or circular infiltration rapidly appears around the primary lesion. This is opaque, sharply defined, especially on its inner border, narrow, and stationary. Its outer border passes over into the diffuse haziness of the periphery of the cornea. Between the circular infiltration and the central lesion there is a larger or

smaller area which at first is perfectly or almost clear. Later on the central infiltration increases and reaches the circular zone, and the epithelial layer within this area is lost.

In the mean time there is considerable exudation in the anterior chamber, beginning with a deposit upon the inner surface of the cornea beneath the primary infiltration, frequently similar to the circular corneal infiltration, but somewhat smaller, and a fibrinous deposit on the margin of the pupil and in the pupillary opening. On the anterior surface of the iris, especially below and at the bottom of the anterior chamber, there is a purifibrinous deposit.

The growth of the fungus is limited to the area inclosed in the circular zone, which acts as a line of demarcation; with few exceptions, the fungus did not enter the anterior chamber, Descemet's membrane offering too much resistance to its progress.

After five or six days the inflammation abated; at the same time there was a development of a vascular zone, spreading from the conjunctiva over the surface of the cornea and sometimes extending to the circular infiltration. The area within the circular zone, which has become purulent and softened, is thrown off either entire, causing perforation of the cornea, or partially in some milder cases, producing a deep ulcer, and this is followed by cicatrization.

If we now follow the fate of the fungi which were introduced into the corneal substance either in the form of spores or of a developed mycelium, we find that they rapidly grow through the corneal substance in all directions, without any relation to its structure, forming a mycelium especially dense at the border of the growth. The growth is, however, as already stated, always limited to the area inclosed by the circular infiltration.

The minute changes in the cornea are no less interesting than those visible to the naked eye. The first consist in a loss of the epithelium and the endothelium above and below the growth and a superficial infiltration of leucocytes under the margin of the epithelial defect—to a slight depth—and in the epithelial layer near the margin. Rarely are they found entering along the fungous threads or even surrounding them. The periphery of the cornea is infiltrated with leucocytes; they are densest at the edge of the cornea and gradually diminish toward the center. The circular infiltration likewise consists of leucocytes, which here are closely packed between the fibers of the corneal tissue. In this zone they are so closely placed that their edges can not be seen, but at the margin they appear drawn out and distorted in their efforts to enter the narrow spaces. At the inner edge of the zone the infiltration suddenly ceases and neither leucocytes nor even corneal corpuscles are to be seen within. The zone of infiltration usually pervades all the layers; sometimes it does not reach the deepest one, and then it is seen to become closer in the deeper layers and perhaps, forming a continuous layer, surround the central infiltration from behind.

Besides the infiltration of leucocytes, there is an exudation of fibrin into the conjunctival and subconjunctival tissue about the cornea and into the cornea to the circular infiltration.

* Die Entstehung der Entzündung und die Wirkung der Entzündungs-
erregenden Schädlichkeiten nach vorzugsweise am Auge. Angestellten
Untersuchungen von Dr. Theodor Leber. Leipzig, 1891.

There is also an abundant production of pus and fibrin in the aqueous humor. It is important to remember that this purulent collection in the anterior chamber is formed very early—long before the fungous growth has reached the deepest layers of the cornea.

The iris and ciliary body show some infiltration with leucocytes, mostly on the anterior surface of the iris (nearest the cornea), and especially prominent near the angle of the anterior chamber.

In the further course the fungi are found to cease growing and the central area becomes more and more infiltrated with pus corpuscles. In these areas the corneal structure disappears entirely, and even the fungi are destroyed. The subsequent steps were mentioned above. In the mildest cases, in which the spores did not germinate at all or only very late, the inflammatory symptoms were very much slighter, but they were always present. In these cases there was an abundant infiltration of leucocytes where the spores had been introduced, and these were either filled with spores or were spread along the course of the developed threads in the form of a cloak. In a short time the enveloped threads could not be found, having been destroyed by the leucocytes. The spores which did not germinate gradually disappeared. The reason for the great difference in their action from those described above lay in their retarded development.

I have described this form of inflammation so minutely because I shall have to revert to it, and I shall be able to avoid lengthy descriptions in other forms by referring to this.

In the anterior chamber the *Aspergillus fumigatus* produced violent inflammation, but it developed a mycelium only in the membrane of Descemet of the cornea and in the anterior capsule of the lens. In the latter situation it produced no evident inflammatory reaction within the lens; the only change consisted in necrosis of the lenticular epithelial cells. The growths on the cornea produced a dense infiltration of leucocytes in the deep layers of the cornea corresponding to the part of Descemet's membrane affected. There was absolutely no growth of the fungus on the iris. This was covered with a thick layer of fibrinous exudation. In other words, the fact may be stated that the fungus develops in non-vascular tissues, but that it can not grow on those that are vascular. In the vitreous there was abundant development of the growth with violent symptoms of inflammation; the purulent infiltration extended to the retina and even into the anterior chamber. As in the cases of corneal infection, it was seen that the effects went far beyond the limits of the growth itself.

Leaving the class of the fungi and passing over to certain bacteria, we find that the introduction of pure cultures into the cornea produces symptoms very similar to those described above, due to the aspergillus, and that they also are capable of development in this soil. The early appearance of purulent exudation in the anterior chamber, besides other signs, shows that bacterial inflammation also spreads beyond the area occupied by the bacteria. It is especially interesting to note that this purulent collection, known as *hypopyon*, is free from germs, and is therefore due only indirectly to their presence in the cornea. It is

also important to learn that the leucocytes forming the collection are not derived from the corneal infiltration at all, as is usually believed, but from the neighboring vascular parts—the iris and ciliary body. The consideration of the changes constituting the foregoing forms of inflammation has shown that within a definite area around the growths there is necrosis of the tissue elements, and that beyond this there is infiltration with leucocytes.

In the corneal inflammations it was seen that the infiltration was twofold: firstly, slight infiltration beginning in the wound, and, secondly, an intense infiltration in the form of a limiting circle. Both depend upon the migration of leucocytes into the cornea, the former being derived from the contents of the conjunctival sac, the latter from the vascular tissues surrounding the cornea. In cases of slowly growing fungi the central infiltration may exist alone and become so great as to surround the separate threads of the growth in the form of a mantle.

The only explanation for the extensive action of micro-organisms is, that they produce by their growth certain soluble, diffusible, and poisonous substances, which in more concentrated forms produce necrosis of the tissue where they are formed, and which, reaching the neighboring blood-vessels in more diluted amounts and acting upon them, cause inflammatory hyperæmia, exudation, and emigration of leucocytes.

It was evident that the leucocytes were attracted toward the seat of the micro-organisms. In the cornea this was very apparent in the area between the periphery and the circular zone of infiltration. The reason that they proceeded no further than the circular band of infiltration—indeed, the reason that this band was formed—lay in the fact that here the concentration of the poison became too great and paralyzed them.

In these experiments the question arises as to what prevents the growth and the continued spread of the organisms. It was found under certain circumstances, especially when the inflammatory action was slight, that micrococci and spores found their way into the interior of the leucocytes. This is due to a process known as *phagocytosis*—the taking up by leucocytes of small particles into their interior. How much this process interferes with the progress of the micro-organisms can not be stated, but it is probable that it is not important. Perhaps the reason lies in some property of the inflammatory exudate that is detrimental to their growth.

It is to the leucocytes that the most important work must be ascribed—namely, that of forming the line of demarcation and of separating the necrotic portion and causing it to be thrown off.

The experiments on the effects of the introduction of micro-organisms into various parts of the eye were followed by another series to determine the results of the introduction of their chemical extracts. Extracts of fungi, even of some which in themselves are incapable of producing any considerable inflammation, cause necrosis of a larger or smaller area of tissue and purulent infiltration beyond it. The same can be said of extracts of putrefied substances. The inflammation in these cases is similar to that produced by living organisms, but is less intense, owing to the

fact that but small quantities could be introduced, that they were rapidly absorbed, and that they were not reproduced as they are when the living organisms lie in the tissues. Injections of boiled *Staphylococcus aureus* into the anterior chamber are followed by the most intense inflammation. But the course differs markedly from that produced by similar injections of the living organisms. The latter is a progressive inflammation which gradually destroys the whole eyeball. The former intense inflammation subsides after a certain time and ends in complete healing. Whenever the amount of injected material was sufficient, the inflammation was accompanied by the rapid production of a large perforation of the sclerotic coat at the angle of the anterior chamber. This was due, it is believed, to the constant filtration through the angle of the anterior chamber and the consequently greater action of the poison at this part. There was a large amount of puriform exudation in the anterior chamber, often filling the entire cavity, but hypopyon was found only in the most severe cases. (In these cases, too, the entire cornea became anæsthetic.) And yet, as stated above, this condition would pass away with absorption of all or of most of the exudation, and finally even a return of the transparency of the cornea. (This was preceded by vascularization of its periphery and a subsequent disappearance of the blood-vessels.)

The separation of the active chemical substance in solution from the boiled micrococci was a very difficult problem, but was finally solved. From the solution the dried crystalline substance was at last obtained. It is known as *phlogosin*. This substance causes necrosis and intense inflammation even of the uninjured conjunctiva. Introduced into the anterior chamber, it produced the most violent inflammation within a few hours, extending to the conjunctiva and even the eyelids.

Accepting the fact that the inflammatory action of micro-organisms depends upon chemical substances which they produce, the next question that arises is whether other chemical substances have like properties. It is not long since it was denied that chemical substances could produce suppurative inflammation. This was based upon the results of injections of certain substances, such as croton oil, which in most cases produced inflammatory œdema and exudation of fibrin only; though I wish to mention here that our former fellow-townsmen, Professor Councilman, had shown that under proper conditions sterilized croton oil would produce suppuration. Furthermore, we must bear in mind that there is no essential difference between suppurative and non-suppurative inflammation. In both there is emigration of leucocytes, and suppuration depends only upon its degree.

Among the many chemical substances examined were various metals, such as iron, copper, mercury, lead, silver, gold; besides these there were glass, carbon, arsenious acid, etc., of inorganic substances, and organic substances, such as croton oil, oil of turpentine, cantharidin, jequirity, indigo, uric acid, etc., and finally oil, starch, and parts of animal tissues. These were introduced into the anterior chamber (either directly or inserted in minute glass

tubes, open at one end), into the vitreous, and into the cornea.

In all cases it was shown that the substances were pure and free from bacteria, and the eyes were afterward examined carefully to determine that no subsequent infection had occurred. Each substance seemed to act in a manner peculiar to itself. But all caused greater or less inflammation. It is impossible to give even an abstract of all these experiments. I shall confine myself to the results obtained in a very few, which will serve as examples, and to the general conclusions.

The introduction of sterile mercury was followed by suppurative exudation without considerable inflammatory reaction. I need scarcely repeat that in all experiments there were numerous examinations, which showed that there was no infection. About twelve hours after a drop of mercury was injected into the anterior chamber it was covered with pus. The purulent collection gradually increased. The cornea later on became vascular in that part where the purulent mass lay against it. Finally the cornea became purulent and softened at some point; perforation would occur, and the anterior chamber would be emptied of its contents. Then recovery took place. Injected into the cornea in fine globules, it was found to produce severe inflammatory reaction. The globules were surrounded by a purulent deposit, and in one case where the drop was larger there was a distinct circular infiltration.

Bits of sterilized copper introduced into the anterior chamber acted in a similar manner. Suppuration began in about fifteen hours; but this involved only the part occupied by the foreign body. The rest of the iris was apparently normal. In a few days the collection of pus would reach the upper margin of the pupil. There was vascularization of the cornea, which finally covered the part over the purulent collection. If the anterior chamber was emptied, the symptoms would rapidly subside and recovery would take place. If not, there would be spontaneous diminution of the inflammation. The purulent collection would decrease. The corneal and conjunctival congestion would disappear, but the foreign body would usually work its way gradually out through the cornea. Copper acted in a very curious way when introduced partly into the lens so as not to be in contact with the vascular iris. In this case it produced very slight reaction. It was subsequently found that the action of copper was violent only when in contact with vascular tissue.

As an example of another mode of action let me refer to the experiments with arsenious acid. This produced extensive necrosis, but only slight suppurative reaction, and this at quite a distance from the seat of operation. Gradually as the acid became absorbed the infiltration came nearer. It was evident that the substance acted in a poisonous manner upon leucocytes even at a great distance. Introduced into the anterior chamber, it was seen almost unchanged for several days, without any infiltration or scarcely any fibrinous exudation in its neighborhood. After several days only was there beginning suppurative exudation, and this occurred on the opposite side of the iris at the most distant point; later on there was exudation nearer the body.

In order to show the action of what are considered inert

substances let me mention that of gold. In the anterior chamber pieces of gold produced no effect visible to the naked eye; but even after a few weeks the microscopic examination revealed proliferation of the endothelium, the formation of giant cells, and emigration of leucocytes. In the vitreous the effects were still more evident.

Having demonstrated that the above chemical substances, both the active and those otherwise considered inert, produce inflammation of different degrees and of different kinds, we are led to inquire in what manner and by what means this is accomplished. As in the case of inflammation due to micro-organisms, it was found that these substances showed effects through a much larger space than that they occupied—in other words, that they acted at a distance. This forces us to the conclusion that they must become partly dissolved in the animal fluids, and pass by diffusion to the neighboring parts. This could be directly proved in certain cases, as, for instance, with copper; it was demonstrated that neighboring tissues contained traces of this metal. Substances which are usually considered insoluble—such as gold, silver, glass—likewise show distant action, and the conclusion stated before can not be denied. They must be soluble to a very slight degree, and, furthermore, very small quantities of these solutions must suffice to produce inflammation. Solutions of mercury, copper, or lead salts are very poisonous, while iron is found as a normal ingredient in the animal body. The first metals named are very slightly soluble in the animal fluids, while the latter is much more easily soluble. It is therefore very interesting to observe that the former excite considerable inflammation while the latter is almost harmless.

Oily substances which are insoluble in water are partly emulsified and are carried to neighboring parts in the form of fine particles. Whether in the form of an emulsion or of a solution, the above substances produce necrosis in their neighborhood and inflammatory reaction beyond by acting as irritants to the tissue elements. Substances which produce great inflammatory reaction must therefore be considered as cell poisons, which in weak concentration act as the excitants of inflammation.

Very inert substances act as excitants only and cause processes which lead to their elimination or encapsulation. It is conceivable that the various substances act in a different manner, and that this accounts for the differences in the forms of the inflammation produced.

A most interesting series of experiments consisted in the introduction of finely powdered substances into the anterior chamber and vitreous. They were either injected or placed in minute glass tubes and thus inserted. Among the substances experimented with were gold, platinum, cinnabar, sulphate of barium, and pure powdered carbon. In all the cases there was greater or less emigration of leucocytes from a distance, and the fine particles were partly taken up into their interior. There was also increased exudation of fibrin.

It is not conceivable that these substances acted purely in a mechanical way, for their action did not confine itself to their immediate neighborhood. Furthermore, the little tubes which contained these substances became filled to a greater or less extent with pus cells, while empty tubes pro-

duced but the slightest reaction. The action of the powdered substances, as in the case of gold, was much more intense than that of the solid pieces.

Leber holds that here too we must consider it a chemical action, and that these substances are not absolutely insoluble; and also that their solubility is increased by being in the form of powder, which has an infinitely greater surface exposed than the solid substances. The greatest difficulty which this view encounters is in the case of pure carbon; Leber is unable to give any hypothesis for its solubility. I would venture the hypothesis that the surface attraction of this substance may account for its action.

Leber's work offers further strong proof of the truth of Cohnheim's theory, that pus cells are derived by emigration from neighboring vessels. I can not refrain from citing certain experiments which bear strongly on this point, and show conclusively that the tissue cells are of secondary importance in the formation of pus. He introduced dead sterile corneas into the abdomen of rabbits. Some of these corneas were first injected with small amounts of sterile putrefactive fluid, just, as mentioned above, had been done with living eyes. Those that contained this inflammation-producing fluid showed the same characteristic forms of purulent infiltration when taken out of the abdomen as described above—slight infiltration at the seat of injection and a ring of infiltration at a definite distance from it. The non-injected dead corneas when taken out of the rabbit's belly showed but slight general infiltration, as would have been expected, for these also act as foreign bodies. The experiment was made additionally instructive by the fact that most pus cells of the circular infiltration contained pigment granules which were derived from the narrow pigment zone found around the cornea, which had been taken up in their course through this part. The pus cells of the central infiltration were entirely free, and this showed that they had come from without directly into this part without traversing the periphery.

According to Leber, the same attraction which brings leucocytes from a distance causes them to surround the fine particles and to take them into their interior, the process mentioned above as *phagocytosis*. In this action various powdered substances are not at all equal. The whole process by which the leucocytes are attracted through chemical irritation he terms *chemotaxis*.

THE PREVENTION OF SEPSIS IN THE PRACTICE OF MIDWIFERY.*

BY FRANCIS M. BANTA, M. D.

THAT to which I desire to call your attention is a few suggestions relative to the prevention of sepsis in the practice of midwifery, and especially the midwifery of private practice, the conditions as found in the hospital being so widely different as practically to call for separate consideration.

* Read at the bimonthly meeting of the Alumni Association of the Medical Staff of the Northern Dispensary, May 17, 1893.

In a large maternity hospital the rules are formulated and printed; the doctors, nurses, and assistants, who are obliged to conform to them, are educated, skillful, and scrupulously cleanly. The following are a few of the rules and methods of treatment now in use at the Sloane Maternity Hospital, an institution that of its first thousand patients lost one through sepsis, and there is reason to believe that she was infected before entering the hospital. The details of the aseptic and antiseptic measures there employed are quoted at some length from the report of Dr. McLane, because, while admirable and instructive in themselves, they may be taken as representing with small changes those employed in most of the large lying-in hospitals at the present day:

In this institution "the bath rooms, sinks, and water-closets are removed as far as possible from the wards and special delivery rooms. Patients awaiting confinement are separated from the puerperal women. Each patient on entering the hospital is obliged to take a full bath under the supervision of a nurse, plenty of soap being used, and special attention given to the hair, which is thoroughly shampooed with larkspur or ether or both, or, if very dirty, with bichloride solution. A vaginal douche of bichloride (1 to 5,000) is given and a rectal enema of soapsuds. The woman is then attired in clean clothes, the property of the hospital, her own garments being placed in a bath and subjected to a heat of 250° F. in a small room specially designed for the purpose, and afterward stored in a locker in the basement. The lying-in wards are used in rotation, and after being occupied by four patients are thoroughly cleaned, the furniture washed with a solution of carbolic acid, and left unoccupied with open windows for several days. Special delivery rooms are employed, situated conveniently to the wards. Each room is provided with a table of special design, upon which all deliveries take place. The bedding is protected by water-proof paper, which has been found an excellent substitute for the ordinary India-rubber sheet. Fountain syringes are employed to give injections; the glass nozzles attached to the soft-rubber tubing when not in use are kept in jars containing a solution of bichloride. When a patient is taken in labor she is transferred from the waiting ward to the delivery room, where a vaginal douche and rectal enema are given early in the first stage.

"Chloroform is given when necessary in the latter part of the second stage—to the obstetrical, not the surgical degree. The placenta is expressed by the Credé method at the end of fifteen minutes, one drachm of the fluid extract of ergot then administered, a vaginal douche of three pints of bichloride solution (1 to 5,000) of a temperature of 116° F. given, and the uterus held for one hour after delivery, when, if well contracted, the binder is applied, the patient placed upon another table, which is provided with wheels, and removed to the ward where she is to remain during the puerperium. The perineum, if torn to any extent, is sutured at once with silk-worm gut. The intra-uterine douche is only given in cases of instrumental delivery or where the hand has been introduced.

"The entrance to the genital canal is closed by an antiseptic pad, twenty-eight inches long and eight inches wide,

made of gauze and filled with absorbent cotton. On the first day these pads are changed every four hours, on subsequent days once in eight hours, the pads being somewhat smaller as the lochial discharge diminishes in quantity. No visitors are allowed in the wards. Patients and nurses wear only clothes that can be washed, and the physicians sack coats of white duck. All soiled articles of clothing and bedding are put in bags and at once sent to the laundry in the basement by means of a copper chute, the opening being in the hall near the wards and covered by a small iron door. Physicians and nurses exercise the most scrupulous care in regard to personal cleanliness and disinfection. Before making a vaginal examination the hands are scrubbed and a nail brush is used; they are then immersed in alcohol and afterward in a solution of bichloride (1 to 2,000). Alboline kept underneath a bichloride solution is used as an emollient. No sponges are allowed in the hospital, being replaced by absorbent cotton."

How different are the circumstances under which the general practitioner is called upon to treat a case of midwifery! From the first he is often confronted with such a mass of uncleanness, ignorance, and incompetency on the part of nurse, relatives, and patients as to make his efforts in combating sepsis a wearisome task.

The nurse, who is often a relative, seems in many instances to be chosen for the office because of the number of children she has borne, and frequently performs the house work in connection with her nursing duties. Often she is a veritable Mrs. Gamp, and, like her, possesses "rules and regulations" of her own, "which" (as she expresses it) "can not be broke through." The directions of the physician seem to her like so many efforts on his part to add to her already long list of duties, and they are either openly or furtively disobeyed or only obeyed in part. To insist upon even personal cleanliness of patient and nurse is too often a signal for open rebellion.

The room is generally the smallest, darkest, and most uncleanly of those occupied by the family, seldom large enough to permit of approaching the bed excepting from one side, and suspended from its walls is a motley assortment of clothing in various stages of disintegration; the bed, often an ancient structure and the scene of many a confinement, will not permit of being moved about, and is covered with old rags, carpet, and blankets.

The patient, if she is a primipara, is traveling an unknown path in a strange country, and in the first stage of labor is usually found in a mental condition that makes her oblivious to everything save her pains. She has engaged her physician and nurse, and there she considers her responsibility ends. Bichloride or carbolic-acid solutions, an adequate supply of clean linen, absorbent cotton pads, toweling, or even soap and water are sometimes difficult to obtain, and if the subject has not been discussed previously, and precautions taken to procure the articles required before labor pains have commenced, it is often-times too late to secure them afterward.

The foregoing is briefly what is frequently encountered by most of us who practice midwifery in this city, especially among those who live in the tenements. These were the cir-

circumstances under which many of the patients were born, and the mother or aunt, who too often acts as chief counselor, is only reproducing that which was found sufficient preparation in her own labors.

What is needed among these people is a more thorough appreciation of the necessity of making the proper preparation for what should be regarded as a surgical case. No time should be lost by the physician retained in a case of midwifery in visiting the patient's residence and acquainting himself with the character of her surroundings. A written list of the articles she is required to furnish should be given her.

The lying-in room should be the largest, pleasantest, and best ventilated of those at the disposal of the family. Provision should also be made for light, no unimportant matter when it comes to stitching the ruptured surfaces of a perinæum. All superfluous hangings and furniture should be removed. The walls and woodwork should be well cleaned, the carpet removed, and the room well aired, especially during the week preceding confinement.

The bed should be cleansed and placed in a position to make it accessible from all sides. If possible, have a cot prepared especially for the confinement, from which the woman can be removed to her bed at the end of labor. In any case, arrange for a clean bed, and, what is equally important, arrange to have it kept so. This is not to be accomplished without a certain amount of systematic care and vigilance on the part of both nurse and physician. To secure this, no complicated or expensive apparatus is required. For a number of years I have used with much satisfaction absorbent pads, composed of sheet cotton, quilted thickly between layers of cheese cloth. These may be sterilized and covered with antiseptic gauze. When soiled, they should be burned immediately. They are inexpensive, much cheaper than the rubber obstetrical pads recommended by Kelly, nearly saving their cost in laundry work, and doing away with the miscellaneous collection of old rags, carpets, and oilcloth so frequently met with.

The nurse should be the best that can be procured. Of course, trained nurses are to be preferred, but they are not always available. Their wages are too high for the poor of the tenements, and the restricted space and other conditions under which these people often live are scarcely such as to tempt a modest and cleanly woman to take up her abode among them. In any case the woman chosen as nurse should be seen previous to the confinement, her references examined, and her qualifications ascertained. When it is considered that upon their strict obedience and cleanliness depends, in a great measure, the safety of the patient and the reputation of the physician, we can not be too careful in securing the best material possible to assist us. It would be well if physicians practicing midwifery among the tenements were to secure a list of names of a number of women who, for a modest consideration, would be willing to act as nurses in confinement. They would gradually become acquainted with his methods and with the importance of observing the precautions to be taken against the occurrence of sepsis, and serve generally as valuable coadjutors.

At the onset of labor give an enema to empty the lower bowel, wash the external genitals thoroughly with soap and water, and then bathe in an antiseptic solution. Whether or not to use a vaginal disinfectant douche before delivery is still a mooted question. There can be no doubt, however, that frequent and strong douches have an injurious effect upon the vaginal epithelium; also that the cases of toxic enteritis reported by Frankel, Peabody, Garrigues, and others have owed their origin to the strong bichloride solutions employed.

They may be classed as meddlesome midwifery. Lately Garrigues has suggested creolin as a substitute for corrosive sublimate in vaginal and intra-uterine douches. It is used in a half-per-cent. and a one-per-cent. strength, and is supposed to combine the three valuable qualities of being a lubricant, an antiseptic, and a hæmostatic, besides being innocuous, even if used internally in large doses.

After the child is born, no vaginal or intra-uterine douches should be given excepting in cases requiring the introduction of the hand or of an instrument into the vagina or uterus. As few as possible vaginal examinations should be made. Recently Crédé, Winckel, and others have urged that they should not be made in ordinary cases, and that we should rely for our knowledge of the progress of labor on abdominal palpation and the patient's groans.

This I believe to be an extreme precaution, and if the other details for the prevention of infection are used it is believed to be unnecessary.

After the birth of the child the placenta should be expressed by the Crédé method. This procedure has stood the test of time. It seems to be based on sound physiological principles, and holds a place in the system of the most successful of the lying-in institutions of the world.

Lusk describes it as "consisting essentially in applying, at first, light, and afterward stronger friction to the fundus of the uterus until an energetic contraction is obtained; at its height the uterus is grasped so that the fundus rests in the palm of the hand, with the fingers to the front."

Although this procedure is theoretically a very popular one, in practice I do not believe it to be employed as frequently as it should be. To grasp the uterus immediately after the birth of the child and to make powerful and unremitting pressure downward, as I have often witnessed, is not the Crédé method.

When it is properly performed, retention of the placenta is a rare occurrence; and if a safe degree of contraction is maintained for an hour longer we shall guard against hæmorrhage and the formation of clots, and diminish the severity of the multipara's after-pains. What is equally important, we shall prevent one of the most common sources of infection—retained clots, placenta, or membranes.

On pressure being removed from the uterus, remove the soiled absorbent pad, wash the external parts with bichloride solution, and repair any laceration of the vulva or perinæum that requires it.

As to the advisability of applying an occlusion dressing, opinion seems to be pretty evenly divided. That it is not

a necessity is shown from the results obtained in large lying-in hospitals, such as that at Vienna, which are as good as any. It is, however, received well by the patients, may have a favorable effect where other precautions in regard to cleanliness have been neglected, is a deodorizer, and is well adapted for use among the poor by excluding dirt that might otherwise enter the genital canal from the surrounding bedclothes.

The physician in attendance should observe the most scrupulous cleanliness as to hands, finger nails, clothing, and instruments. Before making vaginal examinations the hands and finger nails should be well washed and scrubbed with soap and water, then dipped in alcohol, and afterward in a solution of bichloride. All instruments used should be boiled and afterward placed in a solution of carbolic acid (1 to 20), or of creolin if preferred. Care should be exercised that the nozzles of syringes and the catheters and sutures employed are aseptic. In passing the catheter, see that no mucus is conveyed from the vulva into the bladder. This is only to be accomplished by thoroughly exposing the parts, cleansing the meatus with absorbent cotton, and dipping the catheter in bichloride solution before using it.

I have attempted to present a brief statement of a few of the difficulties and disadvantages under which the practitioner labors who attempts asepsis and antiseptis in the midwifery of private practice, and to make a few suggestions relating thereto.

Now and again we meet with those who tell us of a large experience in confinements without an instance of death from puerperal septicæmia, and this without employing any of the precautions detailed above.

In answer to them I have this to say: Fatality from sepsis is only one of its results. There is a long list of other consequences which follow, scarcely less to be dreaded than death, resulting in chronic invalidism and indescribable misery. Ask the pain-stricken women who apply to our hospitals and clinics for relief, How long have you suffered? How frequently it dates from a miscarriage or confinement!

I believe that much of this misery could have been prevented, and through the very methods detailed here; that those who neglect these precautions in the light of our present knowledge are recreant to their trust and duty, and that the day is not far distant when they can be held for malpractice.

Though the phenomena of normal labor are to a great extent physiological, yet there occurs in every labor more or less of the pathological.

As a recent writer has expressed it, "a woman during or after labor is a wounded woman."

50 JANE STREET.

An Honorary Degree.—The University of Alabama has conferred the honorary degree of master of arts on Dr. James K. Crook, of New York.

Harvard University.—It is reported that Dr. Henry W. Williams, the ophthalmologist, has announced his intention of giving the sum of \$26,000 for the endowment of a professorship of ophthalmology.

THE CAUSE AND TREATMENT OF MANY CASES OF VERTIGO, HEADACHE, AND OTHER NERVOUS DISORDERS.*

By F. C. HEATH, A. M., M. D.,
INDIANAPOLIS, IND.

The general practitioner meets with many obscure and puzzling cases, and nowhere more frequently than in the domain of nervous disorders. Scientific and satisfactory treatment of such cases requires careful investigation of their causation. The neurologist, gynecologist, oculist, aurist, rhinologist, and rectal specialist seek to aid him with records and explanations of reflexes from diseases in their special lines, sometimes perhaps a little overdrawn, but all containing at least a nucleus of truth.

Careful and honest observers will doubtless admit that there is no more frequent source of these reflexes than eye troubles, and it is this phase of the subject that I wish to consider with you briefly, in as plain a manner as possible and with careful avoidance of the technicalities of the specialist. Headaches and other nervous disorders due to errors of refraction (especially hyperopia or "farsightedness," and astigmatism or unequal refraction in different meridians) have been brought before the profession so fully and frequently that I will not now dwell upon this side of the subject further than to express the opinion that here is the source of by far the greater number of frontal headaches and sick headaches, besides a large share of attacks of dizziness and other functional nervous troubles.

But we must look to the muscles moving the eyeball for many cases, and here we enter a field of much uncertainty and disagreement. Roosa and Bull represent one extreme, teaching that the muscles should be let alone, while Stevens, the oculist, and Ranney, the neurologist, find nearly all nervous reflexes in cases of insufficiency of one or more of the eye muscles. The truth probably lies between these extremes, as the great majority of the better class of oculists and neurologists hold to day.

The symptoms arising from this form of eye strain are headache, especially in the *back of the head* and sometimes extending down the neck to the shoulder, less frequently temporal and frontal, sick headache, constant headache, crawling sensations, feeling of pressure or tight band across forehead or vertex; loss of power of attention, concentration, or self-control; indefinite fear, *dizziness*, amounting at times to *vertigo*, confusion of vision, letters chasing each other, tendency to nausea; numbness in fingers and arms, insomnia, nervous prostration, symptoms of hysteria or hypochondria, and (according to some authorities) epilepsy, chorea, melancholia, and other forms of insanity.

The production of these symptoms is accounted for in this way: Nature strives to make us see one object when looking with both eyes. To accomplish this, both eyes must *fix* the object—*i. e.*, the visual lines (drawn from the macula or point of most acute vision through the center of rotation of each eye) must be directed to the object—otherwise there will be double vision, as any one can easily prove to his own

* Read before the State Medical Society of Indiana, May 12, 1893.

satisfaction by pressing lightly over one lid while looking at anything steadily. These visual lines are practically parallel when looking at distant objects, but become more and more convergent as the object approaches the eye. It will thus be seen that the position of our visual lines is constantly changing, and that these changes require frequent action of the six muscles upon the outside of each eyeball. While these are so well balanced normally that the adjustments are easily made, whenever any muscle is relatively weak, it requires a special effort to fix the eye properly and muscular eyestrain is likely to be developed—so much extra nerve force being consumed that the patient suffers from one or more of the reflexes named. In neurotic subjects slight insufficiencies may produce annoying symptoms, and the extreme cases reported are probably confined to this class of unfortunate beings, many of whom must be content with nothing better than partial relief of troubles, even with the best skill attainable.

It has been suggested that some of these disorders are not reflexes, but the result of central lesions produced by constant peripheral irritation, and this *might* furnish an explanation why the removal of the original cause (the muscular insufficiency) may fail to cure the disorder.

There are several ways of detecting this insufficiency or weakness of the eye muscles, and I usually employ more than one to be doubly certain of obtaining a correct result. I will mention but one, the simplest, easiest, and least painful to the patient—viz., the Maddox rod test. Holding this rod vertically before one eye and looking at a light, you will see a horizontal streak of light with this eye and the flame with the other; if the rod be held horizontally, the light streak will be perpendicular. When the muscles are in equilibrium the streak passes through the middle of the flame, but in weakness of one of the vertical muscles the horizontal streak will be above or below the center of the flame. In weakness of either of the lateral muscles the perpendicular streak will be to the right or left of the flame. The degree is shown by the number of the prism required to cause the streak to pass through the flame.

The treatment of muscular insufficiencies and the reflexes arising from them consists in—

I. Promoting the general vigor and removing all unfavorable complications. This includes judicious exercise, proper diet, sufficient sleep, rest from overwork, general tonics, etc., with special attention to the nervous system and upper air passages.

II. Special treatment for the eyes.

1. Correct error of refraction, if any.
2. Strengthen the weak muscle by systematic exercise with prisms or limited and regular periods of reading with stereoscope or abducting prisms, or
3. Aid the weak muscle by prisms (or decentered lenses) to be worn either constantly or for near work only.
4. Rest for overtaxed eyes and eye muscles, in some cases even enforced rest by the prolonged use of atropine and dark glasses.
5. A progressive course of strychnine, if muscles supplied by third nerve are involved; use of *cannabis indica*, *belladonna*, bromides, antipyrine, etc., if the weakness be

in the external recti, supplied by the sixth nerve. Galvanism may be tried in either class of cases. We may also add the local use (in the eyes) of eserine or pilocarpine in cases of the first class, of atropine and other mydriatics in those of the second, while both are relieved by douching or spraying the eyes with cold water or mild lotions and applying stimulating liniments to the forehead and temples.

6. Operative treatment—either partial or graduated tenotomies of the stronger muscles (method of Stevens and Ranney), or, what seems more scientific, a complete tenotomy, regulating the effect by a suture (method of Noyes, Webster, Thompson, and the better men generally). Sometimes advancement of the weaker muscle may be tried.

I desire to enter a plea for conservative treatment in these cases, giving a few reasons and citing a few cases from which some lessons may be learned.

I. The eye muscles are not stable, varying in power from day to day.

Their strength depends largely upon the general condition, amount of exercise, fatigue, hours of sleep, sexual habits, refractive error and its correction, etc. To illustrate, one of my cases showed, February 10th, half a degree of vertical error, half a degree of weakness of external recti; February 18th, no vertical error, but half a degree of weakness of internal recti; March 6th, equilibrium. Another, February 14th, two degrees of insufficiency of internal recti; March 2d, half a degree of the same. A third, January 9th, one degree of vertical error and one degree of external; February 9th, none at all. A fourth, December 14th, two degrees of insufficiency of internal recti; February 11th, equilibrium; March 18th, half a degree of insufficiency of external recti.

Snipping the muscles might have done much harm here, perhaps producing some of the very troubles said to be due to muscular insufficiencies.

II. It is difficult, if not impossible, to regulate the effect of an operation. We may get too much or too little, sometimes none at all. Roosa refers to patients having double vision produced by tenotomies. Davis shows that, in the only one of Ranney's cases fully recorded, the muscles show the same strength some weeks subsequent to the operation as before, and thinks that probably true of the others, which result is at least a very disappointing return for the trouble and expense incurred. We should expect nothing more from graduated or partial tenotomies except occasional relief of spasm.*

III. The effect of the refractive errors must first be thoroughly understood.

An error of refraction being often the cause of a muscular insufficiency, correction of the former frequently relieves the symptoms due to the latter, as the following cases from my records show:

* Since writing the above an able article has appeared on this subject in the *New York Medical Journal*, April 15, 1893, by Dr. F. W. Marlow, of Syracuse, who is the first and only one (I think) to show that ocular muscles are sometimes weaker months after a partial tenotomy; but his mode of operating is different from that of Stevens and Ranney, and far more rational.

CASE I.—J. C. D., a sufferer from headache. Examination revealed astigmatism and insufficiency of internal recti. Corrected astigmatism only. After two months reports perfect relief.

CASE II.—Miss M. W., Lebanon. Pain in back of head, etc. Found 1 D. hyperopia under atropine and insufficiency of internal recti. Corrected one half the hyperopia only. After two months she writes: "Eyes growing stronger; no pains in back of head."

CASE III.—Miss M. B., bookkeeper. Slight dizziness, pains through temples, less often frontal and occipital. External recti weak, also right inferior rectus. A low degree of astigmatism. Corrected latter with perfect relief.

The presumption in these cases is that the muscular insufficiencies disappeared after correcting the errors of refraction, but, owing to the impossibility of getting another examination at the time relief was reported, this can not be proved. The following cases, however, show that symptoms usually attributed to the muscles must be due sometimes to the refractive trouble solely, the glasses correcting the hyperopia and astigmatism having caused disappearance of symptoms while the muscular insufficiency remained about the same:

CASE IV.—Miss H., attending Insane Hospital. Complained of dizziness and neuralgia in the eyes, temples, and back of head. Found and corrected astigmatism as follows: R. E. + 1.50 D. ax. 100° ; L. E. + 1.50 D. ax. 80° . Insufficiency of vertical muscles half a degree, and of internal recti two degrees for distance and eight degrees for near work, were found but not corrected. At last report, four months later, the dizziness and neuralgia had disappeared, but the insufficiency remained the same.

CASE V.—T. R., schoolboy. Constant headache, frequent dizziness, etc. Found hyperopia and insufficiency of internal recti. Corrected the former with marked improvement, the insufficiency remaining unchanged.

IV. It is practically impossible to be certain of the diagnosis in some cases.

What seems to be the relation of cause and effect between an insufficiency and certain symptoms may prove to be only a coincidence, as the following case well illustrates:

CASE VI.—Dr. F., for whom I had prescribed glasses correcting his slight hyperopia, presbyopia, and astigmatism six months before, appeared in January with vertigo or dizziness, difficulty in concentration of mind, etc.—the very picture of muscular insufficiency, as given in the writings of Seguin, Hotz, and others. Examination showed one degree of vertical insufficiency, half a degree of external recti. Prisms were added to glasses worn, half a degree base down right eye, half a degree base up left eye. They failed to relieve. After one month's use, equilibrium of muscles was found, with no relief of symptoms, showing that the symptoms were not a reflex from muscular insufficiency. Attention was next given to his ears as a possible source of the dizziness, but the symptoms continued after removal of cerumen and recovery from an otitis externa of right ear. A functional heart trouble has since been determined upon (partly by exclusion) as the probable cause of the dizziness. How grave an error would a tenotomy of the ocular muscles have been in this case!

V. Somewhat akin to the preceding is the difficulty of differentiating between cause and effect in some cases of

nervous prostration, especially with insufficiency of one or more eye muscles, since we have found that the latter may develop after the onset of the former or may give rise to it.

VI. The good results reported by operators are often due to other things than the operation. Glasses are prescribed in nearly all of the cases, and it is not unreasonable to suppose that they are entitled to credit for a large share of the benefits reported. In some other cases it may be merely *suggestion*, as Davis shows of one of Ranney's cases—undoubtedly a case of hysteria. The miraculous results here are about on a par with those of Christian scientists and clairvoyants in the same line.

VII. Some patients are neurotic by birth, as Roosa says, and will never get anything but palliation. Cure of such cases is out of the question. Having recognized cases as almost certainly of this class, radical treatment is hardly justifiable.

VIII. Some cases show weakness of all the muscles. Obviously operation here is not to be thought of.

IX (and lastly). Simple measures relieve the majority of cases.

We have seen the good results of correcting the errors of refraction. A recent case of mine was much benefited by taking a ten days' hunting trip. Cases VII, VIII, and IX show the results of prisms worn for near work only.

CASE VII.—F. L. C., Earlham College student. Headache, eyestrain, and inability to study. Refraction apparently normal, insufficiency of internal recti. Ordered prisms one degree, base in, for each eye for near work. Three months later reported perfect relief.

CASE VIII.—W. T., medical student. Subject to "bilious headache." Head and eyes feel bad after much reading, also after going to theater, etc. No apparent refractive error, but two degrees of insufficiency of internal recti for distance and five degrees for near point. Ordered for reading prisms two degrees, base in, for each eye. After one month reports entire relief.

CASE IX.—Mrs. R. L. G., Bloomington. Subject to headache from childhood. Past year much pain in back of head. Found hyperopia and three degrees of insufficiency of internal recti. Ordered for reading correction of manifest hyperopia, together with prisms one degree and a half, base in, for each eye, with *immediate* relief—whether permanent or not, we can not say, having had no further report.

Cases X and XI show the effect of prisms worn constantly in the more serious and less tractable variety of insufficiency—that of the external recti.

CASE X.—Miss P., nurse. Pain in head, especially back of head and neck. Astigmatism and five degrees of insufficiency of external recti. Ordered for each eye + 1.50 D. cyl. ax. 90° , with prism two degrees, base out. After one month's constant use reports relief, especially to pain in back of head and neck.

CASE XI.—Mrs. F. M. H. Extremely nervous. Frontal headache. Found myopia, astigmatism, and weakness of external recti. Corrected astigmatism and half of myopia, with no relief. Added prisms, base out, half a degree right eye, one degree left, with very marked improvement.

I wish to cite just one more case showing what I consider the most rational and satisfactory method of treating insufficiency of internal recti when patient will faithfully persist:

CASE XII.—Mrs. C. M. Frequent dizziness, drawing feeling in eyes, etc. Says she had one spell of "falling unconscious." Found insufficiency of internal recti, but no refractive error until late in the treatment, when a slight astigmatism was revealed under atropine. One oculist had performed four tenotomies (probably graduated or partial) on her external recti without improvement. Small doses of strychnine, with prism practice two or three times a week for two months, effected a practical cure, the insufficiency almost entirely disappearing, and no disagreeable symptom remaining, except occasional spots before the eyes.

In conclusion, let me not be understood as affirming that operative treatment is *never* advisable in insufficiencies of the ocular muscles, but that it should only be resorted to when the insufficiency and symptoms attributed to it persist, when the diagnosis is reasonably certain, when the patient is not hopelessly neurotic, and when all the more conservative measures above mentioned have been tried and found wanting.

A CASE OF
DERMOID CYST OF THE RIGHT OVARY,
FOLLOWED BY
GANGRENE OF THE FALLOPIAN TUBE AND OVARY,
CAUSED BY A TWISTED PEDICLE.

By R. EMMETT GIFFEN, M.D.,

COLONEL AND SURGEON GENERAL, NATIONAL GUARD, NEBRASKA;
SURGEON IN CHIEF OF ST. ELIZABETH HOSPITAL, LINCOLN, NEBRASKA.

In reviewing the literature of ovarian tumors I find but one case mentioned—that by Thornton—of gangrene caused by twisting of the pedicle. And there is some doubt in that case from the fact that it followed surgical interference. In the case I am about to report there was no surgical interference until the patient was placed on the operating-table.

Maggie S., aged twenty-eight, multipara, single, was admitted into St. Elizabeth Hospital August 8, 1892, in the medical department, suffering from pain in the lower part of the abdomen. Temperature, 102°; tympanites, etc. Five days later she was transferred to my department. I obtained from her the following history: She had always enjoyed fair health up to five years ago; she had a child at that time. One year after had gonorrhœa, followed by so-called "inflammation of the bowels"; was confined to bed for six weeks. For one year after that, with the exception of during her menstrual period, she was rather free from pain. For the past three years has suffered continually from pain in the right side, especially while at work, her occupation being that of a domestic. About a year ago she says that she felt a lump in the right groin, and while at stool it broke, and she passed considerable pus by the vagina, and continued to pass pus at intervals up to within a few days of her admission into the hospital.

At that time, while in the act of lifting a bedstead, she felt something that seemed to turn in the right side, and she was seized with the most excruciating pains in the right side and in the uterus and vagina, as if something was pulling the rectum and vagina. I saw her five days after her admission, and eight days after, as she termed it, her injury.

I examined her and found an enlarged tube and a cyst of the right annexa with abscess, and advised abdominal section. My wish was readily complied with, and on the following day, assisted by Dr. Britt, Dr. Grimes, and Dr. Beebe, I opened the

abdomen (it is understood that in all my operations everything is rendered thoroughly aseptic) and found a twisted pedicle, twice round, of the Fallopian tube, of a blackish-gray appearance, and so friable that in attempting to lift it up it tore to pieces, although the slightest force was used. I then enlarged the opening in the abdominal wall and passed my hand down into the pelvic cavity and found a cyst with a pedicle attached to the vaginal wall and twisted in like manner to the one attached to the uterus. I separated it from the vaginal wall, knowing the opening in the vagina would be a good point to drain through.

After removing the tube and ovary of the opposite side, there being a cyst of about the size of an egg in the left ovary, I washed the peritoneal cavity out thoroughly with hot water, put a drainage-tube through the opening in the vagina, and closed the abdomen. First of all, let me say that I always sew the peritoneum separately with a fine catgut continuous suture, then the muscular tissue in like manner, then use the interrupted suture, involving all the tissues save the peritoneum.

The patient rallied from the effects of the operation satisfactorily, and that night, while the nurse was absent from the room for a few moments, she got up out of bed, walked across the room, and, picking up a pitcher of water, drank copiously. Of course, the result was an attack of vomiting, which lasted several hours. On the following day her temperature was 101° F., and she complained of gas in her abdomen, which continued for five days, in spite of all remedies used. Her temperature never reached a point higher than that of the second day. I removed the drainage-tube on the third day. She continued to improve, on the fifteenth day after the operation was sitting up, and on the twenty-first day left the hospital feeling quite well. On opening the cyst, I found it to be a dermoid cyst, full of pus, with an opening in the twisted pedicle at the lower end—the one that communicated with the vagina. It also contained a piece of bone, a tooth, and a bunch of hair. The gangrene involved the Fallopian tube and part of the ovary. The cause of the gangrene can very readily be explained by the passage of air through the opening into the vagina to the abscess in the cyst, then the twisting of the pedicle by the turning of the cyst, cutting off all blood supply.

The Pan-American Medical Congress Excursion to Rome.—It has been definitely determined that the Pan-American Medical Congress Excursion to the Eleventh International Medical Congress will sail on the steamship Werra from New York on September 9th, the day following the adjournment of the congress at Washington, and will arrive at Genoa on September 20th, four days before the opening of the Rome meeting. Round-trip steamer tickets may be procured for \$142.50 for inside rooms, and \$150 and upward for outside rooms. Tickets are good for members of the congress and their families, and may be used at the option of the holder to return on any steamer of the line from Genoa, or on Saturday steamers from Bremen, or Sunday steamers from Southampton, during the months of October, November, and December. Physicians desiring to avail themselves of this exceptionally low rate should at once become members of the Pan-American Medical Congress by sending the registration fee (\$10) to the treasurer, Dr. A. M. Owen, Evansville, Ind., and informing the secretary-general, Dr. C. A. L. Reed, Cincinnati, of their intention to join the excursion. Passage should be secured without delay, as the trip, involving as it will a stop at the Azores and Gibraltar and a sixty hours' sail along the picturesque coasts of Spain, France, and Italy, promises to be very popular. Many prominent European guests of the Pan-American Congress will return on this occasion. The time allowed will afford American physicians an opportunity not only to attend the International Congress and visit Rome, but to extend their journey to the famous sanatoria of southern France and the Riviera.

NEW YORK, SATURDAY, JULY 8, 1893.

IMPROVED PREPARATIONS OF COCAINE.

THE *Pharmacological Record* for June treats of the latest improved forms of cocaine. The chemists of Germany seem especially constant in their endeavors to make the older drugs purer and better, no less than to develop new ones. This is eminently true of cocaine, now nearly ten years old in ophthalmic medicine, and its allies. According to Helbing, there are few preparations more liable than this group of drugs to varying degrees of purity, as found in commerce, and at the same time there are few in regard to which a definite and reliable physiological action is more urgently demanded. The preparations of the firm of Boehringer, of Waldorf, are prominent in this study, and they are found to be of an improved character and of an exemplary freedom from impurity. Cocaine hydrochloride continues to hold the first place as a local anæsthetic. The higher degree of purity existing to-day is discernible in the fact that Niemann's formula for cocaine—namely, $C_{17}H_{21}NO_4$ —has of late been found to need revision, and is now written $C_{17}H_{21}NO_4$. This new formulation is in part due to the fact that the best products of the best laboratories are marked by a notably increased freedom from uncombined ecgonine and from compounds of ecgonine other than benzoyl-ecgonine methyl ether as well as from those grosser impurities that find their way into or accompany nearly all our organic drug compounds. In addition to the hydrochloride, the other salts of cocaine that entered into this study in the *Record* were the nitrate and the hydrobromide, both of which answered well to the physical and chemical tests employed.

A new form of cocaine, called "dextrococaine," and its salt, the hydrochloride, is made the subject of a brief explanation by the investigator, regarding the method of their production. The optical activity of ecgonine and cocaine is a physical property common to organic bodies containing an asymmetrical carbon atom, being due to the effect of internal molecular motion on the rays of polarized light. Such optically active bodies, like tartaric acid, exist under two modifications, rotating to the right and to the left respectively. When the ordinary laboratory ecgonine or its derivatives are subjected to the action of strong caustic alkalis for several hours, a dextro-modification takes place, and dextro-ecgonine can be isolated from the product. This has the same chemical constitution as ordinary ecgonine, but behaves differently with the polarized ray; and it yields, under benzoylation and methylation, a cocaine that is likewise dextrorotary. This dextrococaine has an analogous physiological action to that of the ordinary (laboratory) cocaine, but is somewhat more rapid in its action and has

been found to cause a greater degree of local irritation than the older drug.

Still another new preparation, called "tropacocaine," derived from the narrow-leaved Java coca, is made by Boehringer, also its hydrochloride. The formula of this base reads $C_{15}H_{19}NO_2$. Although this drug has anæsthetic properties in common with cocaine, it is not mydriatic, and is reported by Liebreich and Chadbourne as being considerably less toxic. The solutions of the hydrochloride of tropacocaine have the advantage of high relative stability, and have been commended for dental purposes by Hugenschmidt, and for local anæsthesia, where marked and prompt action is desired, by Liebreich.

The conscientiously thorough work that has been done by the best cocaine manufacturers has greatly improved the therapeutic relations of that drug. "The difficulty of purification," says Helbing, "presented by the presence of various uncrystallizable substances," or amorphous bases that were too common in the cocaine of commerce a few years back, "could not have been overcome by any purely technical processes of the rule-of-thumb order. It was only by patient investigation pursued in the unwearying spirit of the scientific method, that the maker of cocaine has been able to obtain the high standard of purity that can be affirmed of the preparations we have been considering."

MINOR PARAGRAPHS.

THE EVENING WORLD'S CORPS OF FREE PHYSICIANS.

THIS corps was organized in 1889 for the purpose of caring during the summer months for neglected sick children who could not leave the city, or required medical attention before and after they had been taken to the country by the charities organized for that purpose, and it seems now to have become one of our permanent institutions. Its original plan of work was similar to that of the summer corps of the board of health, but its scope is much greater. Several physicians are employed to visit from house to house during the warm weather in search of neglected sick children, and to supply to them the care they need. The word care is to be interpreted in its broadest sense. It does not mean simply to prescribe medicine to be obtained at the neighboring apothecary's or to visit the child daily or oftener as may be needed, though these form a very important part of the physician's duties, but the needed changes are made as far as possible in food and hygienic surroundings. The food of a mother with a nursing child is made nutritious; clean, fresh cribs are furnished the little patients when required; if necessary, nurses are provided; and every effort is made to carry out whatever line of treatment seems best to the physician. While the purpose of the work is purely that of aid to the children, a suffering adult is not passed by—neglected sickness is cared for wherever it is found—but these persons are usually referred to hospitals and dispensaries if they require continued treatment. Cases of utter destitution are also temporarily relieved with food, and help is given, when possible, in obtaining work. Rent is never paid unless under exceptional circumstances. All these expenses are paid out of the fund subscribed for that purpose to the *Evening World*. The great amount of work done can be learned from the final report of the season of 1892, in which 207,188 visits were made, 16,495 patients treated, and 457 persons furnished with

clothing, 741 with food, and 2,400 with medicine. This year the corps began its labors on the 1st of June. Its members are all physicians who have had previous service and have proved themselves capable and judicious men, and it deserves recognition and support as one of the best and most efficient medical charitable organizations in the city.

THE TREATMENT OF URETHRAL STRICTURE BY ELECTROLYSIS.

ACCORDING to the *Medical Week* for June 23d, Dr. Reynier read a paper at a recent meeting of the Paris Surgical Society in which he stated that, out of eight cases of urethral stricture in which he had tried the electrolytic method, in two the treatment had had to be abandoned and internal urethrotomy performed instead, while in three others the desired result had been obtained only after two or three applications. In five cases electrolysis had been followed by a chill, in one by the formation of an abscess on the dorsum of the penis, and in two by lymphangitis. Currents of from fifteen to twenty milliamperes had always failed to relax the stricture, and comparatively powerful currents had been required to produce the required effect. The treatment had invariably produced pain that was but little modified by the previous application of cocaine. Dr. Reynier concluded that we were not justified in substituting electrolysis for internal urethrotomy, for, as now performed, that operation was usually devoid of risk.

CARDIAC POISONS OF MICROBIC ORIGIN.

DR. H. ROGER publishes a paper in the *Archives de physiologie* for April in which he states that his experiments show that sterilized cultures of the *Bacillus septicus putidus* contain toxins that act energetically on the frog's heart. These toxins are insoluble in alcohol. Their injection retards the action of the heart and increases the duration of the systole, and this effect may be prolonged for one or two seconds or even two seconds and a half. The arrest of the heart occurs in diastole, as in muscarine poisoning, but it occurs at a period when the beating is as energetic as normally, but becomes less and less frequent. The diastole may last from half a minute to a minute. Analogous results are obtained on living animals and on the isolated heart. During the continuance of the poisoning the heart can not be arrested by irritation of the pneumogastric, and it becomes equally insensible to faradaic currents acting directly upon the muscle.

A LINIMENT FOR EXCESSIVE SWEATING OF THE HANDS.

THE following formula is attributed to the *Journal des sciences médicales de Lille*: Borax and salicylic acid, each, fifteen parts; borie acid, four parts; glycerin and alcohol, each, sixty parts. The hands are to be rubbed with the liniment three times a day.

THE ONTARIO MEDICAL ASSOCIATION.

THE thirteenth annual meeting was held in Toronto on Wednesday and Thursday, June 21st and 22d. The attendance, although not so large as in some recent years, was quite good and the papers presented for discussion were fully up to the high standard of excellence for which the association is justly noted. The work done in the Sections in Medicine and Surgery was of a high character, and a series of frozen sections prepared in the anatomical department of Toronto University by

Dr. A. Primrose, with the assistance of Dr. F. N. G. Starr and Dr. A. R. Gardner, was a very interesting and instructive feature of the Section in Surgery. The proceedings of the association were gracefully and efficiently presided over by Dr. R. W. Hillary, of Aurora, who will be succeeded in the presidency by Dr. Laughlan McFarlane, of Toronto. The arrangement of the programme, both business and social, was in the hands of a very efficient and attentive committee, and to their efforts was due much of the success of the meeting.

ANTIPIRYNOMANIA.

UNDER this name Dr. Cappelletti (*Revista sperimentale di freniatria e di medicina legale*, March 31st; *Revue générale de clinique et de thérapeutique*, May 17th) writes of a mental affection caused by addiction to the use of antipyrine. An hysterical woman, twenty-three years old, had used the drug to excess for two years, to allay headache, taking every day as much as two drachms. She had become affected with loss of appetite, sleeplessness, tinnitus aurium, and muscular weakness. She entered a lunatic asylum of her own accord, to enable herself to abstain from antipyrine. The dose of the drug was reduced, but this produced such a state of prostration and such grave functional disturbances, even when the patient was unaware of the reduction, that potassium bromide and caffeine were resorted to. The patient was finally cured of these ill effects and of her craving for antipyrine. The author recommends the gradual reduction of the dose in such cases.

PHEDURETIN.

IN the May number of the *Centralblatt für die gesammte Therapie* there is a summary, from the *Pharmaceutische Post*, of an article on this new phenol derivative that has been brought forward by a Csestek apothecary named Orient. Mr. Orient describes pheduretin as forming fine, white, silky, acicular crystals that are tasteless, hardly soluble in cold water, and readily soluble in hot water. Its chemical constitution has not yet been determined with certainty. According to Mr. Orient's experiments on animals, it dissolves readily in the stomach and is absorbed into the blood within a short time. In large doses it appears to act upon the central nervous system and causes a profuse secretion of urine. A physician who has tried it in migraine is mentioned as having observed astonishingly good effects from it, coupled with its action as a powerful diuretic. The dose is from seven to fifteen grains, to be given twice a day.

A SNUFF FOR SUMMER CATARRH.

THE following formula is published in the *Correspondenzblatt für schweizer Aerzte*: Cocaine hydrochloride, one part; powdered camphor, two parts; bismuth subnitrate, sixteen parts.

ITEMS, ETC.

The Death of the Rev. E. P. Thwing, M. D., a medical missionary to Canton, China, has been reported by telegraph. Dr. Thwing's errand to China was largely in the interest of a proposed asylum for the insane, a form of hospital which had not hitherto found a foothold in that country. Dr. Thwing was regarded as the pioneer in that direction. He had been recently on a visit to his home in America, for the purpose of obtaining help for this object. Dr. Thwing was a native of Massachusetts. He was a graduate of the Andover Theological Seminary and of the Long Island College Hospital. Mrs. Thwing and two children are now in China, engaged in missionary work, and one of the

sons is a medical missionary in Alaska. Dr. Thwing's decease is said to have been due to typhoid fever, and it is thought that it was hastened by exhaustion consequent upon a prolonged nursing of his wife, who had been sick with the same disease.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending July 4, 1893:

DISEASES.	Week ending June 27.		Week ending July 4.	
	Cases.	Deaths.	Cases.	Deaths.
Typhus	6	2	0	1
Typhoid fever	19	6	17	5
Scarlet fever	66	12	74	9
Cerebro-spinal meningitis	4	2	7	6
Measles	214	15	159	17
Diphtheria	101	37	125	45
Small-pox	8	1	6	1

Army Intelligence.—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from June 25 to July 1, 1893:*

TAYLOR, MARCUS E., Captain and Assistant Surgeon, will, by direction of the President, report in person to the president of the Army Retiring Board at Fort Logan, Colorado, when required by the board for examination by it.

MERIWEATHER, FRANK T., First Lieutenant and Assistant Surgeon, is relieved from duty at Madison Barracks, New York, and ordered to Fort Logan, Colorado, for duty.

LA GARDE, LOUIS A., Captain and Assistant Surgeon, will, in addition to his present duties in connection with the World's Columbian Exposition, furnish the necessary medical attendance for the officers and enlisted men of the army on duty at the Exposition grounds.

SHANNON, WILLIAM C., Captain and Assistant Surgeon, in addition to his duties in the office of the Surgeon General, is assigned to duty as assistant to the Attending Surgeon in this city.

MATTHEWS, WASHINGTON, Major and Surgeon. The leave of absence granted is extended one month.

WALKER, FREEMAN V., Captain and Assistant Surgeon, now on leave of absence at the Army and Navy Hospital, Hot Springs, Arkansas, will proceed at once to Fort Trumbull, Connecticut, and report in person to the commanding officer of that post for temporary duty, relieving CRONKHITE, HENRY M., Major and Surgeon. Major Cronkhite, upon being relieved by Captain Walker, will proceed to Fort Clark, Texas, and report in person to the commanding officer for duty at that post.

STARK, ALEXANDER N., First Lieutenant and Assistant Surgeon, is relieved from duty at Fort Monroe, Virginia, and ordered to Fort Clark, Texas, for duty, relieving MEARNS, EDGAR A., Captain and Assistant Surgeon. Captain Mearns, upon being thus relieved, will proceed to Nogales, Arizona, and report to the senior member of the commission appointed for the location and marking of the boundary between Mexico and the United States, for duty with the commission.

Book Notices.

A Text-book of the Theory and Practice of Medicine. By American Teachers. Edited by WILLIAM PEPPER, M.D., LL.D., Provost and Professor of the Theory and Practice of Medicine and of Clinical Medicine in the University of Pennsylvania. In Two Volumes. Illustrated. Vol. I. Philadelphia: W. B. Saunders, 1893. Pp. xii-909.

DURING recent years there has been no lack or even scarcity of works on the practice of medicine, and among them there

have appeared several of unusual value and excellence. The medical profession, however, must always hail with satisfaction the addition of all good works to its literature. And especially is this true when the new work presents distinct advantage and marked superiority over its predecessors. Such is the case with the book edited by Dr. Pepper.

A mere inspection of the list of authors, including as it does many of the most prominent medical authorities of this country, is a sufficient indication of the excellence of the work, and this indication is amply confirmed by the consideration of the text. That the book is by American authorities only is particularly emphasized, and should be to us a source not only of satisfaction but of pride, for it compares to its great credit with similar works by foreign authors and justifies the statement made for it in the preface that it "may be said to represent truly the best teaching of the science and art of medicine at the present time in this country." It is undoubtedly one of the best text-books on the practice of medicine which we possess.

Hygiene is the first subject considered, and most ably but far too briefly for a subject so important. By its very excellence the chapter but increases the reader's appetite, which by its brevity it can not satisfy.

The fevers come next, and among them we wish to call particular attention to the article on typhoid fever, for as an example of what an article on a medical subject should be it is perfect. Complete, accurate, well arranged, and written in an easy, graceful, and most readable style (it is to be regretted that the last should be so rare a trait of medical literature), it is beyond criticism.

Then follow the contagious diseases and the exanthemata.

Twenty-three pages are devoted to syphilis. Now a knowledge of syphilis is in some degree necessary to every practitioner, and were a text-book on medicine the only book that physicians had they might well expect to find instruction on syphilis therein. But there are many works which more properly treat of this disease, and so important a subject can not be adequately discussed in twenty-three pages.

Leprosy also does not properly belong to general medicine, and yet three pages are given to it. The contagiousness of leprosy, we are aware, is open to dispute, but we must take exception to the author's statement that "the contagiousness of leprosy can not be doubted." The inclusion of actinomycosis is open to the same criticism, and of the disease might be said what the author himself says of the treatment—it "is almost entirely surgical."

The articles on anthrax, glanders, and foot and mouth disease might give rise to the same comment, but less justly, and certainly where a disease is on the debatable ground between two branches of medicine it is far wiser, for the sake of completeness, to suffer the accusation of commission rather than that of omission.

The volume is concluded by what is practically a separate work on diseases of the nervous system, so extensive and complete is it. Almost three hundred and fifty pages are devoted to the subject, and they are full of value. Especially noticeable here are the arrangement and grouping, always so important in a subject so complex.

Special features of the volume merit notice. References to authorities are frequent, but appear in the text, and the pages are not encumbered by a host of foot-notes which in a text-book serve but to distract the attention. Illustrations and charts are of sufficient number and excellent quality; several are unusually fine. The index is complete and well arranged.

The publisher, too, is to be congratulated upon the appearance of the volume. In paper, type, and binding it is in har-

July 8, 1898.]

money with the matter it contains, and all combine to make this work one of exceptional value.

Psychopathia Sexualis, with Especial Reference to Contrary Sexual Instinct: a Medico-legal Study. By Dr. R. von KRAFFT-EBING, Professor of Psychiatry and Neurology, University of Vienna. Authorized Translation of the Seventh Enlarged and Revised German Edition, by CHARLES GILBERT CHADDOCK, M. D., Professor of Nervous and Mental Diseases, Marion-Sims College of Medicine, St. Louis. Philadelphia: The F. A. Davis Co., 1893. Pp. 436.

This work will be a revelation to many because it shows that sexual vices and depravity, perhaps most familiar through the writings of Martial and other authors of the period of Roman decadence, are still prevalent in various parts of the world. There is no doubt that Dr. von Schrenck-Notzing's inference is correct, that the seven German editions of this work were largely attributable to a pornographic interest on the part of the public; and we believe also that the statement that sexual perversions are to the physician himself a *terra incognita* is largely true.

That von Krafft-Ebing has succeeded well in his purpose of describing the pathological manifestations of sexual life is demonstrated by the one hundred and ninety-two histories contained in the volume. He disclaims any intention of laying the foundation of a psychology of sexual life, and his attempt to refer the pathological manifestations of that life to underlying conditions is as incomplete as he feared it might be.

It is the experience of all physicians that have had charge of lunatic asylums that sexual anomalies are frequently one of the expressions of the cerebral disease. Where these anomalies are not symptomatic they are the expressions of vice, and, as Krafft-Ebing himself says, they are committed by sensual men who have become satiated or impotent from excessive indulgence in a normal way or by those that have masturbated.

The reader is likely to be fatigued by the details of numbers of similar clinical histories, and the chapter on therapy is not likely to give him more than a suggestion regarding the methods of treatment.

A work on what is if not a vice a symptom seems superfluous; and one might as well expect value from a monograph on "dropsy" as from one on sexual perversion. It is not to be believed that this work did in the original any more good than the numerous pamphlets on similar subjects distributed by quacks do; and the letters incorporated in the text from those into whose hands *Psychopathia Sexualis* has fallen savor of the testimonials not unfamiliar to American physicians. The volume will undoubtedly gratify the curiosity of many and give scientific information to none.

Handbuch der physiologischen Optik. Von H. VON HELMHOLTZ. Zweite ungarbeitete Auflage. Mit zahlreichen in den Texte eingedruckten Holzschnitten. Siebenten Lieferung. Hamburg und Leipzig: Leopold Voss. Pp. 481 to 560.

This seventh fasciculus continues the discussion of the subject of the duration of the light impression on the retina, including the momentary impressions by moving objects, the effects of colored circles, and the description of various stroboscopic apparatus, including the anorthoscope. Section 23 treats of variations in retinal irritability, and includes a very full discussion of the subject of after-images, both positive and negative. Section 24 gives a most interesting account of the subject of contrast in color, both successive and simultaneous

contrast, including colored shadows, and the contrast in colors upon a large colored field. The whole subject has been very carefully gone over, but little has been added to what was contained in the first edition. The eighth fasciculus is announced to appear shortly.

Reports on the Progress of Medicine.

ORTHOPÆDIC SURGERY.

By HENRY LING TAYLOR, M. D.

The Forcible Straightening of Angular Deformities of the Knee.—A novel and efficient method of correcting old deformities at the knee joint is reported by Dr. Joel E. Goldthwait, of Boston (*Boston Medical and Surgical Journal*, Dec. 1, 1892). The operation is done under ether anesthesia by means of an apparatus devised by Dr. E. H. Bradford, and afterward modified by Dr. Goldthwait, with special reference to the correction of the subluxation. The apparatus is arranged to make pressure forward behind the head of the tibia, the counter-pressure being taken in front upon the femoral condyles. The head of the tibia is pressed forward by the mechanism, and the apparatus is also used as a lever to reduce the flexion. The author reports good results in the six cases in which it has been tried.

His conclusions are that angular deformities of the knee with fibrous ankylosis, resulting from chronic inflammatory conditions, whether tubercular or other, can be corrected by means of such mechanical appliances as are here described. The results, judging from six cases, are better than can be obtained by means of other operations. The leg is not mutilated or shortened, and the joint recovers with more or less power of motion. There is no mortality, and constitutional disturbance is slight. The danger of injuring the structures in the popliteal space is trifling, because of the anatomical arrangement of the parts as shown by dissections.

The author demonstrated the method and gave histories of five additional cases at the May meeting of the Orthopædic Section of the New York Academy of Medicine.

The results had been excellent in all the cases but one, where an abscess had followed. Many of the cases had been condemned to amputation or excision, but gave excellent results, the amount of mobility gained being surprising. The method is applicable only in old cases without tenderness or other evidence of inflammation, and where bony ankylosis is absent.

Fibroplastic White Swelling.—E. Nicaise (*Revue de chirurgie*, October, 1892) cites two cases of fibroplastic white swelling—tubercular arthritis with fibroplastic and fatty hyperplasia of the synovial membrane. He found a large part of the synovial membrane of the knee joint much thickened by the deposit of fatty fibroplastic material. Both patients were tubercular, and both had serous abscesses in the vicinity; in both the joint was much enlarged. Dr. Nicaise regards these cases as presenting a primary hypertrophic lesion, due to mild tubercular irritation of long standing, not as a late stage in the metamorphosis of ordinary fungous arthritis, though the latter process may in healing present fringes or nodules of fatty fibroplastic material on a smaller scale. He also excludes sarcoma. In both cases the fibroplastic change was in the anterior parts of the joint. In one the mass was over an inch thick. In the other the superior synovial pouch was obliterated by a large mass of this tissue. In neither was there suppuration or superfluous fluid in the joint.

Genu Valgum.—In Professor Wölder's clinic (Gratz), according to E. Regnier (*Arch. f. klin. Chirurg.*, xliii, 1892, 2), Macewen's supracondyloid operation is recommended, except in a few cases, where the principal deformity is below the knee, where osteotomy of the tibia and fibula is preferable. The deformity is reduced gradually by elastic traction, beginning a week after the operation. Seventeen successful cases are reported. The average duration of treatment was eighty-eight days.

A Paradoxical Symptom in Genu Valgum.—Dr. E. Estor (*Nouv. Montpellier méd.*, March 25, 1893) says that in the normal state, if the leg is fully flexed upon the thigh, the heel will come to lie a little to the inner side of the middle of the buttock. Now, as genu valgum is an exaggeration of the normal angularity existing between the tibia and the femur, with hypertrophy of the internal condyle, and as all observers admit that the deformity disappears on forced flexion, one might suppose that the heel would be carried still farther inward and rest upon the intergluteal crease; but this is not the case. After showing errors in the explanations of Tillaux, Albert, and Phocas, the author approves of that of Guéniot, who says that the knock-knee is corrected in flexion because the articular surfaces of the tibia are in relation with the posterior surfaces of the femoral condyles, which are normal. In the majority of cases, however, the condylar hypertrophy is general, and the projection of the posterior surface of the internal condyle forces the leg outward in flexion. The author observes that in genu valgum the tibia is generally bent at its upper part, the convexity being inward, which favors the coincidence of the direction of the lower part of the tibia in flexion with that of the femur.

It should also be remembered that the movement of forced flexion is one executed by the surgeon; he takes the leg in his hand and applies the heel to the buttock, which is always possible from the laxity of the lateral ligaments in flexion, even if a voluntary movement of flexion did not place it in this position.

Sacro iliac Disease.—Dr. Ridlon and Mr. Jones give a clear account (*Annals of Surgery*, March, 1893) of this affection, which is very rare and is usually secondary to lumbar Pott's disease. It generally occurs between the ages of seventeen and thirty, and is nearly always tubercular. The diagnosis is obscure, and the disease is rarely recognized before suppuration occurs, though it may run its course without suppuration. Van Hook believes that in the dry form the prognosis is good, in the suppurative form exceptionally bad; it appears to the authors, however, that the symptoms detailed of many of the non-suppurative cases hardly warrant the diagnosis of sacro-iliac tuberculosis, and that the fatal termination in the suppurative cases has more frequently been due to the character of the operative interference than to the nature of the affection. "Any operation which fails to remove all tuberculous material and to close the cavity by primary union without drainage should be recognized as distinctly adding to the risks to the patient's life." A fatal termination is usually due to septicæmia, simultaneous or intercurrent tuberculosis elsewhere, or general miliar tuberculosis.

The first symptom is usually a peculiar attitude, a "listing" of the trunk toward the affected side, and as this progresses the spine assumes a long, sweeping curve with its convexity toward the sound side. Before there is much deformity the patient is easily fatigued, and has experienced difficulty in bending forward and rising up again; ultimately stooping becomes impossible. The gait becomes waddling, and finally the patient is unable to walk. There is usually no thigh flexion, though there may be from psoas contraction, and there may or may not be apparent lengthening or shortening of the limb

of the affected side. The patient in standing rests upon the heel of the affected side, but puts nearly all the weight upon the sound leg. If referred pain is present, it is usually felt in the lower abdomen, but may be complained of along the front of the thigh and along the sciatic distribution. Early swelling is directed inward toward the interior of the pelvis, and may be felt *per rectum*. Sooner or later an external swelling appears, which usually progresses to fluctuation. Such abscesses usually burrow extensively; they may go upward in the multifidus spinæ into the lumbar region, through the anterior ligament along the psoas or iliacus, along the pyriformis into the buttock, or inward into the bowel. Atrophy of the buttock and thigh is uniformly present. Pressing deeply over the joint, or pressing or pulling the pelvic bones, usually produces pain. At times there is a tilting of the bones on each other. All the hip motions may be restricted, but if the thigh is slightly flexed so as to relax the psoas, all movements except those of extension and inversion are normal. A contracted psoas also limits motions of lumbar spine. The diagnosis from Pott's disease and hip disease can be made only by remembering that disease in any joint restricts all its normal movements to some extent. The authors reject ambulatory apparatus, and recommend immobilization with a Thomas double splint with the addition of a broad leather girdle; also recumbency until some time after the active stage of the disease has passed. As the disease usually appears in adult life, and the joint is readily accessible, the authors believe that on the appearance of suppuration operative measures should be considered, and that they are oftener indicated than in disease at any other joint. If an abscess can be detected within the pelvis the bone may be trephined, the abscess cleansed, diseased bone removed, the bone cauterized, and the wound closed. In the absence of fluctuation an incision may be required by œdema or tenderness, and the bone trephined for a casing center. The authors believe that to repeat the operation, if necessary, entails less risk than the insertion of a drainage-tube. After the operation the joint should be immobilized and the patient confined to bed till after the disappearance of all local tenderness.

At a meeting of the London Clinical Society (*Lancet*, March 18, 1893) Mr. Makins reported three cases of suppurative sacro-iliac disease—one in an adult, treated by trephining; two in children, treated by arthrotoomy with erosion. It was urged that the prognosis was better than the text-books usually laid down. The treatment should be the same as in tuberculous affections of other joints. Mr. Hulke considered that the cases were too few to draw general conclusions from as to prognosis. Mr. Gould said the general opinion was that the prognosis was exceedingly grave. He had treated three cases. Of these, the first, that of a woman, aged twenty four, had ended in recovery after scraping out the abscess cavity. In the second, that of a man of sixty, a sinus had persisted after scraping. In the third, that of a woman under thirty, he had removed all the bare bone he could, but had not been able to avert a fatal result. There had been very extensive disease of the sacrum and ilium.

The Modern Treatment of Joint Tuberculosis.—Professor König (*Arch. f. klin. Chirurg.*, vol. xliv, No. 3, p. 592; synopsis in *Revue d'orthopédie*, Jan., 1893) classifies the modern treatment of joint tuberculosis as follows: 1. Radical local operation. 2. Local injections of medicaments. 3. Mechanical treatment. He rejects absolutely early resection, employs continuous traction to correct deformity, and applies an immobilizing apparatus of plaster which is renewed with proper correction every six or eight weeks. He reports cures in full half of the cases by these means. Certain others are cured by iodoformized injections. The remaining cases and those of patients who can not spend the time necessary for cure by these means come to excision.

Of 410 cases of tuberculosis of the hip at the Göttingen clinic, 150 were treated by extension and plaster splints, and 50 patients had in addition injections of iodoform in glycerin; 210 were subjected to excision, with a mortality of 19 per cent.

In the knee, 100 resections in adults from twenty to sixty-six years of age gave the following results: 12 patients died, 64 were cured, 16 recovered with sinuses, 8 had to be subjected to amputation. In an investigation in 1888 the author was able to trace 70 of these patients. Forty-four were well and able to work, six had sinuses, and twenty had died, most of them of tuberculosis.

In Bardeleben's clinic (*Charité Annalen*, vol. xvii; note in *Centralblatt f. Chirurg.*, Jan. 7, 1893) there were from April 1, 1890, to April 1, 1891, 32 resections with 7 deaths, or 21.9 per cent.; of these, 13 were of the hip, with 5 deaths, or 38.5 per cent.; and 8 of the knee. Of the latter, 4 came to amputation eventually.

Lateral Curvature of the Spine.—For the treatment of severe cases Mr. Noble Smith advises (*Annales d'orthopédie*, March, 1893) the use of Chauce's apparatus acting on the principle of antero-posterior support. He lays special stress on the importance of studying and carefully following up each case, and adapting and modifying apparatus according to the necessities of treatment.

Of the Ling, or Swedish, system of movements, the author says: "They have little action in causing the disappearance of permanent curvatures. They develop the muscles and improve the general health of the patients; but these are effects which can be produced by any well-devised system of gymnastics, especially by passive exercises." "Ling's exercises, of little value even in cases of slight osseous deformity, are absolutely contraindicated in the graver cases." His opinion of the plaster jacket is as follows: "The treatment which consists in the employment of plaster jackets, in cases of grave deformity, is certainly the most fallacious that there is. Many of the surgeons who were at first enthusiastic partisans of this treatment, having learned better by experience, have abandoned it, as not fulfilling the hopes which were entertained for it. These appliances must be absolutely rejected: first, on account of their considerable weight; second, on account of their interference with respiration and cleanliness; third, because it can only be said for them that they are very heavy, compress the thorax, and afford very little support for the spine." He has an equally unfavorable opinion of felt jackets. He calls attention to the superiority of annealed steel, which can be bent and will retain its shape, and is thus superior to all other materials, including aluminium and bronze, in the construction of spinal apparatus.

He intimates, in conclusion, that the application of combined surgical and mechanical knowledge in the treatment of these cases can not fail to give better results than when work and responsibility are shared by the surgeon and the instrument-maker.

Voluntary Knee Luxation.—Professor J. Wolff (*Zeitschrift für orthopädische Chirurgie*, vol. ii, No. 1, 1892) describes a unique case of voluntary congenital knee luxation, with anomalies of nearly all the joints of the body, in a girl nine years and a half old. Most of the joints showed abnormal laxity of the capsule and ligaments, permitting of luxations and subluxations in various directions. There was a permanent congenital luxation at each hip and at the left knee; the latter had been reduced by a partial resection of the knee in 1887; the patella was rudimentary; some motion remained. There was a movable, congenital dislocation at the proximal extremity of each radius, and there was a voluntary luxation at the right knee. The patient was able to displace the right tibia forward and upward at will

by muscular contraction, and also to replace it. It could also be displaced and replaced passively. There was no functional disturbance, because the displacement never occurred involuntarily in standing or walking. When the patient was lying quiet the luxation occasionally occurred spontaneously, but it could always be prevented if the patient thought of it. When the luxation was present and the patient recumbent the knee could be superextended to nearly a right angle, and lateral mobility in this position was much increased. When it was not luxated superextension existed only to 170° and there was less lateral mobility. The bones forming the knee joint, including the patella, were in their normal relations. The author believes that there was a congenital laxity of the ligamentous structures of the joints, causing the permanent luxations in these joints, and suggests such laxity as an ætiological factor in congenital luxations or in a certain number of them. He suggests that the shallowness of the acetabulum may be a result rather than a cause of congenital luxation at the hip, and that position and pressure *in utero* must be a more infrequent cause than is stated by some authors. Malpositions at birth, so frequently observed in these cases, may be the result of the ligamentous flaccidity, rather than the cause of the luxations. The author has found only eight cases of voluntary luxation in medical literature. Of these, six were of the hip, four unilateral, two bilateral, one was of the patella, and one of several joints.

Absence of the Patella.—A case of this rare anomaly is reported by Dr. V. Ménard (*Revue d'orthopédie*, March, 1893). It was observed in a boy four years and a half old, the subject of congenital luxation of the right hip. The patella and connected tendons were completely wanting on each side. There was fair but diminished power of extension at the knees through the vasti, and there was very little functional disturbance. The child's walk was only modified by the hip luxation. Cases of complete absence of the patella are rare, though cases where it is so rudimentary that it at first eludes observation are more frequent.

Spontaneous Luxation of the Patella.—Dr. Ménard reports also (*loc. cit.*) the case of a boy of eight, the subject of Pott's disease, with this abnormality of the left patella, which came on without accident, and was first noticed by the parents when the boy was three or four years old. When the patient was recumbent, with the knees extended, there was no noticeable difference between the two knees. The left patella occupied its normal position. At 45° of flexion the left patella slipped outward from the trochlear surface, and at 90° of flexion its internal border looked directly forward. In this position it could not be replaced; as extension took place, the reduction occurred spontaneously. When the knee was flexed it was impossible to prevent displacement. When it was flexed at a right angle contraction of the quadriceps could not initiate extension, which was at first aided by the hands, but was completed by muscular effort. There was no deformity of the femur, tibia, or patella, and the displacement was due to thickening and retraction of the femoral aponeurosis and the external ligament. The patient did not limp.

Lateral Deviations of the Thumb Joints.—Two cases of this rare deformity in a mother and son are reported by Dr. Joachimsthal (*Zeitschrift für orthopädische Chirurgie*, vol. ii, No. 3, 1892). The mother, forty-one years old, had a congenital deviation of the terminal phalanx of the thumb to the ulnar side on each hand. The angle was about 150° on the left side and 160° on the right. Motion was free, and the lateral deformity disappeared on flexion, as in genu valgum. In the flexed position a marked prominence of the capitulum of the proximal phalanx was felt on the radial side. The deformity could be overcome by pressure on the ulnar side of the distal phalanx.

The woman's sister's child had the same deformity; a second child of the same sister had the same deformity on the right side, and on the left hand a supernumerary thumb.

The second case was that of the woman's ten-year-old son (her second child). Her two other children were free from deformity. The patient had a severe congenital right clubfoot. The thumbs presented in an increased degree the deformity shown by the mother. There was no direct interference with their function. This deformity has been called *clinodactylia* (*Klinodactylie*) by Herzog, but the author proposes for lateral deviation of the phalanges the names *digitus* and *pollex valgus* (or *varus*, if to the radial side), and calls attention to the analogy with *genu valgum*.

These cases were not treated, but the author believes the thumbs could be straightened by appropriate splints. These and other congenital anomalies occurring with congenital clubfoot and not explicable by the uterine-pressure theory tend, as the author points out, to discredit it as an adequate explanation of the causation of clubfoot.

Congenital Torticollis.—Murray (*Liverpool Medico-chirurgical Journal*, July, 1892) rejects the traumatic and neurotic theories of the origin of congenital wryneck, and believes the deformity is due, as in congenital talipes equino-varus, to a "permanent though sometimes exaggerated condition of the physiological position" during intra-uterine life. There was a history of cross-birth in six out of his seven cases.

Scoliosis Capitis (Caput Obliquum).—This is a well-defined congenital deformity of the cranial and facial bones, so that in a vertical view the head appears compressed in one diagonal diameter, elongated in the other. Dr. Beely, of Berlin, gives histories of seventeen cases (*Zeitschrift für orthopädische Chirurgie*, vol. ii, No. 1), associated with other congenital pressure (?) deformities, as follows: With torticollis, seven times; four times with retraction of a sterno-mastoid; three times with no observable shortening. With scoliosis, demonstrably congenital in most of the cases, seven times; with congenital pes equino-varus, twice; with genu valgum, twice, etc. It does not appear alone and has often been observed in boys than in girls—14 to 3. There is little tendency to recovery, and treatment is not required. The author calls attention to the value of this deformity as evidence that the accompanying deformities belong to the category of congenital pressure deformities. The author incidentally remarks that myotomy is rarely called for in congenital torticollis, where manual and instrumental stretching are carefully and perseveringly applied.

The Treatment of Torticollis.—In obstinate cases of this deformity Lorenz advises (*Brit. Med. Jour.*, April 8, 1893) division of both heads of the contracted sterno-mastoid through an open incision just above the clavicle. The sheath and any contracted bands of fascia are also divided. The secondary scoliosis is overcorrected by manual force during anesthesia, and the neck is held in this position for from eight to ten days by means of a bandage. The after-treatment consists of appropriate exercises. He reports twelve cases cured and no failures.

The Anatomy of Congenital Equino-varus.—The observation was made by Dr. Hubert L. Burrell (*Annals of Surgery*, March, 1893) on a seven-months child that lived four hours. The right foot was normal. The left had a moderate equino-varus deformity; the anterior part of the foot could be corrected manually, but the sole of the heel tended always to face inward. The axis of the foot was curved with the concavity inward; the plantar fascia was slightly contracted. Any attempt at correction put the tendo Achillis, the flexor longus digitorum, the flexor longus hallucis, and the tibialis posticus on the stretch. The skin over the tendons, as they crossed the inner border of the foot, was tense when the foot was in a cor-

rected position, and dissection showed it more adherent than is normal. The astragalus of the deformed foot was small, its neck short, its axis curved with the concavity inward, its articular surface anteriorly smaller than normal. In the normal foot the articulating surface of the astragalus with the tibia had three facets: in the deformed foot two, one for the tibia and one for the external malleolus; the facet for the articulation with the fibula was covered with connective tissue instead of glistening cartilage. The outer part of the head of the astragalus, as it articulated with the scaphoid, was distinctly diminished in size. The interarticular ligament between the astragalus and the os calcis was rudimentary. The plane of the superior articulating surface of the os calcis was oblique and faced inward and upward in the deformed foot, and the depth of the os calcis was considerably greater on the outer side. The os calcis of the deformed foot was small.

Vertical or Slanting Writing.—The question whether a vertical handwriting or the usual inclined form is the more favorable to the position of the penman is being investigated by German specialists.

George Burckhardt (*Zeitschrift für Orthopädie*, vol. ii, No. 1, 1892) gives the results of exact measurement with instruments of precision. He finds the most favorable position for inclined writing is for the page to be about ten degrees to the right of the middle of the body, and not parallel to the edge of the table, but turned fifteen degrees to the left, as in that position the attitude is best. If the lines of the eyes or of the shoulder are inclined either way five degrees or less the position is called "good"; if the inclination is greater the position is classed as "bad." One hundred and thirty-one children writing an inclined hand gave 35, or 26.2 per cent., with a good attitude, and 96, or 73.8 per cent., with a faulty attitude.

For vertical writing the best position is attained by keeping the page nearly in front of the middle of the chest and parallel to the edge of the table. Sixty measurements gave 49, or 81.6 per cent., with good position, and 11, or 18.4 per cent., with bad position; so that the latter mode of writing is to be preferred on the score of attitude.

Obstetric Paralysis.—The pathology and ætiology of this affection are clearly discussed by Dr. C. F. Carter (*Boston Med. and Surg. Jour.*, May 4, 1893). He tabulates Lovett's and Burr's reported cases and sixteen of his own, making statistics of thirty-two cases. He concludes that the upper-arm type of obstetric paralysis is due to a stretching of the upper trunk of the brachial plexus (formed from the fifth and sixth cervical nerves) during the process of delivery. This is brought about by traction on the head or pressure on the breech when the shoulder is retarded, or by traction on the shoulder when the head is retarded—not by pressure of the forceps, as often assumed. The prognosis, as a rule, is good, though recovery may be delayed for months or years. Permanent disability is rare.

The muscles paralyzed are the deltoid, supraspinatus, infraspinatus, teres minor, biceps, and brachialis anticus, with the supinators. In some of the severe cases some of the extensors of the wrist and fingers may be involved. The affected arm is held by the side in a position of internal rotation, the elbow pointing outward. The fingers are usually semiflexed. The paralysis is rarely noticed before the second or third day. After a few days the reaction of degeneration is well marked in the affected muscles, and, if one were able to test satisfactorily in such young subjects, diminution of sensation would probably be found on the outer aspect of the shoulder and upper arm and on the radial side of the forearm.

The treatment consists in the use of passive movements, massage, and electricity (galvanism two or three times weekly through the brachial plexus and affected muscles).

Miscellany.

Abscess of the Liver.—We are indebted to Dr. Augustus McShane, of New Orleans, the secretary of the Orleans Parish Medical Society, for a report of the proceedings of a meeting of the society, held on April 29th, at which Dr. A. J. Bloch read an account of a case of abscess of the liver. Resection of a rib was performed and a large opening made into the abscess cavity, giving exit to fully a pint of very foul pus. The further progress of the case was related by Dr. Bloch as follows:

"Fearing to irrigate under chloroform, as the cavity communicated with the lung and the water might clog up the latter and produce death from asphyxia, I packed the cavity with iodoform gauze and had the patient removed to bed. The patient rallied well; his pulse, as before the operation, was 155 a minute, his respirations 40. The following day I irrigated with a two-per-cent. solution of carbolic acid and substituted a drainage-tube for the gauze. The change in his condition the next week was phenomenal; his temperature became normal; his pulse was reduced to 110, stronger and fuller; his appetite was inordinate, eating or asking to be fed whenever awake; his respirations from 24 to 28 a minute. He had been taking a tonic of iron and quinine, and when constipated, a little sulphate of magnesia was given. Each day I irrigated the cavity with the carbolized solution, after which I injected peroxide of hydrogen, followed by iodoform and glycerin (3 iv to 3 vj). On April 15th I went to pay my daily visit. I found my patient in a very gratifying state; he complained a little of hiccough, but so confident did I feel in a future recovery that I promised to let him sit up in ten days. He was prepared to be dressed by the nurse in attendance, the patient assisting himself in the preparation. As soon as I introduced the nozzle of the syringe into the wound he began to cough; this was nothing unusual, as I experienced the same difficulty every day. I stopped for a moment, which gave him relief, and began again very gently to remove the pus. This time the cough became violent; my patient became cyanotic; I immediately grasped his pulse; it could not be felt; I tried every means possible to revive him, with no result; he was dead. I was unable to hold an autopsy and can account for his death to shock only, produced by a rupture of liver attachments, with a flow of pus and water into the abdominal cavity, superinduced by the cough."

In the discussion Dr. Sexton said that an abscess of the liver might open in several different directions: It might discharge into the stomach, into the intestines, or through the diaphragm and the right lung, and it had been known to burst into the pericardium. It was not improbable that the injected liquid might have found its way into the pericardium in Dr. Bloch's case, for the heart had stopped before the respiration. One need not be surprised at the fatal result; most of his own patients had died. Those that had recovered had mostly had superficial abscesses of the left lobe; the large abscesses of the right lobe were generally fatal. He had a case now under treatment in which the abscess was in the right lobe and was quite large. He had made an incision about four months before between the fifth and sixth ribs, and evacuated about two quarts of pus. He had practiced irrigation and passed a drainage-tube through the opening. The cavity had shrunk up so much that the tube could no longer be introduced. The man's wife had for some time performed the irrigating. The patient was now strong enough to come to the speaker's office. He had gained fifteen pounds in weight. Dr. Sexton condemned trephining of the ribs as a routine practice in abscess of the liver, for the following reasons: Necrosis of the exposed ends of the ribs was sure to take place, and thus a new disease was added to the old one. Furthermore, pus was apt to be absorbed through the cancellous tissue of the bone. Second, the traumatism incidental to the operation complicated the case; third, the sharp ends of the rib after the operation acted as an irritant to the surrounding soft parts. He had now in his service in the Charity Hospital a man whose rib had been resected for empyema. The empyema was cured, but the man wanted to have the necrosis attended to. Where practicable, a free incision in an intercostal space was to be preferred to resection. Last year he had had a case of superficial abscess of the left lobe that was working its way to the

surface; the diagnosis had been very easy. In order to help the pus to reach the surface he had directed the patient to lie always on his stomach. He had done this for a while, and his condition had been all that could be desired; but he had become tired of lying on his belly all the time, and changed to the dorsal position. The pus had infiltrated the deeper parts of the liver and the man had died.

The president, Dr. De Roaldes, did not think that the injection of warm water into the peritoneal cavity could have caused death from shock. During the Franco Prussian war, while he was a surgeon in the French army, he said, Dr. Robert, now practicing in Pau, had been abandoned at Amiens, after the battle of Sedan, as unable to continue in service on account of sickness. Subsequently his old teacher, Dr. Moutard-Martin, diagnosed a hepatic abscess. The abscess was opened with a free incision, and irrigation practiced. During the irrigations the doctor frequently spat up mouthfuls of injected liquid. Dr. De Roaldes had seen Dr. Robert two years ago; he was then a healthy man, and did not look at all as though he had once been regarded as a hopeless invalid. In those days resection of the ribs had not become popularized. Altogether Dr. De Roaldes had treated about thirteen cases; of these, only two had ended in recovery. One of the successful cases was that of a vegetable dealer of strong build. He resected an inch and a half of rib, which afforded free drainage; but he afterward had to treat the necrosis of the exposed ends of the rib. In the other case the abscess was opened with the galvano-cautery and simply irrigated. In another case, in consultation with Dr. Gaudet, the abscess was also opened with the galvano-cautery and the cavity packed with iodoform gauze. In a case that he saw with Dr. Renshaw, the abscess was opened and irrigation practiced. One day while they were irrigating, some liquid came out that had not gone in; the patient's wife recognized it as some broth that he had swallowed a few minutes before. He also vomited some carbolized water and had a diarrhoea of carbolized water. Later, a solution of some aniline dye was injected, and the man vomited some of the colored liquid and had a colored diarrhoea.

Dr. Mats said that the subject was one of unusual interest to him on account of the rather large number of cases that had come under his observation. When he had stated at the last meeting of the State medical society, in 1892, that he had treated more than twenty-five cases since 1880, some surprise had been caused by the statement. He had not been able on that occasion to state the exact percentage of mortality or of recoveries, because he had not yet tabulated and analyzed his cases, but he intended to do this fully in a future paper, and the results, he thought, would show a positive gain in the percentage of recoveries since the adoption of modern surgical methods. His ideas as to the prognosis of hepatic abscess had been positively changed for the better since his student days. When he was a resident student at the Charity Hospital, thirteen years ago, he had been impressed most unfavorably with the career of these cases, so that he had begun his practice with the conviction that the diagnosis of hepatic abscess was almost as bad as a patient's death warrant. The unfavorable results then had been due, in his opinion, to the extreme conservatism of the times, which had caused the practitioner to avoid an active surgical interference. The patients were treated in the medical wards and repeated aspiration with some modifications was the rule. The result was protracted hectic, increased loss of liver substance, and final death from marasmus. Operation by incision, if performed, was always done late, after all other measures had been exhausted and the patient was reduced to the most unfavorable condition for true surgical interference.

He thought that he had met with all the classical and typical conditions of hepatic abscess and many others that were not typical. He had not met with an accident such as recorded by Dr. Bloch. In an abscess which had not burst into the bronchi he thought irrigation was certainly indicated and free from bad consequences. In the liver it was not as in the pleural cavity, where injection with even sterilized water had been followed by disastrous and even fatal consequences. He could not believe that death had been caused in Dr. Bloch's case by the escape of some of the injected fluid into the peritoneum, because the accidental escape of the hepatic pus of tropical abscesses without fatal results had been recorded; especially had this been noticed by the French, who, in their recent and extensive experience in Annam and

Cochin China, had learned to practice the early evacuation of hepatic abscess by incision, without waiting for adhesions to form.

He himself made it a practice to wash out the abscess cavity thoroughly, and for this purpose always endeavored to gain free access to the interior of the cavity by free incision. He had at present in one of his wards in the Charity Hospital a case of enormous abscess of the right lobe of the liver which illustrated his usual practice. In this case a free incision was made in the right hypochondrium, which allowed a good inspection of the interior of the cavity and revealed an anfractuous surface lined with partially detached and disintegrating sloughs. During irrigation, with a hot dilute solution of peroxide of hydrogen (a hot solution of common salt was used very frequently), the interior was swabbed and scrubbed carefully with a large mop of absorbent cotton or sterilized gauze held in the bite of a long hysterectomy forceps. This served the purpose of a safe blunt curette. It was necessary to do more than simply evacuate the pus; we must scrub away the partially detached masses of sphacelated tissue that line the cavity, for they could never be expelled by simple irrigation through a tube, unless by a long and wasting suppuration. In this particular case there was a long history of protracted hectic and dysentery.

The patient was marasmic to an extreme degree. The speaker had even hesitated as to the propriety of any operation. Still, he had felt it his duty to give the man a chance, and, as he appeared to stand the anæsthetic (ether) better than had been expected, he had treated the abscess in the usual way. The right lobe reached the crest of the ilium, and over three quarts of pus escaped through the abdominal incision. After swabbing of the interior with a cotton mop the cavity was packed thoroughly with iodoform gauze (five-per-cent.) saturated with an emulsion of iodoform and glycerin, five-per-cent. The external dressings consisted of a heavy layer of bichloride gauze covered with absorbent cotton and held in place by a broad roller bandage. The patient rallied perfectly from the operation, much to the operator's surprise, yet the dysentery returned, as frequently occurred in these cases, but was checked finally. Over three weeks had elapsed since the operation, and the abscess was becoming smaller every day; the appetite had returned; there had been no fever; but in the last twenty-four hours a diffuse lymphangitis of the right foot and leg had set in which it was feared would alter the patient's prospects most unfavorably. Dr. Matas had tried the new antiseptic, *alumnal*, in this case. He was not dissatisfied with the iodoform emulsion which he always used in systematically packing the cavity, but he thought that he had here an excellent case in which to test the reputed pus-inhibitory properties alleged for this agent. The *alumnal* was used in glycerin solution (five-per-cent.), with which the cavity was freely irrigated before packing. These irrigations were made daily for a week, and were perfectly well borne by the patient. There was no irritation, and Mr. Lovell, the interne of the service, who conducted the after-treatment, was well satisfied with it; still it is difficult to estimate the comparative merits of a new agent in one case.

What Dr. Matas desired to emphasize most was the *early surgical* treatment of hepatic abscess, and by this he meant free incision, blunt curetting (scrubbing), irrigating, and thorough antiseptic packing. This was the ideal treatment applicable, because it converted an internal abscess into an open wound.

An incidental question was that of resection, or rather the resection, of one or more ribs in order to gain free access to the cavity. This procedure should not be arbitrarily or unconditionally condemned. There were cases in which it was indicated, and others in which it was not. We should be guided by the condition of the abscess and of the patient. He recalled a case that had come under his observation not long before. The patient was a man from Honduras. He had a large dysenteric abscess of the right lobe, which pointed below the ribs. It was simply incised, irrigated, scrubbed, and packed. One year after, the same patient had come with another abscess, but this time it involved the convexity of the liver, and Dr. Matas was compelled to resect three inches of the sixth rib in order to open a free avenue into the cavity. The patient again recovered, and he did not have necrosis of the exposed ends of the rib; indeed, that had not been noticed in any of his cases. In another case, which he had treated with Dr. Veazie, the liver had retracted under the ribs after a simple incision in

the hypochondrium; and in order to pack the cavity thoroughly he resected four inches of the right costal arch and made thereby an osteoplastic flap which allowed a free exposure of the hepatic cavity. Dr. Matas was opposed to trephining the ribs, because it was easy to injure the intercostal vessels and nerves, and because unnecessary traumatism was caused thereby without the compensatory advantage of a sufficient opening. The ribs should be excised subperiosteally with the periosteotome. The soft parts could easily be peeled off from a rib by simply passing a strong strip of sterilized gauze under the rib and moving it backward and forward in the manner of a chain saw. The denuded rib might be excised with a costotome, a bone-cutting forceps, or a short saw, to any desired length.

The American Medical Association.—In the *Journal of the American Medical Association* for June 24th Dr. Culbertson announces the termination of his editorial connection with the *Journal*, and makes certain statements in regard to the condition of the association.

"With an election of four new trustees," he says, "there was necessarily a practical reorganization of the board, under which the editor was not a candidate for re-election. His official relations with the *Journal* will cease with this issue.

"As the editor of the official organ of the American Medical Association for two years, the writer has obtained an insight into the workings of that organization which leads him to make the following statements of fact and opinion:

"The American Medical Association reached its highest membership in 1888 at Cincinnati. That city is located near the center of population of the United States, and the meeting was boomed through the local journal. Since that date there has been an annual decline of members and of revenue from their dues. The delinquents have been quite regularly every year a little more than forty per cent. of the members to whom the *Journal* is regularly mailed, which indicates faulty collections. While this may be the fault of no one in particular, it is no doubt mainly caused by the distant separation of the treasurer from the *Journal* office.

"In December, 1891, when the publication of the list of members was made, we were gratified at an apparent increase in members, which was, however, more than offset by the immediate receipt from the treasurer of a list of almost five hundred names to be dropped as delinquents. The past year has witnessed an increase followed by a larger decrease.

"The scientific work of the association has kept quite fully abreast of the age; the interest in section work has been very gratifying, and every year has brought an increasing number of scientific papers.

"This apparently anomalous condition leads to an inquiry as to the cause, which we find in the faulty constitutional organization of the association. It is at present a delegate body, and as such must annually draw its strength from the immediate locality of a meeting. Such a process insures growth up to a certain point, when the decrease begins to equal the increase and a liability to retrogression for a term of years as we are now witnessing. The registration at Milwaukee was one hundred and ninety-eight less than a year ago in Detroit, and surely this was not from lack of interest or appreciation on the part of physicians near to Milwaukee.

"Furthermore, the delegate system prevents the registration of all regular physicians at a place of meeting; for instance, in Detroit there were registered three hundred and eighty-five new members. These were delegates representing three thousand eight hundred and fifty physicians, every one of whom should have had an opportunity and a right to register as an active member. The same condition and effect will be shown at the Milwaukee meeting.

"Next year the meeting will be in San Francisco, and the delegates from that State said the Pacific coast had three thousand five hundred physicians. Suppose it has; only three hundred and fifty can become members of the association if every Pacific coast delegation is absolutely full, and constituted of new members. Says an old member: They can all become members by application. True, but they don't, and won't come in that way. It may seem to some like a very little thing to be deprived of a right to vote; but on that little thing hinges the right of equality and sovereign citizenship. To be deprived of that right is antagonistic and repugnant to American physicians. It has

been tried and don't work or go. Hence the absolute necessity for an abandonment of the delegate system of membership. Another cogent reason is the domination of votes in any meeting from the immediate locality. Milwaukee was entitled to about twenty delegates, but even that small number was greater than the entire representation from all the New England and Pacific coast States.

"The apparently feasible, practical solution of this question will be found in a modeling of the association constitution on the plan of the General Government of the United States, whereby the American Medical Association will become a federation of State medical societies, the members of the State societies, by reason of such membership, being members of the American Medical Association. The official relations of the State societies should be maintained by an appointment or election of one or two State society members to represent their States in the business committee of the American Medical Association. These official State society representations would give national character to the organization. The executive committees of the several sections as now constituted would give in the business committee a fair representation of the science and art of our profession. The business committee so constituted, representing every State in the nation and every special scientific department in medicine, becoming the legislative body of the American Medical Association and performing the functions of the nominating committee. This legislative branch of the American Medical Association should formulate and submit all measures that may seem desirable for reference and action to the several State societies, a majority of such societies governing the result of action upon such subjects, only such matters being sent to the State societies as pertain to the general interest of the medical profession of the nation. Providing, also, that in this federation of State societies there shall be represented but one such organization from any State.

"To the State societies in this national federation should be sent all amendments proposed for the constitution of the American Medical Association, and also amendments and revision of the code of ethics. The latter, when agreed upon, should be recommended to the State societies for adoption, but not made mandatory upon such societies.

"With a reorganization upon such a basis as the one outlined, there is no limit to the possible strength and growth of the American Medical Association, while its influence for good in all that pertains to the welfare of physicians and to the people would be immeasurable.

"Unless some such action is taken by this grand old representative body, there is imminent danger of disintegration and the formation of another body of national character, that will attempt to do the work that should be accomplished by the American Medical Association. This is a danger that is now menacing the American Medical Association. To be forewarned calls for a forearming."

The Innovations in the Army Medical Service, mentioned in general terms in our last issue, are thus set forth in the *Washington Evening Star*:

"The course of special instruction will be given in this city and will constitute what will be known as the Army Medical School. It will be conducted in the Army Medical Museum and will be of four months' duration. Four of the senior medical officers stationed in this city will, in addition to their other duties, conduct this course.

"One of the officers will act as president of the faculty and will lecture upon the duties of a medical officer in time of peace and war, the methods of conducting official correspondence, making reports to the department, the discharge of soldiers on certificates of disability, the examination of recruits, the rights and privileges of medical officers, their relations to other officers, and the customs of the service. His associates on the faculty will deal respectively with the subjects of military surgery, of military hygiene, and of clinical and sanitary microscopy. The course will be a practical one and include laboratory work, with the idea of making the young medical officer familiar with the most accurate methods of the sanitary examination of the air, water, and food; the recognition of known disease germs; the microscopic examination of morbid growths, etc.

"The other project of General Sternberg is to give the officers of the medical corps the advantages accruing from metropolitan life. He proposes to change the system of assigning medical officers for duty as

attending surgeons in the large cities. It has been the custom heretofore to detail for this purpose the older medical officers of the army. The duty usually lasts three or four years. In some cases it has lasted ten or a dozen years. The duty of the officer so detailed is to attend army officers and their families in and about the city of his location. Dr. Sternberg will hereafter detail medical officers having the rank of captain to duty as attending surgeons. The tour of duty will last only one year. By this system the medical officer selected will be enabled to become familiar with the practice of the leading physicians and surgeons in this country and to attend medical lectures and meetings of medical societies. The experience and observation will fit them the better for their second examination, which is required by law before they can be promoted to majorities.

"The details will be made in Boston, New York, Philadelphia, Baltimore, Chicago, St. Louis, and San Francisco. The senior medical officers who have heretofore been stationed in several of these cities as attending surgeons will be required to perform the more responsible duties of post surgeons at the larger military posts, where, as a rule, one or more younger officers will also be stationed as assistants. This policy will not only give the younger men of the medical corps better opportunities for professional advancement, but it will give them the benefit of the experience of their seniors and of the necessary instructions and discipline which so often in the past they failed to receive. This failure is due to the fact that they were stationed usually at remote frontier posts and were thrown upon their own responsibilities before they had the opportunity to make themselves familiar with the special duties of the medical officer of the army and the customs of the service.

"Both of these plans have received the approval of Secretary Lamont and steps will be taken to put them into execution as soon as practicable.

"A general order providing for the establishment of the army medical school referred to above was issued by Adjutant-General Williams to-day as follows:

"By direction of the Secretary of War, upon the recommendation of the surgeon general of the army, an army medical school will be established in the city of Washington for the purpose of instructing approved candidates for admission to the medical corps of the army in their duties as medical officers.

"The course of instruction will be for four months and will be given annually at the Army Medical Museum in Washington city, commencing on November 1st.

"Four professors will be selected from among the senior medical officers of the army stationed in or near the city of Washington, and as many associate professors as may be required to give practical laboratory instruction in the methods of sanitary analyses, microscopical technique, clinical microscopy, bacteriology, urine analysis, etc.

"The faculty of the army medical school will consist of:

"1. A president of the faculty, who shall be responsible for the discipline of the school, and who will deliver a course of lectures upon the duties of medical officers in war and peace (including property responsibility, examination of recruits, certificates of disability, reports, rights and privileges, customs of service, etc.).

"2. A professor of military surgery (including the care and transportation of wounded).

"3. A professor of military hygiene (including practical instruction in the examination of air, water, food, and clothing from a sanitary point of view).

"4. A professor of clinical and sanitary microscopy (including bacteriology and urology)."

Nephrotomy for Suppression of Urine.—In his Cavendish Lecture on Some Changes in Surgical Opinion regarding the Diseases of the Urinary Organs, published in the *Lancet* for June 17th, Mr. Henry Morris, of the Middlesex Hospital, says:

"The advances in renal surgery include nephrotomy for certain cases of suppression of urine, and some success has followed the treatment. The cases of anuria which the surgeon is likely to be called upon to treat may be grouped under two heads: (1) Mechanical anuria, and (2) reflex anuria.

"1. Mechanical anuria occurs after nephrectomy or after destruction by disease of one kidney; by the impaction in the ureter of the remaining kidney of a calculus, bloodclot, or mass of mucus; by a growth in the bladder blocking the urethral orifice; from kinking of the ureter of a movable kidney; or by the pressure on the ureter of some tumor, or by the cicatrization following pelvic abscess or pelvic cellulitis. 2. Reflex anuria, as one of the complications of urethral or urinary fever, has often been attributed to mechanical irritation of the urethra in front of the prostate. Opinions are at variance as to this view; but since the introduction of renal surgery it has been proved that a mechanical irritation in one kidney is a cause of total suppression in both. Thus, after a calculus has been extracted from the right kidney and a fistula has followed, complete suppression of urine due to a calculus in the left kidney has been relieved by extracting the left renal calculus, as shown by the escape of urine through the left side wound and through the right-sided fistula. James Israel has recorded the case of a man, aged forty nine, who for years had suffered from gout and right renal colic, and who at length was seized with left renal colic attended with total suppression of urine and caused by two stones impacted, the one in the renal pelvis and orifice of the ureter, and the other in the ureter a little lower down. As soon as these calculi were removed through a left lumbar incision both kidneys at once resumed their function, as was proved by the qualitative analyses of the urine passed through the bladder and through the left lumbar wound. To save life in such cases of anuria it is necessary to perform nephrectomy on the remaining or last obstructed kidney, and it is to be hoped that surgical opinion, aided by those distinguished physicians who from the first have recognized the beneficial effects of surgery in certain classes of renal affections, will soon cause the operation to be generally acknowledged by the profession as the proper treatment. This view is far from being at present generally accepted. In July last year I was called to see a gentleman, aged forty-seven, who had passed two or three calculi nine years, and again a similar number four years previously. He had ever since had frequent pain in the right renal region. After two days of all but complete anuria he was seen by a physician, who, in reply to the question of surgical interference, said that no surgeon in his senses would dream of operating. I saw the patient late at night on the third day of anuria and recommended pilocarpine, jalap powders, and vapor baths, and further advised that if no effective secretion followed thereupon nephrectomy should be performed. I heard nothing more until the seventh day of suppression, when I was again summoned at the instigation of Dr. Dickinson, who had that same afternoon seen the patient for the first time and had advised an operation, believing the anuria to be caused by calculous obstruction. But it was too late, for before I could reach the house the patient, after making a futile effort to pass water, became suddenly collapsed and died. In 1889 I was called, at the suggestion of Sir George (then Dr.) Johnson, to operate on a lady with a similar history. I performed nephrectomy upon the kidney opposite to the one which had previously been the seat of trouble; but it was too late. The anuria had persisted several days. The patient was aged and very obese, and she died about fifteen hours after the operation, but not before some ounces of urine had escaped into the dressings. In a third case a more satisfactory result followed. On January 5, 1889, I removed the left kidney for extreme hydronephrosis. In December last the right kidney, which was movable, showed marked signs of intermittent hydronephrosis with impaired secretion. Ably seconded by Dr. Knight, the lady's medical attendant, I was permitted to perform nephrectomy and stitch the cut edges of the kidney to the lumbar wound. The patient is now living and doing well, passing some of her urine through the urethra and some through the loin. There is no longer any fear of the further destruction of the kidney or of anuria from obstructed ureter. Surgical literature supplies us with evidence in favor of nephrectomy in such cases. Bardeenheuer, Clement Lucas, F. Lange, and Willy Meyer have each recorded a successful case. In each the operation on the second kidney was clearly indicated not only on account of anuria, but by the pain and other symptoms which pointed to obstruction in the ureter of that kidney. The operation in all four cases would have been indicated if no previous operation had been performed on the opposite kidney, but it became absolutely necessary in order to save life in two

of them by the fact that it was the patient's only kidney which was implicated.

"In a small proportion of cases after nephrectomy or nephrectomy suppression of urine follows—indeed, is caused by the operation—even though no mechanical obstruction whatever is present on the other side. These are typical instances of reflex anuria due to the disturbance of the nerve plexus of the organ operated upon. I have had one case of this kind which occurred in a woman thirty-five years of age upon whom I performed nephrectomy for calculous pyonephrosis. I have not as yet attempted operative treatment for such a case nor do I know of its having been used; but it has been proposed by Meyer under certain specified conditions to treat cases of anuria coming on after nephrectomy by 'an artificial direct depletion' of the remaining kidney with the view of reducing the hyperæmia which follows the ligation of the renal blood-vessels of the kidney removed. I do not think we must be sanguine of the results of such depletion, though the proposal seems to be worthy of trial."

To Contributors and Correspondents.—*The attention of all who purpose favoring us with communications is respectfully called to the following:*

Authors of articles intended for publication under the head of "original contributions" are respectfully informed that, in accepting such articles, we always do so with the understanding that the following conditions are to be observed: (1) when a manuscript is sent to this journal, a similar manuscript or any abstract thereof must not be or have been sent to any other periodical, unless we are specially notified of the fact at the time the article is sent to us; (2) accepted articles are subject to the customary rules of editorial revision, and will be published as promptly as our other engagements will admit of—we can not engage to publish an article in any specified issue; (3) any conditions which an author wishes complied with must be distinctly stated in a communication accompanying the manuscript, and no new conditions can be considered after the manuscript has been put into the type-setters' hands. We are often constrained to decline articles which, although they may be creditable to their authors, are not suitable for publication in this journal, either because they are too long, or are loaded with tabular matter or prolix histories of cases, or deal with subjects of little interest to the medical profession at large. We can not enter into any correspondence concerning our reasons for declining an article.

All letters, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication. No attention will be paid to anonymous communications. Hereafter, correspondents asking for information that we are capable of giving, and that can properly be given in this journal, will be answered by number, a private communication being previously sent to each correspondent informing him under what number the answer to his note is to be looked for. All communications not intended for publication under the author's name are treated as strictly confidential. We can not give advice to laymen as to particular cases or recommend individual practitioners.

Secretaries of medical societies will confer a favor by keeping us informed of the dates of their societies' regular meetings. Brief notifications of matters that are expected to come up at particular meetings will be inserted when they are received in time.

Newspapers and other publications containing matter which the person sending them desires to bring to our notice should be marked. Members of the profession who send us information of matters of interest to our readers will be considered as doing them and us a favor, and, if the space at our command admits of it, we shall take pleasure in inserting the substance of such communications.

All communications intended for the editor should be addressed to him in care of the publishers.

All communications relating to the business of the journal should be addressed to the publishers.

Contributors who wish to order REPRINTS of their articles should do so on a blank prepared for that purpose, which will be sent to them by the publishers on receipt of a request to that effect. The order should be sent to the publishers, and not to the editor.

Original Communications.

THE TREATMENT OF
CERTAIN FORMS OF FRACTURE.*

By CHARLES PHELPS, M. A., M. D.,
SURGEON TO BELLEVUE AND ST. VINCENT'S HOSPITALS,
AND CONSULTING SURGEON TO GOUVERNEUR HOSPITAL.

THE treatment of osseous fracture from rude beginnings has been eminently progressive and has gradually attained a perfection of methods and results remarkable even in the growth of modern surgery. In the management of many fractures it would seem that the possibilities of surgical art had been well-nigh exhausted, and this result has been so largely due to the contributive work of a great number of individuals, widely scattered in time and place and of varied degrees of professional prominence, that an unusual number of persons have come to rightfully regard themselves as identified with this particular phase of surgical progress.

This fact has rendered the subject one of exceptional universality of interest, and, together with its great practical importance to every general practitioner, has been sufficient to give it standing in the deliberations of any medical association not exclusively devoted to the advancement of special subjects. It is an application of the surgical art which, in the exigencies of our profession, even the physician most averse to surgical practice is occasionally compelled to make, and in which the results, when unfortunate, are patent, and become the subject of always severe, sometimes judicious, and occasionally judicial, comment.

It is therefore pardonable, where professional pride and personal responsibility are both so deeply concerned, to traverse well-worn paths, for something always remains to the gleaner. It would be both useless and fatiguing to sketch, even in the most desultory manner, the treatment of fractures, either in general or in classes. Recent authors, Stephen Smith and others, have given it entirely adequate attention. There are, however, certain details and general considerations which, if scarcely demanding extended individual comment, may yet be naturally aggregated as a personal contribution to the subject. In this view some facts and observations here collated are worthy of notice either because of their importance or of their failure of general recognition. They touch the matter at somewhat distant points, but are related by laws of general acceptance and application.

The simplest form of fracture is that of a long bone at some distance from a joint. Its treatment in accordance with the careful methods in vogue during recent years usually affords almost perfect results. Angular deformity under ordinary circumstances, and when the accepted appliances for coaptation, extension, and counter extension are employed, is hardly to be feared; and since the advent of the aseptic era, when the resection and wiring of obdurate fragments became practicable, any considerable distur-

tion is scarcely to be tolerated. Such, in this country at least, where mechanical skill is a common gift of Nature, has long been the happy outlook for those who are still unfortunate enough to suffer this simplest of simple fractures. Up to a much later period abroad, however, eccentric results were still sufficiently common. I well remember, when thirty years ago I first saw foreign museums of pathology, I marveled much at their richness in strange osseous deformities and distortions, but the wonder lessened when I subsequently saw and noted in the service of Velpeau the indifference, carelessness, and neglect in treatment, and the distorted limbs which seemed to quite content even the master in surgery. I doubt not bones in France have since come to unite in more æsthetic form, but I question whether even now results in this particular are comparable with what we are accustomed to see at home.

There is another point of view from which the result of treatment has been less uniformly fortunate, and from which failure is quite too frequent. I refer to the occurrence of non-union and of ligamentous union of the fragments. I shall not attempt to present a statistical account of what may be termed this accident of treatment. I have encountered a considerable number of such cases during the past few years, though it has chanced that none of them were originally in my care. They have involved the humerus, radius, ulna, femur, fibula, and tibia, and the last mentioned has been most frequently in fault. The ætiology which is directly connected with treatment is well known, and the constitutional causes I have found to be more generally operative in the larger bones. Thus in six instances involving the femur two were of syphilitic origin, one was from malnutrition, and the fourth apparently resulted from too frequent disturbance of the fragments at an early period, and to a subsequent cachectic general condition. In a very interesting case, however, in the practice of Dr. S. G. Cook, of New York, it was one of the metacarpal bones which suffered from constitutional cause. Union failed for ten weeks. The patient, who admitted former syphilitic infection, but presented no symptoms, was then subjected to specific treatment, and union began in two weeks' time and was rapidly perfected. It is evident that when the cause is wholly or in part of constitutional origin a corresponding general treatment is of primary importance, but local fixation and the correction of local errors should follow hard upon it. If the fault be essentially local the primary treatment must of course be local, but must often be supplemented by assiduous attention to the improvement of the general health.

I believe it can not be insisted upon too strenuously that possibility of imperfect union always exists. In a large proportion of such cases as have come under my observation the danger could have been averted by sufficiently early recognition and adequately careful treatment. There are instances like that in Dr. Cook's experience in which the clew is lost by absence of specific symptoms, and others in which constitutional depravity is irremediable. There are also instances of local default in which prevision is of

* Read before the Fifth District Branch of the New York State Medical Association, May 23, 1893.

no avail. Compound fractures sometimes, and intracapsular fractures of the cervix femoris always, fail of union. I speak advisedly of the latter lesion and am mindful of the earnest controversy which it incited some years ago, and which was so vigorously maintained by Dr. James R. Wood and Dr. Willard Parker. No one maintained that union seemed even possible *a priori*, but Dr. Parker presented a single specimen in which he believed it had actually taken place. Dr. John G. Johnson, of Brooklyn, demonstrated its fallacious character in a discussion of the whole subject, and no similar contention has since been made. The same anatomical conditions obtain in intracapsular fractures of the cervix humeri and the same result must follow. If full allowance be made for these exceptional instances it still remains that the major part of cases of non-union depend upon remediable causes and defects of treatment. I think it is further true that the error is usually local. If firm, accurate, undeviating, and persistent coaptation be made, osseous union will seldom fail in uncomplicated simple fractures. The present means at our disposal for securing and maintaining coaptation are so varied and so perfect and so readily permit relief from unduly prolonged and exhausting confinement, that the surgeon can rarely escape full responsibility for perfect restoration of the parts. If in fractures of the shaft of the humerus the elbows were always properly supported, if in fractures of the shaft of the femur the fragments were always properly reduced, if in all fractures after the application of proper retentive apparatus it were left without unnecessary disturbance, the opportunities for study in the field of ununited fractures would be seriously curtailed. I dissent strongly from the opinion that it is ever safe to intrust any fracture which is within reach of retentive apparatus to the sole protection afforded by surrounding parts. It is not very long since I saw a case in which an unsuspected fracture of the upper fourth of the fibula had remained ununited for some months, and had led to a subacute arthritis of the knee. It united readily in the usual time after the application of a silicate-of-soda bandage. No fracture could be better supported by thick muscular environment and no result could more distinctly illustrate the efficacy and necessity of surgical aid.

I had not intended to discuss the causes of ununited and improperly unioned fracture, or measures for its avoidance, but rather to consider one or two of the operative methods for its repair. It is always well to regard any case of this nature as simply one of delayed union till after the lapse of a considerable time and the thorough test of absolute immobility, with systematic hygienic and nutritive regimen. Where union is entirely wanting, attrition of the fragments may also be of service.

If operation is demanded, the choice lies between numerous procedures, two of which I have found to be efficient and deem to be simpler and safer than the others. These are (1) drilling, and (2) wiring and resection of the ends of the fragments, and of these the former seems to me, in suitable cases, the one to be preferred. It is certainly the easier of performance, can be indefinitely repeated, and in case of ultimate failure will not prejudice the resort to

more serious operative measures. The femur, of all bones, is perhaps least suited to its employment. In case by any chance purulent inflammation follows, it is liable to be diffused along the muscular planes and to involve loss of limb or even life itself. I have met with one such accident after drilling the femoral fragments, and though the patient escaped dire disaster and eventually obtained proper union without further operative interference, I fully realized the danger to which he had been subjected. I saw in my service as *interne*, before aseptic surgery was practiced, a case in which death did result from diffuse suppurative inflammation of the deeper structures of the thigh after one of the other operations for the establishment of osseous union. The control of deep femoral suppuration is sufficiently difficult under favorable circumstances, but when the constitutional condition of the patient is impaired by long confinement, and perhaps by specific poison besides, and when it is induced by subcutaneous lesion, the difficulty may well become insuperable. I therefore favor an open operation in the thigh which permits early and thorough antisepsis and drainage should they be demanded. Again, in very many, and probably in the majority, of cases there is an overlapping of the femoral fragments, which not only increases the difficulty of firm union, but causes deformity and weakness of the limb. An operation is requisite in which more perfect coaptation and a higher grade of ossific inflammation is obtainable, and in which, at the same time, the strength of the limb can be increased by the relief of deformity. I depend upon the wiring process to fulfill these indications. The seat of fracture is, of necessity, freely exposed, and every opportunity afforded for asepsis and drainage. Coaptation can be accurately effected and reduction of the fragments, or resection, if required, be made with proper care.

I am unprepared to demonstrate statistically its comparative safety or efficiency. Since the aseptic era, with which such comparison must begin, the whole number of recorded cases which have failed of osseous union and have been subjected to operation of any kind can not be large, and I am sure have not been tabulated. I have done this operation in two cases; in one, after resection of two inches and a half of bone, union became firm in thirty-three days and without the formation of pus; in the other, after a resection of one inch, union became firm in forty-five days after prolonged suppuration. In both the fracture had occurred in the middle third, six months previously in the first, and four months in the second. In the first case the subject was a girl of sixteen, suffering from the effects of syphilitic infection and dissipation; the second case was that of a man of twenty-nine, whose history was not clear. The method of operation presented nothing of special interest, and none of the delays and difficulties suggested by Treves were encountered. The question of safety is the general one of a simple wound originally uncontaminated and should hardly occasion anxiety. The certainty of cure, comparative and absolute, must be a matter of estimate in the absence of any large number of cases in modern practice. If the patient's general condition warrants surgical interference of any kind, and always pre-

supposing due skill and care on the part of the surgeon, success as well as safety should be reasonably assured. No other method has been devised in which the fragments can be so accurately secured, and under conditions so favorable to osseous production. If it results in failure, there is no reason to believe that the osteogenic process can be compelled by any other form of direct stimulation.

The consideration of ununited fractures of the humerus follows the same lines and leads to the same conclusions. The anatomical situation is similar and suggests the same views of treatment and of probable results. If there is much angular deformity or overriding of the fragments, or if a false joint has been formed, resection and wiring are likely to be indispensable. If there is simple non-union from want of support to the elbow or from too frequent manipulation during the progress of the case, drilling may possibly be successful, but is still injudicious for the same reason that obtains in case of the femur. In the present very general survey of the subject of mal-unions, it suffices to indicate the points of relation in this regard between the two bones.

In defective union of the smaller long bones of the extremities, notably the radius, ulna, and tibia, the question of treatment presents itself under somewhat different conditions. The fracture is likely to have occurred in a much more accessible position, usually subcutaneously, and even when nearer the head of the bone it has less formidable muscular surroundings. There is consequently diminished danger from the diffusion of pus from an accidental suppuration. The radius and ulna, if not the tibia, are much smaller bones than the femur or humerus, and their osteogenic property is proportionately easier to excite. It is also practicable to maintain absolute immobility without necessitating an irksome confinement of the patient, which is always detrimental to the general health, and indirectly prejudicial to the process of repair. It might therefore be expected that the simpler method of drilling would suffice in case of these bones, and in my experience the result has justified the expectation. I have several times resorted to it for one or both bones of the forearm, and always with success. I have used it in a much larger number of cases for the tibia, and, with the exception of those in which the patient has abandoned treatment, they have all been eventually cured. The exact number I am unable to state, but I think from fifteen to twenty would be a conservative estimate. The fractures of the forearm have all been simple; those of the tibia, in three or four instances, were originally compound. In the latter a loss of substance, suppuration in the wound, or caries and necrosis of the fragments sufficiently account for lack of proper union. In all the radial and ulnar cases I have thought failure to result from original fault of apparatus or its too frequent disturbance in the course of treatment which has prevented absolute immobility, and I have no doubt the same error has been contributive in many of the tibial cases. I have had no reason to suppose that constitutional causes were operative in any of them or that the interposition of the softer tissues had played a part. The essential and determining cause of tibial default I believe to be found in deficient posterior

support. I have certainly very generally observed it to be accompanied by a dropping backward of the lower fragment, which, as I infer, stands in relation of cause rather than of result, from the fact that when its prevention has been the subject of special care union has always been firm. It is not sufficient to apply a plaster or silicate-of-soda apparatus, or to rely solely upon lateral coaptation. In either case, with or without the immovable appliance, a posterior supporting splint of some sort is requisite to safety.

If operation has been finally determined, and drilling selected as the means, nothing can be easier than its execution. It is well to use an anæsthetic, especially in primary operations, but it may be dispensed with on occasion. In private practice, where it is usually available, nitrous oxide is the preferable agent. I have not observed Brainard's advice to use the drill sparingly, but am accustomed to perforate each fragment in every direction, upward and downward, without its withdrawal, and to insert it again, or even a third time if necessary, to reach every part of the bone within an inch or more of the line of fracture. I have not hesitated, with due caution, to wound the soft parts contiguous to the bone. If there is considerable hæmorrhage, it is none the worse for the prospect of cure. The bone is often soft, but in cases of long standing it is more probably eburnated and its medullary cavity empty. It is scarcely necessary to say that every aseptic precaution should be employed with the same thoroughness as in a capital operation. The limb should be dressed aseptically, and, after superficial inflammation has subsided, should be put in plaster for four weeks. At the end of that period, if union is not satisfactorily firm, the drilling should be repeated and the limb again incased in plaster. I know no limit to repetition of operation but success. When union has become reasonably firm, it may be intrusted to plaster for a longer period and the use of the limb permitted. The general health of the patient should receive the same attention as should be accorded in the treatment of recent fracture. If I have been more fortunate in my results than have other surgeons who have less confidence in this method, I attribute it entirely to my greater perseverance, or possibly in part and in some lesser degree to my habit of earlier interference. I know it has been thought wise to defer operation till after the lapse of many months. I am disposed to resort to the drill earlier—in two months even. I can not forget that the greater part of surgery is done in the service of the poor. It is their bones that are oftenest broken and that oftenest fail of solid union. If, then, time, which has to them an extraordinary value, can be saved by operation devoid of danger and fruitful of result, I am quite sure it should not be withheld in view of an otherwise possible recovery in the indefinite future. It is a luxury of dalliance beyond their means. If osseous union is delayed beyond two months it becomes improbable, and with the lapse of time the bone suffers changes which render the operative cure more difficult and more tedious. For a double reason, therefore, I advocate comparatively early interference.

I propose to very briefly abstract the history of three illustrative cases:

CASE I.—A young lady, thrown from her horse, fractured the right radius at the junction of the middle and lower thirds. At the end of two months, when I saw her first, union was still soft. She attributed the defective result, with apparent reason, to frequent removal of the dressings for purpose of examination. I drilled the fragments, and repeated the operation twice at intervals of thirty days before union was satisfactorily firm. The bone was in some way refractured at the same point shortly afterward, and I again used the drill for the fourth time, and without delay. The result was perfect at the end of the usual period, and now, after five years, is without reproach. No anæsthetic was employed.

CASE II.—A young man of twenty-five years was entangled in a rapidly-running rope, and his right leg nearly severed in the lower third. Both bones were comminuted, and the limb held only by the integument and fascia of its posterior aspect. A fragment of the tibia was removed at the first dressing, and others after the necrotic process. The accident occurred on March 19, 1889, and the patient was originally in care of Dr. F. S. Dennis. The wound was not entirely healed till August. Union on the 2d of November was still fibrous, and resort was had to drilling, which was repeated on December 1st and February following, with the application of the plaster apparatus. Union became progressively firmer, and three weeks after the last operation he was allowed to walk with a brace fastened to the shoe. I have seen him within the present month, and his leg is absolutely solid, with an inch shortening and some limitation in extension of the ankle.

CASE III.—A locomotive engineer received injuries in a collision which necessitated amputation of the left leg below the knee, and occasioned a compound fracture of the right leg at the junction of the middle and lower thirds, resulting in fibrous union. He stated that his fractured leg was treated with various forms of apparatus, and that he was allowed to sit up at the end of six months, and three months later to walk with a crutch. The wound at the point of fracture was unimportant and readily healed. The tibia was drilled after fourteen months, at the time he came under my care, and plaster applied. Union became somewhat firmer, and the bone was again drilled at the end of thirty-eight days. In six weeks union was so firm that, after the reapplication of plaster and another drilling, he was allowed to go home into the country and to bear weight upon the leg in walking. The plaster soon broke away at the ankle, and he continued to walk upon the leg without any considerable support. Two months later union was found to be much weakened, and he was again drilled and put in plaster. In another two months union had again become firmer, and he was drilled for the fifth time and sent home in plaster, to return at the end of the summer, three months afterward. I have not seen him since, and have been unable to obtain any information as to his condition.

The second case I regard as the most extraordinary instance I have ever seen of recovery without mutilation from a compound fracture, and the subsequent establishment of osseous union as scarcely less remarkable.

These instances of fracture in which osseous union originally failed for different reasons all teach the necessity of patience on the part of both surgeon and patient. The first and second were ultimately successful because the patients realized the gravity of their condition, and were possessed of sufficient intelligence and resolution to be guided by advice and to persevere to the end of treatment. In the third, a man of equal intelligence ignominiously deserted

when the prospect of cure was entirely hopeful, and left the surgeon not only helpless, but ignorant even whether or not his object had been accomplished. It is this infirmity of purpose which makes not only such cases, but primary fractures as well, often discouraging and always of uncertain issue. Any patient in hospital, or in private practice for that matter, is at any time quite likely to demand his discharge, in order to put himself in the care of an incompetent and irresponsible medical person, and to afford, perhaps, still another example of badly united fracture. The reference to causation in this accident would be most incomplete if attention were not emphatically directed to the patient's own frequent negligence, disobedience, and abrupt severance of professional relations.

Fractures through the extremities of the shaft of long bones constitute a clinical class by themselves. The danger here is less a question of angular deformity or of imperfect union than of fibrous ankylosis. It is true that I have quoted a case of non-union of the fibula near the knee joint, and that the adduction of the lower fragment in fracture of the surgical neck of the humerus is only too constant and too mischievous to escape attention; but the ever-present menace—the one never to be avoided without early recognition and unremitting care—is the limitation of articular movement. The propinquity of the joint is a source of trouble and danger which I may assume to need no explication. The necessity of judiciously early, patient, and prolonged passive motion is too thoroughly taught and understood to require even cursory mention. The use of massage, however, as practiced by the skilled masseur or masseuse, is an adjuvant in treatment of comparatively recent introduction and is worthy of at least passing consideration. It is not new to the profession, but as a definite means of accomplishing a specific object in surgical practice it is even yet imperfectly appreciated. In connection with the passive movements exercised by the surgeon, well-directed massaging and manipulation of the parts may be made of the greatest importance. It renders passive movements less painful, curtails the period of secondary treatment, and gives increased assurance of ultimate freedom of motion; but to obtain its full advantage it should be intrusted only to those who possess the requisite technical skill.

There is a special fracture in the vicinage of a joint which I propose to consider with some particularity, because it is in general so badly treated. This occurs at the lower end of the radius. In its more common form, known by the name of Colles, no fracture is more frequent; and, from the long-continued weakness of the hand and wrist which it usually entails, none is more important. It is because this secondary condition is unnecessary that I characterize the treatment of which it is the direct result as pre-eminently bad. My criticism applies solely to the splints habitually employed. The reduction of the fragments by extension, counter-extension, and manipulation, the subsequent lateral flexion of the hand to the ulnar side, and the use of anterior and posterior splints with the ulna and radius in parallel position, can not be questioned. It is the prolongation of these splints which is the source of

evil. I believe long splints are generally recommended in the standard text-books of surgery, and I know from my observation of hospital *internes* that their use is taught in the medical schools of New York with perhaps a single exception. It is insisted that immobilization of the wrist is essential to the stable fixation of the radial fragments. Actual experience shows this to be untrue, so that the prolonged and even permanent disability which it causes is gratuitous. The splints should be made of thin deal, a little wider than the forearm, should extend from the elbow to the wrist, leaving both joints free, and should be secured by broad bands of adhesive plaster and, if necessary, by a roller bandage. At the elbow they should allow absolute freedom of motion at the convenience of the patient. At the wrist they should accurately compress the extremities of the radius and ulna, just reaching to the margin of the joint without encroaching upon it. Although the wrist will be unimpeded in action and the hand mechanically unrestrained, the constraint of the forearm and the dependent position of the hand will maintain their absolute quiescence. The freedom of the joint from pressure or interference by apparatus insures its future integrity of action.

If the retentive bands of adhesive plaster are applied in the manner recommended by Dr. J. W. S. Gouley, who first in this country used the short splints for radial fracture, no readjustment will be required except as the subsidence of swelling may demand. In this method the lower band is attached to the inner border of the ulna, carried over the dorsal aspect of the wrist, and then over the anterior splint. The upper band is attached to the anterior surface of the forearm below the elbow and carried over the posterior splint. Each band is made long enough to more than surround the limb. If the bands are simply wrapped around both splints, almost daily readjustment will be required for a week or more on account of the slipping of the apparatus downward. In this event great care should be exercised to avoid disturbance of the fragments.

Any splints which extend below and fix the wrist joint should be denominated *long* and the term *short* restricted to those which leave the joint free. Some confusion in nomenclature exists from failure to make this distinction upon an anatomical basis. Long splints have been made to extend to the metacarpophalangeal articulations, or even to the finger tips. They have also been fashioned in pistol shape as a means of maintaining lateral flexion of the hand, and this point has been much exploited. The smallest experience with straight splints, long or short, demonstrates that the hand once made to assume the proper position will retain it without special care.

The effect of long splints upon the future usefulness of the hand and wrist is so constantly observed as to scarcely admit of question even by the advocates of their use. Months or years often elapse before they are sufficiently restored to easily subserve the ordinary functions of life, and their finer movements, indispensable in certain occupations, are often permanently impaired. It is objected that the short splints do not sufficiently hold the fragments after reduction to obviate the danger of deformity. Experience

and observation must be the sole arbiters in this point of dispute. I have never once treated this fracture in any other way, and I have never failed to keep the fragments in as good position as I was able to obtain in reduction. No splint can do more. This result has been confirmed in the practice of other surgeons who hold similar views. I believe deformity will be really less with this method of treatment, since the bone is more open to inspection, and trifling derangements can be more readily corrected and with less disturbance of the apparatus. There is equal advantage to be gained in the treatment of other fractures of the forearm by not extending the splints below the wrist.

Fractures of the extremities of long bones implicating the joints are always unfortunate in result. The operative procedures which they demand are of great interest, and I regret that the limits of this paper do not permit their consideration. The conditions and methods of interference are of too great importance to justify the merely casual mention to which I should be restricted.

The treatment of compound fractures is another subdivision of the general subject which is too extended for our present limitations of time and purpose. I am less reluctant to turn aside from its discussion since it is already prominent in the literature of aseptic surgery. It may be said to epitomize the methods and possibilities of asepsis as it is practiced at the present time. I can not refrain from contrasting the results in compound fractures of thirty-five years ago and of to-day. Then few escaped without loss of life or limb; now few lives or limbs are sacrificed. The occasional recoveries of unamputated patients which I saw at that epoch were in Bellevue and were mainly attributable to the genius of Dr. James R. Wood, in whose service at the hospital I had the honor to be and whose friendship I shared with all young men in the profession with whom he came in personal relation. His professional sagacity was phenomenal, and, by the maintenance of open wounds, thorough drainage, and the most systematic attention to cleanliness which available means then permitted, he unconsciously anticipated without antiseptic agents the most important part of modern aseptic treatment. It may be of passing interest to mention that impure carbolic acid was in use in that hospital at that time, but as a stimulant, not as an aseptic, and upon ulcers and old granulating surfaces, and not upon recent wounds.

The extraordinary collection of cases published a few years ago by Dr. F. S. Dennis admirably illustrates what is accomplished in the present aseptic care of this class of fractures. They probably underestimate than otherwise the chances of recovery. If those cases are excluded in which complications exist, as well as those in which some crushing violence has primarily destroyed or fatally impaired the vitality of all the structures of the part, failure to preserve the integrity of the limb may be fairly termed exceptional. A possible danger to life, born of aseptic faith, exists in overconfidence of the surgeon and a consequent attempt to avoid mutilation where there is no rational ground for hope. As safety lies in primary amputation, rash conservatism incurs a mortal responsibility. There is no conceivable contingency in which a surgical decision

requires a more delicate appreciation of all the features of a case, studied in the reflected light of past experience, nor in which it should follow a more critical survey of all the elements of the situation. It may even then ultimately depend in great degree upon a professional instinct, not ignorantly innate, but founded upon the unconscious impressions derived from a multitude of previous observations, which upon occasion takes precedence of all formulated rules. If under such circumstances it proves that life has been endangered in the vain effort to save a limb, the intelligent and conscientious discretion which has been exercised and the acknowledged fallibility of human judgment will afford full absolution from responsibility. There can be no similar condonation of the error which comes from technical ignorance and inexperience when wiser counsel can be had. Consultation costs nothing to the surgeon, and may profit much to the patient.

It may happen in a primary amputation, and usually does occur in secondary cases when the condition has become so depreciated as to be unfitted to withstand the effects of shock, that rapidity of operation is literally of vital importance. It can be facilitated by perfection of preparation; the assistants can be so familiarized with the operator's requirements, and his every possible want can be so exactly anticipated, that losses of time can be counted in seconds. I am accustomed to go further than this. The preservation of life is of paramount importance and the severance of the part which imperils it is the only pressing operative necessity. I therefore content myself with doing just this and no more. In such urgent cases I waste no time in forming flaps and have no hesitancy in cutting straight through the limb. If the patient lives, flaps may be fashioned or reamputation made at some more convenient season. I never employ an Esmarch bandage, and consequently have no occasion for a multitude of ligatures. There is no need for sutures or refinements of dressing. Three or four ligatures and a dash of hot water, a compress in the wound, some combination dressing, and a roller bandage over all, are matters of but a moment or two of time if preparation has been adequate. If the arterial trunk has been accurately compressed, if the anæsthetic employed has been nitrous oxide, or if ether or chloroform has not been carried beyond the necessary very moderate effect, shock will be reduced to its minimum. Cardiac and general stimulants can be hypodermically exhibited, hot-water bottles applied to the surface, and even hot-water enemata administered during the progress of an operation. It is the minutest attention to such details as these that makes the difference between life and death, and that has sometimes enabled me to save cases which seemed practically hopeless. I should perhaps apologize for passing by the many serious questions connected with the treatment of compound fractures to linger over the steps of an amputation. I have often observed, however, that things which are quite simple and obvious are most neglected and consequently least understood. I am not sure whether this provisional amputation has been heretofore recommended as a formal operation.

There are two fractures—one of the vault of the cra-

nium, the other of the patella—which, when simple, I usually make compound. This I do in the first for purpose of examination as well as of treatment, and in the second for treatment solely. I am compelled to assume, perhaps erroneously, that my views in regard to these fractures are known, for they have already appeared in print.

In a recent paper upon injuries of the head I referred briefly to fractures of the vault. I recur to them now in order to emphasize some points in treatment which I consider of sufficient importance to admit of iteration. These, in form at least, may be axiomatically expressed. A suspected simple fracture should be exposed by an incision of the scalp for purpose of examination. If a simple linear fracture be discovered, and there be no symptoms pointing to a complication, the wound may be closed. If with a linear fracture there be indications of meningeal hæmorrhage, or of lesion of the brain substance, or if there be an open fissure, trephination should be made for further exploration. If the fracture be depressed, the bone should be elevated, even in the absence of complicating symptoms. The further incision of the dura, or invasion of the brain itself, concerns the management of complications and not the fracture *per se*, and is consequently foreign to our purpose. This series of rules, which I regard as aphorisms, are founded upon a belief in the necessity for the elevation of depressed bone under all circumstances—a necessity so urgent as to demand that the depression should be determined or disproved by any requisite operative means. It has fortunately become possible to institute these exploratory measures without danger to the patient. The validity of the proposition that depressed bone should always be at once discovered and elevated or removed would seem to have been made convincingly clear in the history of numberless cases in which it has been neglected. It is not an occasional but a frequent instance in which, after the lapse of years, epilepsy, abscess, or mania has followed a cranial fracture, and in which a simple depression unrelieved, a cyst, or a spiculum of bone penetrating the brain, has been found to be the cause of an irremediable disease. If the occurrence of immediate danger is to limit responsibility, the surgeon may well allow his patient to drift, while he watches from day to day for the manifestation of primary symptoms, and in their absence for some brief time regard the cure complete. It is not even possible in a majority of cases to repair the evil consequences of such neglect by later operation; the remedy lies in prevention, not in cure. The epileptic habit, or the maniacal condition, once firmly established, the final removal of its cause is too often but an ineffectual resort. I have within the year removed an extensive area of depressed bone and a subjacent cyst in an adult, the result of an injury in childhood, without as yet any marked improvement in an epileptic condition. I offer no suggestion as to the method of primary operation. The employment of the elevator, rongeur, drill, chisel, or trephine is simply a matter of preference or convenience. The fact that a different view of practice is still maintained is simply an additional illustration of the vagaries of surgical opinion.

In the paper to which I have already referred I ex-

pressed an opinion that trephination is devoid of danger. I have feared lest I might have been understood in a broader sense than I intended. I am quite aware that this operation, in cases of chronic organic disease of the brain, is sometimes followed by a fatal result. I have recently trephined in a case of paresis in which I am convinced that death was hastened by interference. I am equally certain that an explorative trephination in a late stage of cerebral traumatism has in two instances been similarly unfortunate, and it is scarcely more than a month ago that, in a New York hospital, death followed trephination for epilepsy. It would not be difficult to multiply examples. In cases of recent fracture or of suspected meningeal hæmorrhage, to which I intended to confine my expression of opinion, I have no doubt of its entire safety. I have never seen any case in which there was the slightest reason to suspect that it had hastened or produced an untoward result. I do not hold the operation responsible for the effects of prolonged etherization, excessive hæmorrhage, or septic poison. It is true that shock from ether and hæmorrhage has proved fatal. If the brain has been crushed, the great venous sinuses wounded, or the larger meningeal arteries torn, much blood may be lost and considerable time occupied in the treatment of the wound; but it is these conditions, and not the operation which they necessitate, which involve danger. In the simpler and doubtful cases—the ones in which exploration or operation has been deprecated—there can be no great difficulty in safely limiting anæsthesia, controlling hæmorrhage, or counteracting the effects of shock. The further possibility of the occurrence of sepsis is not more a factor here than it is in operative wounds in general. If anything may be assumed absolutely, it is the certainty with which surgical cleanliness may be assured where the making of the wound, as well as its cure, is under the control of the surgeon. I have seen cases of compound fracture, originally contaminated or foul from neglect, in which the suppurative process had invaded the brain or its membranes, but I have seen none in which an operation made to convert a simple into a compound fracture, or to open the cranial cavity, has given entrance to the pyogenic germs.

If we consider, then, the serious morbid conditions which often follow a neglect to relieve the brain from bone pressure, and the absence of probable danger which it involves, there seems to be no good reason why fractures of the vault should not be subjected to as critical examination as other accessible injuries, or why practicable measures should not be taken to avert future complications.

The second of the simple fractures which I habitually make compound is that of the patella. Three years ago, at the annual meeting of the Bellevue Hospital Alumni Association, I advocated wiring this fracture as the treatment to be almost invariably adopted, excepting scarcely more than those cases in which organic visceral disease rendered any operative interference inadmissible. My later experience has been for recent fractures entirely corroborative of the statements made at that time. The essential contentions which I then made were: That the obstacle to union is usually the intervention of the anterior capsular

fibers, which fall between the fragments and prevent osseous contact, even though close approximation be effected; that this obstacle can not often be removed by any measure short of opening the joint; that this method is without danger; that its result is invariably osseous within less than half the time required for ligamentous union by other means; that restoration of the function of the joint can be made perfect by sufficient care in after-treatment; and that, when the surgeon possesses ordinary operative skill, it is an operation not of choice but of obligation. I had at that time operated in forty-two recorded cases. I had never lost a life or limb, had never had a drop of pus in the joint, had never failed of osseous union, and had never but once had any ultimately serious limitation of joint movement. Since then I have continued to treat this fracture in the same way with the same results, and have had no occasion to change my views. At that time, only three years ago, the operation was regarded very much as was ovariectomy thirty years previously. No one quite ventured to call it unjustifiable, but almost every one looked at it askance, congratulated himself that he did not do it, and cheerfully awaited disaster to the occasional man who did. As a gentleman expressed it at a meeting of the Surgical Section of the Academy of Medicine, he treated fractures of the patella without operation, and could sleep undisturbed at night. In this brief interval I have noted with pleasure that an increasing number of surgeons are able to so treat this fracture as to gain the best results without the loss of rest which an uneasy conscience or lack of self-confidence seems to entail.

It will be unnecessary to recapitulate the steps of operation, which I have since modified in only one or two particulars. I have discarded the use of strong antiseptic solutions. I began with a bichloride-of-mercury irrigation of 1 to 5,000. I afterward reduced its strength to 1 to 10,000, with some misgivings as to its safety. I now use a solution of 1 to 20,000 in boiled water. I have no reason to doubt that boiled water by itself would be as sufficient here as in the larger serous cavity of the peritonæum. I add the modicum of antiseptic salt as a perhaps unnecessary precaution lest the joint cavity should suffer some casual contamination during operation. I find that by this avoidance of strong antiseptics the subsequent restoration of movement in the joint is much more easily accomplished.

I continue the use of a single articular drainage-tube merely to afford an exit for post-operative hæmorrhage. I have long since ceased to fear the occurrence of purulent synovitis. I regard superficial suppuration, however, as quite possible whenever there has been much laceration of the soft parts; but if the deep sutures have been carefully placed and superficial drainage provided, there is not the slightest danger that pus will enter the joint.

In the second stage of treatment, after union has become sufficiently firm to render manipulation safe, the same advantage is to be derived from systematic massage that has been noted in fracture near the extremity of a long bone. There is the same necessity also, if it is to afford the greatest possible advantage, that it should be applied

by a professional person who possesses technical skill and experience. Since I have discarded antiseptics of more than nominal strength, and have employed a masseur in cases where the joint is of more than usual rigidity or where it readily inflames by the use of passive motion, I have had much less trouble in restoring natural function.

The proper treatment of recent fracture of the patella is, in my mind, quite clear and well determined, but what to do with the fracture which has existed for a longer time is often difficult to decide. It is such cases which are most likely to come from a distance for relief, and they are certain to include all those most unfit for operation. The conditions which militate against success are mainly three—the contraction of the quadriceps extensor muscle, the atrophy of the lower fragment, and the shortening of the ligamentum patellæ. The muscular contraction can be overcome by massage, and is consequently unimportant; the atrophy of the lower fragment is irremediable; but it is the shortening of the patellar ligament which renders many cases hopeless. Unless the fragments can be brought into at least partial contact, operation will be worse than useless. The length of time which has elapsed is important, but not absolutely determinate. At the end of two years I have obtained entire contact without difficulty or preliminary treatment. At the end of a few months even partial contact has been impracticable. In all cases the length of the quadriceps extensor should be restored, and the ligamentum patellæ, if possible, elongated by preliminary manipulation. Contact may be deceptive from portions of ruptured ligament which remain attached to the bony fragments. Operation, therefore, should not be ventured unless the fragments can be so readily brought together as to enable some allowance to be made for this source of error. There may be a single exception made to the rule. If there be absolute non-union, so that the whole joint cavity be subcutaneously exposed, flexion as well as extension impaired, and the limb so weakened as to justify occasion fear of fracture of the opposite patella, it may be well to operate even if doubt exist as to the nature of contact, and even at the risk of an ankylosed knee. If no contact at all be had, protection of the joint cavity will be lost and trouble probably arise from some form of synovitis. Old fractures of the patella at best are as troublesome and unsatisfactory after operation as recent cases are tractable and perfect in result.

There is an operation which has been recommended in place of wiring, and which has for its object approximation of the fragments by means of a subcutaneous suture. It is radically defective because it fails to secure osseous union. It does not provide for the removal of intervening capsular fibers, and has consequently no advantage over a plaster apparatus except in making approximation closer. It is quite as difficult to do as the radical open operation, and would seem to be quite as likely to be followed by superficial suppuration.

The consideration which I have been able to give to the several fractures mentioned has been of necessity hasty and imperfect. I have already disclaimed any intent to make either a systematic or an exhaustive study of the general

field in which they occur, and have sought only to emphasize some facts and observations which have impressed me with special force. I have spoken with some positiveness and insistence because my personal observation has led to positive convictions, and because I know that exact truth always loses by indirectness of expression.

34 WEST THIRTY-SEVENTH STREET.

REASONS FOR REMOVING ABDOMINAL TUMORS.

By F. BYRON ROBINSON, B. S., M. D.,

CHICAGO,
PROFESSOR OF GYNÆCOLOGY IN THE CHICAGO POST-GRADUATE SCHOOL;
GYNÆCOLOGIST TO THE WOMAN'S HOSPITAL, CHARITY HOSPITAL,
POST-GRADUATE HOSPITAL, AND COLUMBIA HOSPITAL.

SPECIAL study in the physiology and pathology of the viscera develops reasons for the removal of abdominal and pelvic tumors not apparent from superficial observations. It is well known that shortly after the appearance of a tumor in the abdomen the health of the patient becomes more or less impaired. The functions of the organs become deranged; the heart suffers from abnormal action and structure; the digestion becomes more or less deranged. As the tumor increases in size, kidney diseases generally develop. The liver, forming bile, glycogen, and urea, sooner or later becomes impaired in its rhythm.

The lungs lose their rhythm and become spasmodic, while the spleen shows its disturbance by pigmentary deposit on various portions of the body. An attempt will here be made to explain the pathological result of abdominal tumors on physiological and anatomical grounds.

The basis of the explanation will be by reflex action on the sympathetic nerve. It may be curtly observed that the pathology of the sympathetic nerve in health and disease is reflex action. An ideal nervous system consists of (a) a ganglion cell, (b) a conducting cord, and (c) a periphery. The sympathetic nerve possesses all these in an eminent degree. We will assume that the ganglia which are found in the sympathetic nerve, especially the abdominal brain and the three cervical ganglia, are points where forces are reorganized and redistributed to the viscera. The first essential feature to observe in the diseased viscera is the disturbance in rhythm. Though any abdominal tumor may produce the same results, we will choose a uterine myoma to illustrate our views. It is a principle in physiology that when a peripheral irritation is sent to the abdominal brain the reorganized forces will be emitted along the lines of least resistance, so that the organ which is supplied with the greatest number of nerve strands will suffer the most. Practically this principle holds true in every viscus.

The effects of the tumor on the heart may first be considered. An abdominal tumor induces fatty degeneration of the heart. Where the uterine tumor irritates the peripheral ends of the hypogastric plexus the irritation is transmitted to the abdominal brain and there reorganized and emitted along the splanchnics to the cervical ganglia, where a reorganization occurs and the force then passes down to the heart by way of the three cardiac nerves. The irritation could pass directly from the uterine myoma up the lateral chain of sympathetics to the three cervical

ganglia, when it becomes reorganized. It no doubt transmits part of the irritation by way of the abdominal brain and part by way of the lateral chain; so far as the heart is concerned, the result is nearly the same, for the irritation is reorganized in each case in the three cervical ganglia and transmitted to the heart. It is of course necessary to consider that the irritation may be sent to the spinal cord by way of the vagus and there reorganized; it is sent directly to the heart by the vagus.

The first manifest objective heart symptom is irregularity. The irritation from the uterine myoma reaches the heart in two ways:

1. The irritation passes up the hypogastric plexus to the abdominal brain, where it is reorganized and emitted to all the viscera over their respective sympathetic plexuses. In the case of the heart it passes up the abdominal splanchnics to the three cervical ganglia of the sympathetic, where it is reorganized and sent directly to the heart.

2. Some of the irritation is transmitted by way of the vagi to the medulla, where it is reorganized and sent directly to the heart by the cardiac nerves which supply the heart from the vagus. This is more especially the case in the right vagus, as that is the cranial nerve which largely supplies the heart and abdominal brain. Now, this irritation from the myoma goes on day and night. It gives the heart no rest; it flows on to the heart in the midst of a diastole or a systole. The first great characteristic of the heart rhythm is lost. Having lost its rhythm, the heart proceeds irregularly. Irregular action means a changed nourishment; continued irritation with disturbed rhythm induces the heart to overfeed itself, the result being hypertrophy. It may be noted that this hypertrophy is not brought about in precisely the same way that hypertrophy from valvulitis or aortic insufficiency is, but vaso-motor dilatation must play a rôle in overnourishing the cardiac muscles. It resembles more nearly the cardiac hypertrophy existing in goitre. The cardiac hypertrophy from the reflex irritation in myoma is also a moderate hypertrophy so far as the writer has observed, and it is a very slow process. In the first stage the heart becomes irregular, in the second hypertrophied, in the third stage the heart takes on fatty degeneration. Fatty degeneration of the heart is no doubt a preservative process, so that a large, vigorously beating heart will not rupture an artery in a degenerated state (atheromatous or fatty). It appears certain that many old cases of large uterine myoma are lost after skillful operations simply from fatty degeneration of the heart. It is common to observe palpitation in patients having uterine myoma, and a palpitating heart is the characteristic symptom of a weak one.

The automatic cardiac ganglia are disturbed by reflex irritation and take on an excessive nourishment. The irritation, sent to the heart over the hypogastric plexus, is in one sense an increased demand for action. The irritation, passing to the heart day and night, winter and summer, according to a physiological law, provokes hypertrophy if the nutritive powers are good. If the nutritive powers are not good, the complementary half of hypertrophy results in dilatation.

A fatty degenerated or a weak heart induces low blood pressure, and is the bottom factor in waste-laden blood and deficient eliminations. It allows local congestions and consequent impaired nourishment. The logical force of such circumstances teaches to remove uterine and other abdominal tumors as early as possible, so that the patient will not be left with partially or completely damaged viscera.

Reflexes arising from the irritation of the sympathetic in the peritoneal membrane are profound in results. Irregularity, hypertrophy, and degeneration of the heart is a reflex act accomplished mainly through the sympathetic system due to irritation at the periphery of the hypogastric plexus being transmitted to the abdominal brain, the three cervical ganglia, and some to the spinal cord, whence reorganization of the forces occurs.

The reorganized nervous impressions then pass to the heart over the six cardiac sympathetic and the six cardiac vagi nerves. This abnormal force deranges the fine balance of the heart's rhythm. The automatic cardiac ganglia become disordered, which in time disturbs vaso-motor action and consequently nourishment.

Abdominal tumors induce fatty degeneration of the liver. It may be asserted that an influence on the hepatic plexus of the nerves alone could stop all secretion in the liver. If such a proposition be true, it need not be wondered that lesser irritations on the hepatic nerve plexus could so alter the secretion of the liver that it would degenerate the organ. The characteristic disturbance which arises from the uterine myoma is to derange its rhythm. The liver has a rhythm due to (a) an elastic peritoneum inclosing it, (b) to an elastic capsule (Glisson's) surrounding it, and (c) to the capacity of its cells to enlarge.

The occasion of the liver rhythm is food carried to it by way of the portal vein. When the peritoneal and Glisson's capsule and the cells are expanded to a maximum, the liver rhythm is at its climax.

Now, the products of the liver (bile, glycogen, and urea) are sent to their respective homes by the elastic peritoneum and the elastic capsule of Glisson contracting. The liver then gets its rest and repair.

The irritation from the periphery of the hypogastric plexus passes up to the abdominal brain, where it is reorganized and emitted to the liver. The irritation goes to the liver at all hours from the tumor and deranges its rhythm. The irritation may vainly attempt to induce a rhythm without food, or it may flash on to the liver at any stage in the rhythm. The liver rhythm is induced by the automatic hepatic plexus. So that it may be asserted that the irritation of the uterine myoma deranges the rhythm of the liver. The second point to consider is the altered secretion in the liver, due to the reflex irritation from the uterine myoma by way of the abdominal brain. The products of the liver are bile, glycogen, and urea. The secretions may be changed in three ways by the irritation: 1. The secretion (bile, glycogen, and urea) may be too much. 2. The secretion (bile, glycogen, and urea) may be too little. 3. The secretion (bile, glycogen, and urea) may be disproportionate.

In any case the function of the liver will be impaired,

and the continued irritation increases the derangement. The irritation soon changes and impairs the liver nourishment. The complete process from food to end products becomes imperfect, and a lower grade of tissue is formed, known as fat. The constantly irritated liver soon becomes unable to form but little products beyond fat, and degeneration follows.

It is well known that women at the menopause frequently acquire liver disease. It is owing to reflex irritation through the abdominal brain. The degeneration of the hypogastric plexus will not allow it to transmit the physiological order over it to induce a monthly rhythm, so the accumulated energies flash on to other organs, and the liver is especially manifest, because its derangement is often followed by pigmentation (yellow or brown and black) of the skin. The uterine myoma then, by reflex action, disturbs rhythm and secretion in the liver, and so its nutrition. It ends in fatty degeneration.

(To be continued.)

TRANSILLUMINATION OF THE MASTOID CELLS AS A MEANS OF

DIAGNOSIS OF MASTOIDITIS INTERNA SUPPURATIVA.

By GEORGE W. CALDWELL, M.D.

WHEN we consider the serious nature of confined pus in the mastoid cells, the frequency of death from meningitis, thrombo-phlebitis, or metastatic abscesses resulting from recognized or unrecognized cases, the gravity of the operation for its relief, and the occasional operations which are done on a mistaken diagnosis in which no purulent collection is found, it is apparent that any means by which we may diagnose this disease with greater accuracy will be worthy of our careful attention.

Such a means will be found in the miniature electric lamp, and the conclusions to be deduced therefrom will be based upon the fact of the diaphanous nature of healthy mastoid cells and the opacity of pus; and the auxiliary proposition that however mastoids may differ in size, shape, and thickness, and therefore in transilluminability, they are practically at least the same on the two sides of a given head, thereby affording an easy and accurate basis for comparison.

The apparatus required is a battery which will develop about ten volts—roughly speaking, a five-cell battery—regulated to light well, but not burn out, a two or three candle-power electric lamp of very small caliber (supplied by Meyrowitz, East Twenty-third Street, New York), this being protected by thin rubber tubing fenestrated at one side and made to fit snugly at the meatus by a washer of larger tubing.

In a perfectly dark room the lamp is inserted well into the external auditory meatus, the fenestra directed backward, and the current made. Instantly the healthy mastoid is illuminated with a ruddy glow extending from the apex to the lateral sinus and to the limits of the cells above. The reverse manner may be more satisfactory in a given case, as when the canal is small, obstructed, or pain-

ful, and may be used with a larger lamp. A speculum of large size being placed as for examination of the membrana tympani, the electric lamp, incased in a rubber tubing projecting slightly beyond the lamp, is pressed against the mastoid and the current made, when the external auditory and middle ear will be filled with a rosy light from the posterior wall.

By placing the lamp on different portions of the mastoid the limitations of the cells and the position of the lateral sinus may be accurately mapped out, and the particular region in which a pathological process exists demonstrated. If the cells are occupied by a purulent collection, the glow will be absent and the cells will be dark. Comparison with the opposite healthy side renders the diagnosis of pus in the mastoid cells complete, whether or not the usual symptoms are present, for suppurative mastoiditis may exist without external indications, which, indeed, is the most dangerous form, as the process tends to extend inward, not outward.

D. Milton Green (*Journal of the Am. Med. Assoc.*, November 12, 1892) mentions five cases in which none of the external signs were present, no tenderness, pain, or swelling, yet pus was found either on the operating table or at the autopsy. Knapp has reported a fatal case (*Arch. of Otolaryngology*, July, 1892, page 239) in which no discharge from the ear ever occurred. In a series of eighty cases reported by J. Orne Green, of Boston (*Journal of the Am. Med. Sciences*, 1890, page 575), thirteen per cent. showed no external signs, yet confined pus was found. (See also report of forty-seven cases operated upon in Mount Sinai Hospital, New York, by Dr. Gruening, *New York Med. Jour.*, January 2, 1892.)

Frank, developed cases are easily recognized, but the classical indications of Schwartz or of Körner, quoted with more or less modification in every text-book of otology, are of uncertain assistance in deciding a doubtful case. The method which I have herein submitted is scientifically accurate, easy of application, painless, strikingly pictorial, instantly decisive, and demonstrable to the patient's friends.

339 WEST TWENTY-THIRD STREET.

OZONE IN THE TREATMENT OF DIPHTHERIA.

WITH REPORTS OF SEVEN CASES.

By IRVING S. HAYNES, Ph. B., M.D.,

DEMONSTRATOR OF ANATOMY, UNIVERSITY MEDICAL COLLEGE;
MEMBER OF THE SOCIETY OF THE ALUMNI OF BELLEVUE HOSPITAL, ETC.

THE histories of the following cases are given for the reason that they are typical cases, that they recovered, and that their recovery, I consider, is due in great measure to the powerful germicidal action of a new ozone preparation—therapol—to which I wish to call the attention of the medical profession.

Of the seven cases, six were so severe that had death occurred in any one, or all, it would not have been unexpected. That such a termination did not result, I believe, is due to the action of the remedial measures employed.

A summary of the treatment in full follows the clinical reports of the cases.

The parts involved in the diphtheritic process, as shown by the production of membrane, were as follows:

Case I, right tonsil; Case II, tonsils, pharynx, nose, and larynx; Case III, tonsils, pharynx, and nose; Case IV, larynx; Case V, tonsils, nose, and larynx; Case VI, tonsils and nose; Case VII, pharynx.

CASE I.—Lafayette L., aged three years and a half. First call, November 29, 1892. Child feverish; temperature, 101.5°. On examining throat, pharynx and soft palate red and swollen; tonsils also swollen and inflamed. Right tonsil covered with membranous patch, oval in shape, about half an inch in its long diameter.

Treatment.—By ordinary methods, fluid extract of gelsemium; disinfectants, as menthol, carbolic acid, and spirits of turpentine in boiling water, renewed frequently; iron and glycerin internally; Platt's chlorides for the room. The iron solution, turpentine in boiling water, and Platt's chlorides were used in all the cases cited.

November 30th.—Dr. Quimby, who had been physician to the family when they were living down town, called in consultation. He suggested the use of therapol, an ozone preparation of which I had heard nothing. Therapol was accordingly sent for and used, by swabbing the throat every hour and also syringing out the nose with same once in two hours. The case went rapidly on to recovery. Last visit was made on December 6th. Child had thoroughly recovered; the membrane disappeared from the throat in about forty-eight hours. At no time was there involvement of the nose or larynx.

CASE II.—Harold S., aged four years and a half. Called first on December 18, 1892. Child had been ailing for two or three days. Its parents thought it nothing but a slight cold. On investigation of the case, found the child feverish; temperature was not taken. The face was flushed. The throat, on inspection, showed the fauces, pharynx, and soft palate deeply swollen and inflamed. The tonsils were swollen so as almost to meet, and were covered on both sides with a thick, grayish membrane. Child could not breathe through the nose, from which a thick discharge escaped. All possible precautions were taken; the turpentine mixture with boiling water and Platt's chlorides as disinfectants; mixture of chloride of iron given internally and applied locally. This was all that was done at that time. Morning of the 19th, no change for the better. Nose completely blocked up, and foul crusts show protruding through the nostrils; whitish streaks in the pharynx; is getting hoarse. In addition to the foregoing remedies, therapol was sent for, throat was swabbed every hour, and the nose syringed with it every two hours. In syringing the nose a blunt-pointed glass syringe, holding about a drachm, was used. Half a syringe of the therapol was injected into each nostril. Lime was also constantly slaked in the room.

December 20th.—Nose and throat clean. Child can breathe freely through the nose; patches entirely removed from the tonsils and pharynx, but both are red and inflamed. On account of the weak heart, whisky was given freely. Hoarseness increased so much that intubation was considered. Dr. Joseph O'Dwyer was called in consultation at 5 p. m. Dr. O'Dwyer suggested calomel fumigations, ten grains to be sublimated every two hours for the first twenty-four hours, every three hours for the second, and every four hours for the third twenty-four hours, while the child was confined in a tent of blankets over his crib.

21st.—Nose and throat clean, breathes easier, and takes nourishment.

22d.—Steady improvement.

23d.—Made last visit; case convalescent.

CASE III.—Boy, about four years old. Seen with brother physician on January 21, 1893. History of the case: Child has been sick about a week with scarlet fever; at present there is a profuse rash over the entire body. Throat, tonsils, and pharynx very much swollen and injected; very foul, grayish membrane covering nearly the entire surface; nose completely blocked by a similar membrane. Temperature between 103° and 104°; pulse very rapid and weak.

Diagnosis.—Diphtheria complicating scarlet fever.

Prognosis.—Very bad; recovery not expected. Doctor has been using all the remedies, including peroxide of hydrogen, without any appreciable benefit. I suggested the use of therapol, to be used on a swab for the throat and to be injected into the nose. Saw the doctor after a few days, and he said that the therapol had promptly cleaned off the membrane from the throat and nose. Child recovered finally. In addition to the local treatment, the doctor had used every means for keeping up the strength of the child and combating the disease.

CASE IV.—Flora K., two years of age. First visit on February 14th. Has been sick two or three days with croup. Child is running around the room, stopping every little while to lean up against a chair to rest; inspiration crowing can be heard in the adjoining room. Examination shows gland of the neck swollen, tonsils swollen, follicles are full, pharynx red and swollen; nose is fairly free, though somewhat occluded.

Diagnosis.—Tonsillitis, pharyngitis, and laryngitis; probably diphtheritic, although no membrane has appeared, but from the fact that her sister had just died of diphtheria after only three days' illness and lay in the next room, it is pretty sure to be diphtheria. Her mother said that the membrane had formed in the nose and throat of the sister, and finally suffocated the child, who had had croup-like this one.

Prognosis.—Doubtful.

Treatment.—Calomel fumigations, as recommended by Dr. O'Dwyer in preceding case, poultices to the neck, therapol applied locally every hour with a swab to the throat, and the nose syringed every three hours with Carl Seiler's antiseptic pastils in an aqueous solution. Disinfectants and steaming were also used. Convalescence followed. Child entirely recovered by the 19th.

CASE V.—Ida B., aged four years, was taken sick on April 21st; was seen on the morning of April 22d. Child feverish, face flushed; temperature was not taken. Inspection of throat shows pharynx deeply inflamed, both tonsils swollen so as nearly to meet, and covered with a very thick, grayish membrane. Child can breathe through the nose, but breathing is very difficult. Glands behind angle of jaw swollen.

Diagnosis.—Diphtheria.

Treatment.—Similar to the other cases. The administration of the iron solution every hour, swabbing the throat every half hour with therapol; injection into the nose of small quantity (fifteen to twenty drops) every two hours. The use of the disinfectants for the atmosphere—chlorides and turpentine in boiling water. Case progressed slowly; membrane cleared off from right tonsil by the 25th. The nose was clear at this time, but, some hoarseness developing, calomel fumigations were resorted to.

April 26th.—Not quite so hoarse; calomel continued. Right tonsil clean.

28th.—A. M., patch very thin on left tonsil. At 3.30 p. m., only a little spot left. Patient was from this time much easier. Fumigated once in four hours; therapol used once an hour instead of every half hour. After the 26th the child was only awakened every hour at night, when she was given iron, and then the throat was swabbed and nose injected with the therapol. Nothing to drink was given for fifteen to twenty minutes after

using the therapol, in order to have its local action as long as possible.

30th.—Child convalescent. She recovered completely.

CASE VI.—Ida D., aged five years. First call April 25th. Child was taken sick on the 23d. On the 24th the mother noticed patches in the child's throat.

April 25th.—First visit. Found the child's throat badly swollen, the tonsils and soft palate covered with a grayish membrane; cervical glands very much enlarged and painful. Child feverish, face flushed, and pulse rapid.

Diagnosis.—Diphtheria.

Treatment.—Iron solution internally and the therapol locally every hour alternating; turpentine mixture in boiling water also used, and disinfection with chlorides fully carried out. In the evening nose completely stopped up; right tonsil somewhat cleaner; left has a dark-greenish patch. Same treatment was continued; in addition, the therapol was injected into the nose every hour.

26th.—Tonsils clean below, but upper part of the throat looks about the same. The child's throat continued to improve more rapidly than her nose did. The nose was not completely clean until May 2d. Discharge from the nose was the foulest discharge I ever saw, and the odor from the patient's throat was offensive until I began the use of the therapol. The injection into the nose was kept up day and night. The nose bled very frequently and the therapol acted as a styptic to check the bleeding. The therapol was the only thing that seemed to relieve the nose at all. An alkaline antiseptic solution was tried at the commencement, but, as it only produced pain and did not have any effect upon the discharge, therapol was substituted. One of the beauties of therapol is that it can be used with children of any age, injected into the nose; and the throat is also reached without causing any suffering whatever; its use is absolutely painless. Children that are old enough to talk say that it does not hurt them at all.

CASE VII.—Blanche D., sister of the above-named patient, was taken sick April 27th. Treatment the same as foregoing. The patches did not form on her tonsils, but on the posterior wall of the pharynx, which, as far as one could see, was covered with patches, grayish white in color. Her nose was free, but, in order to prevent nasal complication, the treatment was carried out as in her sister's case, with the result that her nose at no time was affected, and the membrane did not reach further down the throat, but was kept right at that one spot until it was finally cleared off. She was entirely recovered by May 4th.

Summary of Treatment.—When possible, choose a medium-sized, well-lighted room that can be shut off from the rest of the house.

Ventilate the room by having a window open top and bottom at least three inches (more if possible).

Remove all useless furniture. Exclude all visitors. Allow only parties taking care of patient to remain in the room.

Disinfection.—Make a ten-per-cent. solution of Platt's chlorides in water. With this solution freely sprinkle the floor and bedding and keep some standing in the vessels used by the patient for purposes of defecation and expectoration. Handkerchiefs and all clothing from the patient are to be soaked in the above solution or boiled at once for half an hour. Hang up several towels, wrung out of the solution, on cords stretched across the windows and doorways. Every two hours pass through the room waving one of these dampened towels, so as to thoroughly disin-

fect the atmosphere. Keep the air of the room moist and saturated with turpentine vapor by having a pan of water constantly boiling on a gas or oil stove and adding to the boiling water every hour or oftener a teaspoonful of spirits of turpentine, or the following formula may be used instead:

R Menthol..... 3 ss.;
Acid. carbolic..... 3 iv.;
Spts. terebinth..... 3 iv.

M. Sig.: One drachm every half-hour or hour, in the boiling water.

The diet must consist of milk, beef tea prepared from fresh meat, eggs, and later the farinaceous foods, as rice, farina, and corn starch.

Medication, Local.—For the local treatment of diphtheria nearly everything having an antibacterial action has been tried, yet the death rate remains about the same, varying not far from thirty-three per cent.

The seven cases just mentioned are all that have come under my treatment during the past winter, consequently no fatal cases are suppressed.

Cases II, III, IV, V, and VI I expected might prove fatal, and so informed the parents, but, fortunately, none of them terminated in that way. I can only attribute this good result to thorough ventilation, disinfection, and the powerful local antibacterial action of an ozone preparation called therapol. Therapol is a vegetable oil carrying ten volumes per cent. of ozone, according to the analysis of Professor Witthaus. It does not attack healthy tissue, therefore causes no pain. Being perfectly unirritating, it can be applied to the most sensitive mucous membrane without causing discomfort. Consequently a child's throat may be swabbed and its nose syringed every half-hour if necessary. As there is no suffering, there is no screaming or struggling, so exhausting to the child when it has no strength to spare.

To apply the therapol to the throat, a swab made of a pine splinter six inches long, wound with absorbent cotton on one end, answers every purpose. The cotton is to be thrown away after using and the stick kept in a solution of carbolic acid.

To syringe the nose, use a blunt, conical-pointed glass syringe holding about one drachm.

Inject from fifteen to twenty minims of the therapol into each nostril of the child, keeping the child on its back. This favors the running of the ozonized oil back into the throat, securing thorough disinfection of the entire nose and throat.

Small children will swallow the oil that reaches the throat, but, as the oil is not injurious, it does no harm; it is rather the reverse, and will help to keep the stomach aseptic.

In addition to the therapol it is well to have the older children gargle with the usual iron mixture:

R Tr. ferri chlorid..... 3 j to ij;
Glycerin..... 3 iv;
Sat. sol. potass. chlor..... 3 iv.

M. Sig.: 3 j gargle.

The foregoing comprises the local treatment in cases where the nose and throat are involved. By it the mem-

brane will be dissolved and removed in from eight to forty-eight hours, depending upon the severity of the attack. The nose can be kept free if uninvolved; but if already infected, can be cleaned out in about the same time as the throat.

In those cases where the larynx is involved, in addition to the foregoing treatment, calomel fumigations, as recommended by Dr. O'Dwyer in Case II, must be used.

The symptoms that call attention to the larynx are hoarseness, loss of voice, croupy inspiration. In order to detect any hoarseness get the child to speak, if old enough; if too young, notice how it cries.

At the very first symptom (hoarseness) lose no time, but begin at once the calomel fumigation.

Ten grains of calomel should be sublimed every two hours for the first twenty-four hours, every three hours for the second, and every four hours for the third twenty-four hours.

Nothing elaborate is needed to carry out the fumigation. With a woolen blanket construct a tent over the child, in a crib or bed or on two chairs (placed front to front, with a pillow on the seats for the child to lie upon, and a broom handle across the top for a tent pole).

Under the tent place a small alcohol lamp in a deep dish, across the top of which a strip of tin three inches wide is laid. Upon the tin place the calomel, and so adjust the flame that it will take about eight minutes to vaporize the calomel. Leave the child under the tent for five minutes longer.

The first fumigations will prove the most difficult. The child will scream and try to get away, but by coaxing or having a member of the family go under the tent with the child, the fumigation can be carried out successfully.

It is remarkable what relief follows the fumigation. After the first battle the children usually go to sleep while under the tent.

If, in spite of every measure, the larynx becomes so filled up as to obstruct inspiration to any extent, intubation must be performed and the same treatment continued.

Constitutional Measures.—Besides every means for keeping up the strength of the patient by concentrated nutriment, nothing gives any better satisfaction than the iron, glycerin, and potash solution before given. It has a powerful astringent local and a tonic constitutional effect. A drachm of the solution may be given every one or two hours.

Whisky judiciously used is a sheet anchor in tiding over critical cases with threatened heart failure. It must be given in sufficient quantity to produce the desired effect without much reference to the age of the child. It is astonishing what quantities children need.

In Case II, a delicate boy four years and a half old, at one time took a teaspoonful of old Pepper whisky every half-hour for one night. This only served to bring a weak, rapid, irregular pulse of 130 per minute down to a full regular pulse of 90 and keep it there. The following day the interval of time was doubled, and then finally the stimulant gradually stopped in the course of three days, and Tokay wine substituted.

Do not give whisky unless indicated, but when necessary use it freely.

One or two injunctions in closing: Keep up your treatment day and night; in no case let an anxious parent's solicitude for its child's sleep interfere with your treatment. The child will sleep, but the bacilli are wide awake and the formation of ptomaines and membrane goes on uninterruptedly.

Another thing: Remember diphtheria is a giant. Do not waste valuable time in feints, but deal it as many and fast "knock-out" blows as possible.

316 EAST EIGHTY-SIXTH STREET, NEW YORK.

REPORT OF TWO AUTOPSIES

ILLUSTRATING THE COMPLICATIONS OF CARDIAC DILATATION.

By A. L. BENEDICT, A. M., M. D.,

BUFFALO.

CASE I.—Mrs. K., aged forty-five, had been treated at the Fitch Dispensary for some three years for valvular disease of the heart with dilatation. She was a washerwoman of good habits, but overworked for several years. In the winter of 1891-'92 she was sent to the General Hospital, where her uterus was curetted on account of granular endometritis, and a lacerated cervix and perineum restored. For several months afterward she was under the care of a medical student, who kept her on various cardiac tonics. About two weeks before death I was asked to take charge of the case again. It was evident that death was imminent, and a careful examination was impracticable. The heart was dilated, aortic direct and aortic regurgitant murmurs were heard as they had been at the dispensary, and apparently a tricuspid regurgitation was also heard. The word *apparently* is inserted not because of any departure of the murmur from the typical description, but because I would not make a positive diagnosis of any such uncommon condition without the verification of an autopsy. Later moist râles were heard in the lungs, and there was some dullness posteriorly in the lower lobes. The patient required most careful feeding with liquid and, to some extent, predigested foods. Chronic gastritis was diagnosed. It was an open question whether the venous stasis in the liver and kidneys had resulted in an actual inflammation or not.

The post-mortem section was made by Dr. W. H. Bergtold, twelve hours after death. Rigor mortis marked; body fairly well nourished; about one centimetre of preperitoneal fat; some oedema of the abdominal wall. Diaphragm reaches the level of the fifth rib on right side, sixth space on left, showing that there is no particular displacement of the viscera.

Anterior edge of right lung slightly adherent; adhesions more marked posteriorly; very firm at apex. Left lung universally and firmly adherent. Both lungs cedematous, particularly the right. Little injection or other evidence of active hyperæmia or inflammation.

Apex of heart at sixth rib; outer border of heart one or two centimetres to the left of the nipple line. Visceral pericardium thickened into a milk spot, about two centimetres in diameter. Several petechiæ on heart. Pulmonary valve normal, artery admitting two fingers. Aortic leaflets thickened and calcified; aorta extensively atheromatous. Tricuspid leaflets hypertrophied; orifice dilated. The mitral valve has a short left leaflet and a long right leaflet. Both leaflets somewhat thickened. Some fatty degeneration of the papillary muscles, of one in particular. One papillary muscle has its attachment to the inter-

ventricular septum, near the aortic valve. Left ventricle, one centimetre and a half in thickness, about normal. Right ventricle, four to seven millimetres in thickness, in most places normal, but in some spots much thinner. The heart, without blood, weighs five hundred and fifty grammes. No ante-mortem clots, coinciding with the statement of the family that death was quite sudden at the last.

Liver of about two thirds the normal size, firm, mottled, and beautifully nutmeg in appearance. It is cirrhotic, with marked fatty infiltration.

Spleen hard and lobulated, with evidence of old perisplenitis gluing the lobes together and extending inward so as to cause thickening of the trabeculae.

Little perinephritic fat. Left kidney almost "floating." It is "pig-backed"—a shape which Formad has connected with the chronic congested kidney of drunkards. In this case there is not the history of alcoholism, nor is marked congestion noted post mortem. The capsule strips with considerable difficulty. The right kidney is smaller, more congested; the capsule strips harder. Diagnosis: Chronic diffuse nephritis.

Stomach shows chronic catarrh, with moderate dilatation; atonic, not obstructive. Slight ascites.

The pelvic organs are normal, except for the evidences of the operative interference and a relaxed state of the ligaments, with slight uterine prolapse.

CASE II.—B. M., aged forty. The patient was first seen by me a month before death. He was then suffering with broncho-pneumonia, with a history of cough and general prostration of several months' duration, so that the tentative diagnosis of phthisis was made. The heart was somewhat enlarged, and there was a mitral regurgitant murmur, but the pulse was fair, the capillary circulation good, so far as could be judged from the appearance of the skin, and compensation seemed to have been effected for the valvular leakage. The broncho-pneumonia soon cleared up, except that a slight bronchial catarrh remained. The weakness persisted without assignable reason. At midnight of March 1st the patient unexpectedly died. No physician was present, but death was so gradual that the relatives could not tell whether it had occurred or whether the man was in a trance.

Autopsy sixteen hours after death; section by Mr. Jennings, C. M. Body well nourished; rigor mortis marked; fat abundant, but not excessive; no significant external markings.

Left lung everywhere adherent, very much congested and œdematous; slight bronchitis. Right lung free, not so much congested, but more œdematous.

There is a considerable deposit of fat in the pericardium, which is otherwise normal. About 75 c. c. of serum in the pericardium. On the right ventricle there is a white patch in the shape of an isosceles triangle, 4×2 ctm., indicating a former pericarditis. Cardiac apex rounded; ventricular walls hypertrophied and moderately dilated. The right auricle is enormously dilated and thin, containing a white clot as large as a hen's egg. The tricuspid and pulmonary valves are normal; the posterior leaflet of the mitral valve irregular in outline from an old endocarditis (there was a mitral regurgitant murmur). Marked calcareous degeneration in one of the pouches of Valsalva, and some atheroma of the aorta, but without calcareous deposit. These aortic lesions are not so situated as to cause a murmur. Ante-mortem clots in all the heart cavities, corresponding with the history of slow death.

Liver slightly enlarged; nutmeg; slight fatty infiltration, becoming marked posteriorly on the left lobe. Gall-bladder full of bile and inclosed laterally by the liver, instead of lying in a shallow groove beneath it. This condition is probably due to the downward growth of the liver.

Kidneys of normal size, somewhat lobulated, and congested. Capsule strips with some difficulty, but without tearing off the renal tissue.

Spleen small and tough, presenting superficially a triangular area about 2 ctm. in diameter of dense white tissue supposed to represent an old infarction.

Colon small and contracted. Intestine otherwise normal.

Contrary to expectation, the stomach shows no marked lesion.

These two cases illustrate the closing scene of cardiac dilatation due to valvular disease. We may assume the other lesions to be sequela. Just why these patients should have had endocarditis is not apparent. Neither gave a history of rheumatism, except as that word applies to the vague aches and pains in the limbs which most laboring people, and indeed others, have. In both, whatever renal disease existed was apparently the result, not the cause, of the heart trouble, and there was no evidence of arterial fibrosis to indicate a combined circulatory and renal lesion. Without the history of any distinct toxæmia we may ascribe the endocarditis to the dyscrasia which accompanies overwork and exposure. At the same time it must be acknowledged that the priority of the cardiac lesion is merely a hypothesis resting on the absence of proof of the contrary time relation.

The first patient lived at least three years with a double aortic lesion; during most of this time she was doing housework, and she made a good recovery from a moderately severe gynecological operation. Her tricuspid regurgitation was a late development. It seems that life was prolonged to the extent that vitality and medication could withstand adverse circumstances. The second patient died unexpectedly; his murmur was only a mitral regurgitant, apparently quite well compensated for. The enormous dilatation of the right auricle can scarcely be regarded as directly due to the mitral lesion, since the intermediate valves were intact. I am inclined to think that the long-continued lung trouble was the direct cause of the auricular dilatation, and that the latter was the real cause of death. Clinicians throw little light on auricular disease. H. C. Wood states that when digitalis is theoretically indicated it sometimes fails to do good, or actually increases the bad symptoms on account of increasing the strain on a dilated auricle. In the case cited, heart tonics were not much used, simply because they did not seem to be indicated. The post-mortem explanation of the vague precordial pains and of the prostration of a man apparently fairly strong and well nourished is an interesting lesson, yet it affords little information as to the conduct of another similar case.

An elaborate discussion of the relation of the various lesions found in these two autopsies to the cardiac disease would be a more than twice-told tale, yet I wish to allude briefly to this point. In both patients there was pulmonary congestion with almost inevitable catarrh and, as death approached, œdema. In both, the left lung was firmly adherent, the right lung relatively free; and in both the free lung was the more œdematous. The broncho-pneumonia of the male patient, although predisposed to by the con-

gestion of heart disease, seems to have been due largely to exposure to cold.

In both cases are noted the effects of venous engorgement of the kidneys. In the male patient the irritation of the venous blood had just begun to cause interstitial growth. In the female the tearing off of renal parenchyma with the capsule shows a more marked interstitial inflammation. To call the lesion *diffuse nephritis* is simply a recognition of the fact that it is scarcely possible to find a chronic diseased process which involves one histological part of an organ without affecting contiguous tissues.

Both spleens were small. According to the dictum of the late Henry F. Formad, we can never have intestinal disease without a marked increase in the size of the spleen. In the present cases the intestines showed no lesions except that in one the colon seemed smaller than usual, even after allowing for post-mortem contraction. This would be readily explainable as an atrophy from comparative disuse. The old perisplenitis and the possible infarction are common lesions—so common that they seem to have comparatively little clinical significance.

The livers, like the kidneys, show different stages of the same process. In the male was found a chronically congested or nutmeg liver, somewhat large, with no interstitial change demonstrable macroscopically, with fatty infiltration just beginning. In the case of longer duration the nutmeg appearance was still noticed, but the organ was plainly cirrhotic, the interstitial tissue had contracted so as to reduce the liver to two thirds of its normal size, and persistent suboxidation was evinced by the well-marked fatty infiltration which so generally accompanies cirrhosis.

In the stomach of the male patient moderate catarrh was expected; but, if present, it was not sufficient to be distinguished from the gray, slimy appearance of a normal stomach examined several hours after death. In the other case chronic gastritis, which so frequently results from the backing up of venous blood, was conspicuous. With it was found a moderate degree of dilatation not due to mechanical obstruction, but to atony of the organ.

In neither case was there marked dropsy; one patient dying too early, the other escaping it largely on account of rest and medication.

174 FRANKLIN STREET.

THE THERAPEUTICS AND TREATMENT OF THE URIC-ACID DIATHESIS.

By J. LINDSAY PORTEOUS, M. D., F. R. C. S. Ed.,

TONKERS, N. Y.

SOME authorities state that there are no recognized symptoms of a definite kind to warrant the term "uric-acid diathesis," but this I venture to question. I will begin my remarks on this subject by the unusual course of prefacing them with the symptoms of two cases recently under my observation, and I hope to be able, in part at least, to prove that my right to question the above assertion is not wide of the mark.

CASE I.—E. F., girl, aged ten years, thin and neurotic, complains daily of frontal headache, frequent pain in region of kid-

neys, also of bladder. Restless at night, often grinds her teeth, has a small appetite and is very particular about her food, and the food she prefers is of very poor nutritive quality. She is often very bright and happy, but as often dull and depressed. She easily "takes cold," and frequently has a chill, which generally precedes the symptoms above mentioned. She has a deep, hollow cough; her eyelids are at times cedematous and feet cold; has also chronic enlargement of the tonsils; very little exertion causes profuse perspiration. She is also persistently constipated. The family history reveals gout for several generations on the paternal side. An examination of the urine during these attacks shows a high specific gravity; there is an excessive acid reaction, with sometimes a trace only of albumin; at other times a considerable amount. The microscope revealed uric-acid crystals in quantity. During the attacks there was a frequent desire to micturate, and this probably is attributable to the irritation caused by the uric acid. The faces were generally of a very dark color.

CASE II.—A typical case of a man aged thirty-five years; general appearance plethoric; subject to flushings and severe congestive headaches, described as a "fullness in head and like to burst." At other times the headache is like hemieric neuralgia. There is a dark, almost black shade beneath the eyes, and sometimes on inner half of upper eyelids and side of upper part of nose. There is slight "bagginess" beneath the eyes, and the skin there is easily pinched up, which distinguishes it from Bright's disease in this particular point. The appetite always good, but frequently discomfort in the epigastric region after food. Considerable flatulence, causing sharp pain in cardiac region. Constipation; faces dark in color; dull, aching pain in lumbar region, sometimes also in bladder. A frequent desire to micturate. Urine sometimes clear, sometimes dark and muddy. A feeling of lassitude and drowsiness relieved by active exercise. Such are the symptoms in a child and in an adult having the uric-acid diathesis.

Let us now, in brief, consider what uric acid is. It is a bibasic salt—that is, it contains two atoms of a replaceable hydrogen. The formula for it is $H_2(C_2H_2N_4O_3)$, or, more simply, H_2u . It forms three regular orders of salts—namely, neutral urates (formula M_2u), and urates or bi-urates with the formula of MHu , and quadri-urates. The neutral urates have lately been by some authorities brought prominently forward as the cause of gout. Sir William Roberts has, however, in a recent able article, disproved this theory in the following practical manner: He says: "The neutral urates can only be produced in the presence of caustic alkalies and in the absence of carbonic acid and the carbonates. But caustic alkalies can not exist in the living organism, and carbonic acid and the carbonates are everywhere present. It would therefore seem impossible that the neutral urates should ever play any part in the physiological or pathological history of uric acid, and until it can be demonstrated that the salts do actually exist in the body, or at least that they can be formed under conditions which are known to be possible in the living body, it is futile to frame theories in which these compounds are made to intervene. With these remarks the neutral urates may be absolutely dismissed from our consideration as having neither part nor lot in the vital history of uric acid, whether in health or in disease." Such remarks from such an eminent authority may be considered conclusive. Although bi-urates are known pathologically as constituents of gouty

concretions, yet they are not known with certainty as physiological constituents either of the blood or urine. On the other hand, the quadri-urates are known to exist in human urine and that of birds and serpents. Roberts has proved that uric acid enters into solution in the first instance, not as neutral urates or as bi-urates, but as quadri-urates. In the healthy and those not victims to the uric-acid diathesis, the normal combination of uric acid with alkaline bases maintains its integrity for some time after micturition, as well as when passing through the usual channels. If, from some cause or other, decomposition takes place in the kidney or in the bladder, the uric acid is set free and deposited in the crystalline form; hence the well-known symptoms of gravel. We must not forget, however, that all acid urines, if guarded against septic influences, deposit uric acid sooner or later. We may ask what prevents the breaking up of the quadri-urates and the deposition of uric-acid crystals within the kidney and bladder? The same authority whom I have already quoted has recently made elaborate experiments on this subject. He concludes that there are certain inhibitory ingredients in the urine which prevent the breaking up of the quadri-urates; that this inhibitory power resided partly in the crystalloids of the urine; that the chief crystalloids are urea, the chlorides, phosphates, and sulphates of potassium, sodium, ammonium, calcium, and magnesium. Of these, he found that urea had no power to delay decomposition of the quadri-urates. The chlorides and sulphates, in the proportion of one per cent. and upward, had considerable power. The potassium salts, however, had more effect in preventing the decomposition than salts of ammonium and sodium; but none of them approached the natural urine in its power of postponing the decomposition of the amorphous urate. He found that dipotassic phosphate, in a 0.2-per-cent. solution, acted almost as slowly on the deposit as natural normal urine.

The pigments or coloring matters of urine undoubtedly have great inhibitory power. Urine that had been filtered through animal charcoal and so deprived of its coloring matter acted more quickly on the amorphous urate than the same urine before it was filtered.

Alkaline urine can never be the cause of gravel, nor can it cause the uncomfortable irritation of the urinary channels felt in the patient suffering from the uric-acid diathesis. We may also assert that a diminution of salines and pigments in the urine favors the precipitation of uric acid.

Seeing that in certain unhealthy conditions of the human body there is a decided tendency to precipitation of uric acid, it is of great importance to find out, as far as possible, some of the causes of the abnormal condition. We know that the children of the poor suffer far more in proportion than those of the better off from stone and uric acid. Their mode of living impoverishes the urine of its saline matters. They are fed principally on bread, gruel, and potatoes. These contain little mineral matter. They have only a small quantity of milk, meat, and fish. Now, we know that wheat flour only contains 0.51 per cent. of mineral matter, whereas meat and fish contain 5 to 5.50 per cent. of mineral matter in proportion to the totality of the dry substance. The same may be said to be the cause of so

many cases of stone found among the natives of India, who live chiefly on rice. It has been shown that sailors, from the amount of salt provisions they use, are singularly free from calculus. On the other hand, we find men in easy or luxurious circumstances suffering from the uric-acid diathesis. In their urine there is no want of either pigments or salts; still they suffer, often severely. This can only be accounted for by their having an excessive quantity of uric acid secreted. The quantity in the urine bears no constant relation to the rate of its excretion by the kidneys. The degree of acidity of the urine must exercise a power over the time of precipitation. The more acid, the quicker the precipitation. Knowing this, our object must be to render the urine less acid as quickly as possible. In prescribing a line of treatment, it is, according to Roberts and Garrod, very essential to differentiate between the gouty and uric-acid diatheses. Although many authors consider these complaints identical, such is undoubtedly not the case. We may find gout alternating with gravel in the same individual; but this does not by any means prove that they are the same disease. Uric acid appears in both diseases, but in different circumstances. In gout the trouble originates in the blood and tissues, and, according to Roberts, is deposited in a state of combination as a bi-urate. In gravel it occurs in the kidney, and is deposited in the urine in a free state. This is very necessary to know, as it may guide us in determining our line of treatment.

As we have already stated, we must endeavor in treating this disease to render the urine less acid as early as possible. I have also stated that it is impossible for an alkaline urine to deposit uric acid, or for a neutral or slightly acid urine to deposit it. In citrate of potassium we have a powerful agent to render the urine less acid, and, with the addition of benzoate of lithium, I have found in many cases that in from twenty-four to forty-eight hours I had neutralized the urine. But we know that gravel may last intermittently for months or even years, and we could hardly expect a patient to persist for weeks or months in taking alkaline doses. We must direct our attention to some other means, and those means must, as far as possible, be preventive, using the alkalies only on occasions where some error in diet, or some other cause, has increased the amount of uric acid.

Precipitation of uric acid may take place either in the kidneys or bladder. The results of the former are more serious than those of the latter, as any deposit in the bladder is washed out during micturition. We ask, How are we to distinguish between the condition of the urine as it is secreted by the kidney and the urine after it has been some time in the bladder? This is very important to know. Urine which has been in the bladder for some hours may, according to Roberts, have frequent changes from acid to alkaline, from dilute to concentrated, from richness to poverty of uric acid. To get, therefore, a correct knowledge of the urine as it passes through the kidneys the urine must be obtained and examined at short intervals. Roberts made some valuable experiments with the object of finding out a preventive treatment of urinary gravel. The following are his conclusions: That the char-

acter of the urine was most affected (1) by the digestion of food, (2) by prolonged fasting, (3) and by sleep. He found that *after* a meal, no matter of what it consisted, the acidity decreased and the amount of urine increased. Prolonged fasting, on the other hand, raised the acidity and diminished the flow of urine. During sleep, which was likewise a time of abstinence, acidity reached its maximum, and the flow of urine its minimum. The percentage of uric acid was greatest during the time of sleep, but the hourly secretion was greatest after meals. From what has been previously said, we know that the greatest risk of renal precipitation is during sleep, especially toward breakfast time.

We have seen from the foregoing that the acidity is most dangerously increased during sleep. To lessen the danger we must give some drug that will have the effect of counteracting the acidity. In my experience, I have found that a dose at bedtime, consisting of ten grains of benzoate of lithium and thirty or forty grains of citrate of potassium in half a glassful of water acts admirably. If, however, the acidity is very great, Nature steps in and makes the sleeper restless and finally awakens him. This means that the alkalinity has again been overcome by the acidity, and another dose is necessary. Although, as we have already seen from Roberts's experiments, the urine is less acid during the day when digestion is going on, it may be necessary to give one or two doses—the same as already mentioned—during the day. If, however, for some reason this dose can not be taken as often as might be necessary, the meals ought to be increased in frequency.

In the nocturnal enuresis of children I have found this to work admirably—viz., potash and benzoate of lithium during the day, and always something to eat at bedtime. No doubt many such cases are caused by uric acid irritating the bladder and kidneys. Our object in treating patients who have uric-acid diathesis is not so much to entirely prevent precipitation as to retard it till it reaches the bladder, when we know it will be washed out as a rule. I say as a rule, because there are those who suffer from atony of the bladder, either from chronic cystitis or paralysis, or who have enlarged prostate and can not entirely empty the bladder. To such patients I would not only prescribe daily and nightly doses of the alkalies mentioned, but also that the catheter be used frequently, and the bladder washed out from time to time with a weak solution of soda.

Fortunately, it is extremely rare for any patient to be troubled all the time with a tendency to precipitate uric acid. Therefore I would advise those who have suffered from it to curb their appetite, lessen the quantity of nitrogenous food taken, and use freely farinaceous substances, with salads, fruits, and garden vegetables. The subject of diet is a very difficult one, as some authorities say, "Avoid fruit, sugar, and fat"; others order fat in abundance and no starchy articles of diet. Roberts states that the most reliable investigations prove that sugar, fat, and starchy matters have no influence on the production or secretion of uric acid. The only point of real value made out by accurate investigation is that the excretion of uric acid is diminished by lessening the albuminoid ingredients of food, and increased by the reverse.

I conclude from the foregoing remarks that the principal efforts of the physician, when he has a patient suffering from uric-acid diathesis, must be to guard against renal precipitation of uric acid. If the means suggested in this paper for that purpose be intelligently carried out, the risk of attacks of gravel and even vesical calculi may be reduced to a minimum.

80 WARBURTON AVENUE.

REPORT OF A CASE OF OBSTETRICS.

By JOHN FRANCIS BURNS, M. D.,

ATTENDING SURGEON TO ST. JOHN'S HOSPITAL,
LONG ISLAND CITY, N. Y.

I was called to Mrs. W., aged twenty-eight, in labor with her fourth child, her three previous children having been extracted with forceps after tedious labors. Two had died as the result of forceps operations immediately after birth, and one subsequently, charged to the "result of operation."

Physicians in attendance at previous labors had attributed the dystocia to a contraction of the pelvic bones. I examined the patient and found a roomy pelvis, with os uteri one quarter dilated, but situated very far back and high up. The patient states that her womb is "always prominent," and that the liquor amnii has been scanty in previous labors. Examination confirms this, as there is marked anterior obliquity of the uterus. I expressed the opinion that there seemed no good reason why she should not be delivered of a child without the forceps, as the womb could be easily replaced, and after replacing and confining it I left subject to call, the pains then occurring at twenty-minute intervals.

I had hardly left the house when the pains markedly increased in frequency and force, and inside of a half hour she was delivered of a female child weighing nine pounds and four ounces, and whose cranial measurements exceeded the normal in all diameters. I reached the patient in time to assist in the expulsion of the placenta. The mother made a normal convalescence and the child remains healthy and strong.

The foregoing is but a leaf from the diary of a physician, and at first sight presents nothing of importance, but it serves to illustrate a very common error in obstetrics. It is certainly more than a coincidence that a woman should have to be delivered three times with the forceps and then have an almost spontaneous delivery of a very large child, especially after the correction of anterior obliquity. I can hardly entertain the idea of the influence of suggestion in connection with the result, although I am not unmindful of the influence exerted on the minds of patients in labor by these means.

It can readily be conceived upon scientific grounds why a complication of this character should render labor so difficult and result so fatally to the children. In the first place, the extreme tenuity of the abdominal wall prevents the auxiliary assistance usually obtained from this source, and the obliquity throws the force of the uterine contractions upon a portion of the child's body not in the axis of the pelvic canal. The relaxation of the ligaments also prevents the presenting part from engaging in the pelvis, and if the condition go unrecognized, the application of the forceps only increases the danger to the mother and child, as there must of necessity exist an acute angle at some part

of the child's body upon which excessive traction must be made. Again, it can readily be understood how such a condition would induce malposition in the presenting part. The prominence given in text-books (and even in more advanced works on obstetrics) to pelvic contraction as a cause of dystocia is no doubt largely responsible for the overlooking of the many other abnormalities that may cause it.

This case, to my mind, illustrates the necessity of a physician keeping in mind that there are two ends to the parturient canal, and the physician who keeps this in mind will have to apply the forceps much less frequently than he who only considers the bony outlet.

If this case is more than a coincidence it certainly proves that the error is a common one, for three physicians have successively failed in this one case. If the history of this case awakens interest in even one practitioner's mind to the importance of obliquities of the uterus as a common cause of dystocia, the object of the writer will have been attained.

A REPORT OF MY OWN CASE OF
DOUBLE TALIPES VARO-EQUINUS
OF THE SECOND DEGREE,
OPERATED ON BY PHELPS'S METHOD.*

By J. H. HUNTLEY, M. D.,
ALGER, OHIO.

I WAS born on April 11, 1851, with double talipes equinovarus. At the time of my birth I had an older half-sister with a similar deformity. We were both children of the same father, but not of the same mother. Notwithstanding that both cases were congenital, there was no hereditary cause in the family history on either side.

Nothing was done to correct the deformity in my case until I was in my sixteenth year, when I undertook to have an operation on my own responsibility. Dr. M. did the operation in May, 1867, by dividing, subcutaneously, the tendo Achillis, the plantar fascia, the tibialis anticus, and the tibialis posticus. He manipulated the feet and made an effort to put on a straight shoe with brass soles and steel side-braces running above the knee. This treatment was both very painful and inefficient. After I had worn them for about a month an aneurysm formed on the left foot in the posterior tibial artery. An operation was done by the same surgeon to relieve the enlargement by ligating the artery above the aneurysm. In about seven days secondary hæmorrhage set in, and I came near bleeding to death. Another operation was now done higher up by cutting down on an artery which was not found. I was placed on my back and my foot swung up at an angle of forty-five degrees, and kept in this position for twelve days until all danger of hæmorrhage was past.

I did not move with my feet until the next spring. I then went to an orthopaedic institution in Charleston, Ill., under the charge of Dr. H. R. Allen. I was there operated on by subcutaneous tenotomy of the same tendons as before and his clubfoot shoe put on, which is a modification of the Sayre shoe. I wore these shoes three years, and then returned to the same man at Indianapolis, Ind., and had the tendo Achillis divided again and a new pair of braces applied. I wore these for about two years, and then quit wearing a brace on the right foot, but kept it on the left. In my right foot I still had a tense plantar fascia and

tendo Achillis, and could not walk barefooted or get my heel down, but had to pad it up with cotton. In the winter of 1876-'77 I was at the Michigan University attending medical lectures, and Professor McLean thought the Sayre rubber-muscle method would help me. He applied the rubber tubing on the outer side of the leg to take the place of the peronei muscles, and also applied the interrupted current of electricity to the atrophied muscles. This was continued for three or four months without any benefit. I then gave up the idea of ever having anything more done. But in the mean time I consulted several good surgeons; among them was Professor Gunn, of Chicago. They all told me to let them alone.

In 1890 I read an article on Phelps's method by Dr. A. M. Phelps, of New York. I was well pleased with the method, and resolved to see him and make another trial, as I was getting worse as I grew older. I felt determined to have an operation by the open-incision method or have a Pirogoff amputation on the left foot.

I went to the Post-graduate Hospital and was operated on February 24, 1892. Fig. 1 represents the condition of my feet at that time.

Dr. Phelps did his ordinary operation for talipes equinovarus without doing any bone operation. The left foot required a lever force of nearly fifteen hundred pounds to bring the foot into position and bring the heel down. In ten weeks I was able to assume my duties as a physician, and there has been no tendency to relapse, but a steady improvement during the ten months that have elapsed since the operation. I stand well on the bottom of my feet and perform my labor with more comfort by one half than I ever dared to hope. Fig. 2 is from a recent photograph.

FIG. 2.

RHEUMATISM

AS A CAUSE OF PARTIAL DEAFNESS, WITH TINNITUS.

By J. H. VADAKIN, Ph. G., M. D.,
BETHANY, ILL.

HAVING recently read with pleasure an article in your valuable journal on The Rheumatic Throat, I thought it might be of interest to some of our profession to read a report of a case which recently came under my observation and treatment:

A widow, Mrs. W., aged about thirty-five years, the mother of one child aged fourteen years, came to me for treatment for rheumatism, stating also that she had been hard of hearing for

* Read before the Section in Surgery of the New York Academy of Medicine, May, 1892.

a number of years. She had just recently come here from England, where she had been treated for her ear trouble without any relief. When I was called to see her she had just been brought there to her sister's house from a city a distance of about one hundred miles away, where she was employed as head cook in a large family. She was terribly emaciated, suffering the most excruciating pain, total anorexia, and, to say the least, she was in a most deplorable condition. She said her father and mother were both rheumatic, and that she supposed she had inherited her trouble from them. The rheumatism had troubled her very little. When she noticed the ear trouble she consulted a physician for tinnitus before she did for rheumatism. On physical examination, heart and lungs were found normal, bowels constipated, joints all puffed and tender. I put her on the following treatment. She improved very rapidly; in fact, after the first two doses she said her pain was entirely gone. She began to eat. She had been vomiting everything she ate or drank; this stopped immediately. She went right on and made a rapid and uneventful recovery.

R Sodii salicylat. ʒ ij;

Aquæ dest. q. s. ad ʒiv.

M. Ft. sol. Sig.: Teaspoonful every four hours until easy, then reduce gradually.

R Tr. ferri chl. ʒ ij;

Syr. limonis. ʒ ij.

M. Sig.: Teaspoonful every four hours until easy, then reduce gradually.

R Fl. ext. cascara sag. ʒ ij;

Elix. simplicis. ʒ ij.

M. Sig.: Teaspoonful as often as needed to move bowels regularly.

R Hydrogen peroxide. ʒ j;

Listerine. ʒ j;

Aquæ rose. ʒ iv.

M. Sig.: Use with syringe in ears three times a day.

In examining the ears, I found the external auditory meatus filled with a dark, thick, tar-like substance, which I cleaned out with absorbent cotton wound on the end of an applicator, and then used the above wash. She returned to her place in about six weeks and has remained well ever since. This is about eighteen months after she began treatment. She continued the treatment about four months. Since treating the above case I have recently treated her daughter and an older sister for rheumatism, with good results in both cases. The urine in all three cases was loaded with uric acid, showing its presence both microscopically and chemically.

The late Professor Peter, of Paris, who died last month at the age of sixty-nine years, was a striking example of the few men who achieve success and renown in the face of unusual difficulties. It appears from a memoir of him written by M. Jules Rochard, published in the *Union médicale* for June 13th, that his early career was that of a typesetter, that he was thirty-five years old when he obtained his medical degree, and that it was not until twenty years later that he became a professor.

The Medical Society of the County of Otsego, N. Y., will hold its annual meeting at the Court House in Cooperstown on Tuesday, the 18th inst. The programme includes the following papers: Typhoid Fever, by Dr. E. E. Dye (the discussion to be opened by Dr. P. K. Strong); The Management of the More Common Diseases of the Eye, by Dr. A. H. Brownell; and Cholelithiasis, by Dr. L. H. Quackenbush (the discussion to be opened by Dr. J. H. Moon).

The Death of Dr. James J. Levick, of Philadelphia, is announced in the *Medical News* as having taken place on June 25th. The deceased was sixty-eight years old.

NEW YORK, SATURDAY, JULY 15, 1893.

THE DECLINE OF SCARLET FEVER.

THE medical profession on each side of the Atlantic has been interested to observe a diminished mortality and sickness-rate of scarlet fever. Our English brethren are already engaged in inquiries as to the causes of this decline. The *Medical Press and Circular* for April 26th takes up the subject by comparing the mortality in England in 1881, when 14,275 deaths from that disease were registered, with that for 1891, when 4,956 was the total. The Registrar General's Report for 1891 pointed out the fact that the scarlatinal mortality had not reached so low an ebb since the laws of registration went into operation. This is true not only when taken proportionally to the population of the country, but absolutely. During the seven years ending in 1891 the deaths never reached 8,000 in any one year, and the average annual total was only 6,458, while in no previous year, except 1884, had there been fewer than 11,000 deaths from this cause. Dr. William Ogle, the medical head of the General Registration Office, has been greatly impressed by watching "this large and long-sustained diminution in the mortality from scarlet fever as one of the most curious facts in our death statistics, and as yet without adequate explanation."

According to Dr. Ogle, there are three probable influences that have contributed toward the result, but neither he nor the readers of his report can accept them as sufficient causes. In the first place, he finds that the birth-rate of England shows a material decline in the last decade, in consequence of which the proportion of children to the population—that is, the proportion of individuals most liable to suffer from scarlet fever—had undergone a marked reduction; but this can be numerically estimated on the bases of high and low birth-rates, and it will be found that a reduction of seven per cent. only in deaths by scarlet fever can thus be accounted for.

In the second place, there has been a number of sanitary undertakings at work in the direction of a reduced scarlet-fever mortality, not the least of which has been a growing enforcement of isolation of the sick in the infectious-disease hospitals. For example, in and about London, more than half the deaths from this cause now take place within the wards of the fever hospitals, whereas in 1878 not more than seven per cent. of such deaths occurred in hospitals.

Thirdly, the scarlet fever of to-day is of a milder type than that of ten years ago. The evidence to corroborate this view is obtainable from the Registrar's statistics in the fever hospitals; from 1874 to 1878 the average mortality in every hundred patients in those hospitals was 12·88, while in the years from 1887 to 1891 it was 8·56. This harmonizes with the gen-

erally expressed experience of the profession that there is a diminished virulence in scarlet fever. This renders plausible the proposition of those who believe that scarlet fever has been passing through a modification of type, but just how it is caused and how much further it may be expected to extend remain to be explained. Whether the disease has reached the end of its tether, as was the case with leprosy in England and France in the fifteenth century, or is simply acting in alternation with epidemic influenza, as some think, is a question not easy to solve in our present knowledge of epidemiology. Dr. Ogle's opinion is that epidemics of scarlet fever will not soon, if ever, again be the scourge to infant life that they have been. This hopeful view is based on the knowledge that he has, as an official, that the public-health laws have been administered with a growing efficiency, and that the best results are now being felt from processes of sanitation, such as drainage, water-supply, and the like, that require years for their building up and years for their full fruition. In proof that sanitation is at work in this beneficent way, there is adduced the fact that the mortality from typhoid fever is, almost year by year, showing great reduction. The lowest death-rate from that cause ever shown for England was that of 1891, and the same seems to be the case with reference to typhus fever and simple (or non-defined) fever, during the same period.

A CONGRESS OF NONOGENARIANS AT PARIS.

THE editorial staff of *La Science médicale* has undertaken to convene, for scientific purposes, a considerable number of aged persons. No distinction as to nationality will be made in regard to old people who are provided with documents proving that they have passed the age of ninety years. Expenses of traveling and lodging at good hotels are to be defrayed by the medical committee in charge of the affair, and the well-being of the delegates will be cared for during their stay at the congress. Three gold medals will be awarded, one to the oldest, one to the strongest, and one to the most intellectual. Although there are supposed to be not fewer than two hundred centenarians in France, the presence of a few only of them may be expected; by far the greatest number of them reside in the departments that skirt the Pyrenees. It is supposed that the congress will have for its president Dr. De Boissy, who practiced medicine at Havre for seventy years. He was born in April, 1793. Dr. De Boissy is still vigorous, and not long since read a scientific paper before a public meeting. The convention will be called to order on July 25th at the Palais des arts libéraux.

MINOR PARAGRAPHS.

"LABORATORY CHOLERA."

A CASE of prompt identification of cholera by bacteriological tests has been reported in a recent number of the *Deutsche medizinische Wochenschrift*. It was a case of what the Germans call *Laboratoriumscholera*—that is, one of accidental infection occurring in an assistant in a pathological laboratory. The reporters are Dr. Freymath and Dr. Lickfett. They were

enabled to arrive at a bacteriological diagnosis of the case in about six hours after the symptoms caused them to suspect that choleric infection had taken place. The patient, a laboratory attendant, aged twenty years, fell sick with diarrhoea and pains in the abdomen on April 11th. A little later, rice-water discharges were reported. On inquiry, it was found that, on the 7th or 8th, the man had perhaps undergone exposure to infection by cholera at the laboratory. On the 12th the comma bacilli were found to be numerous; there were spirillum forms, s-forms, cocci, and straight bacilli. Cultivation of the bacilli was practiced in a nutrient medium, and colonies were obtained showing the characteristics of the comma variety. Cover-glass preparations of these growths were fixed and stained with Ehrlich's gentian-violet, and were seen to consist of the comma bacillus solely. This confirmation was obtained in six hours and a half after the infection had been suspected. The further growth of the colonies and the behavior of stab-cultures were confirmatory of the diagnosis of cholera. The patient's stools were examined daily for two weeks and over, but there were no colonies observed after the 16th. The promptness of the bacteriological measures adopted enabled the physicians to report their case to the authorities without delay, and this in turn led to speedy official disinfection and isolation.

FORMANILIDE.

THE *Medical Week* for June 30th gives a brief account of this substance, that bears the same relationship to formic acid that acetanilide does to acetic acid. It is possessed of analgesic and antipyretic properties analogous to those of antipyrine and acetanilide. In doses of from ten to fifty centigrammes (a grain and a half to seven grains and a half) in twenty-four hours it reduces the temperature in pyrexia and relieves all pain of a neuralgic character; the antipyretic action is manifested at the end of five minutes, the maximum effect being produced in three or four hours. It may be attended by cyanosis, but never by any symptoms of collapse. It is a valuable local anæsthetic, the powdered substance, or a five-per-cent. solution, producing marked local anæmia followed by complete insensibility lasting from two to sixteen hours. A one per-cent. solution of formanilide, injected into the alimentary canal of a rabbit, suspends peristaltic action for a variable period of time, and, injected into the bladder, it causes cystic paresis. As an anæsthetic it is not so powerful or rapid in its action as cocaine, but the effect is more persistent. Formanilide, applied to a bleeding surface, arrests hæmorrhage more rapidly than antipyrine does.

THE CINCINNATI COLLEGE OF MEDICINE AND SURGERY.

THE chair of the principles and practice of medicine in this school has been tendered to Dr. J. C. Culbertson, the retiring editor of the *Journal of the American Medical Association*. Dr. Culbertson has returned to the editorial chair of the *Lancet and Clinic*, after an absence of two years at Chicago.

TROPACOCAINE IN OPHTHALMIC PRACTICE.

In the *British Medical Journal* for June 24th Dr. G. Ferdinands publishes the results of his clinical observations on tropacocaine in ophthalmic practice. He finds that it is more reliable in its action than cocaine, the anæsthesia it produces lasting a little longer and also being produced in inflamed tissue. There is a complete absence of that haze over the cornea that is so characteristic of cocaine anæsthesia. For general use a two-per-cent. or three-per-cent. solution is sufficient, and a five-per-

cent. solution may be used with safety when anesthesia of the deep-seated parts of the eye is required. The solutions made with distilled water keep well and retain their strength for months; and in only one case, in which a ten-per-cent. solution was used, did any disagreeable symptoms occur. It practically has no mydriatic action and it is not a hæmostatic.

THE FREAKS OF HEREDITY.

At a recent meeting of the Paris Hospital Medical Society, according to a report published in the *Union médicale* for June 13th, M. Marie showed the photograph of a woman with a supplementary mamma, and stated that nearly all the members of her family, for four generations back, had presented the same anomaly. Moreover, among her father's fifteen brothers and sisters there had been six twins, and among her own brothers and sisters, twelve in number, eight twins. All these fourteen twins were of the male sex, showing that the tendency to beget twins could be transmitted through the male line. Another example of this possibility was cited by M. Le Gendre—that of the Scotch poet, Burns, who was alleged to have become the father of twins four times, twice by his wife and twice by his mistress.

A MEDICAL BISHOP.

A DISTRICT of southeastern Africa, called Lebombo, has been apportioned to become a new diocese, and the Rev. William E. Smyth, M. D., has been appointed by the Anglican church authorities to the bishopric.

ITEMS, ETC.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending July 11, 1893:

DISEASES.	Week ending July 4		Week ending July 11.	
	Cases.	Deaths.	Cases.	Deaths.
Typhus	0	1	7	1
Typhoid fever.....	17	5	16	5
Scarlet fever.....	74	9	75	9
Cerebro-spinal meningitis....	7	6	6	7
Measles	159	17	204	13
Diphtheria.....	125	45	130	43
Small-pox.....	6	1	3	0

The Legion of Honor.—The *Union médicale* announces that Dr. Kaposi, of Vienna, has been made an officer, and Dr. Riehl, of the same city, a chevalier.

Changes of Address.—Dr. James E. Newcomb, to No. 118 West Sixty-ninth Street; Dr. Frank Parsons Norbury, to the Hoffman Building, Jacksonville, Ill.; Dr. Alexander Rixa, to No. 337 East One Hundred and Sixteenth Street.

Naval Intelligence.—Official List of Changes in the Medical Corps of the United States Navy for the week ending July 8, 1893:

LEYS, JAMES S. Commissioned an Assistant Surgeon in the Navy.
 BEARDSLEY, G. S., Medical Director. Detached from the Navy Yard, Washington, D. C.
 WHITE, C. H., Medical Inspector. Detached from the Smithsonian Institution.
 WISE, JOHN C., Surgeon. Ordered to the Navy Yard, Washington, D. C.
 GRAYVATT, C. U., Surgeon. Ordered to the Smithsonian Institution.
 BROWNELL, C. De W., Assistant Surgeon. Detached from the U. S. Steamer Newark and granted one month's sick leave.

EVANS, S. G., Assistant Surgeon. Ordered to the U. S. Receiving-ship St. Louis.

RUSH, C. W., Passed Assistant Surgeon. Ordered before the Retiring Board.

Answers to Correspondents:

No. 409.—The Medical Society of the State of New York is the older body. Its annual meetings are held in Albany, in February. The New York State Medical Association meets in the autumn, usually in New York.

Book Notices.

The Mediterranean Shores of America. Southern California: its Climatic, Physical, and Meteorological Conditions. By P. O. REMONDINO, M. D., Member of the American Medical Association, etc. Fully illustrated. Philadelphia and London: The F. A. Davis Co., 1892. Pp. xiv to 160.

THE author maintains that various diseases, and pulmonary affections in particular, are the direct products of extreme variability of weather. He proves by statistical tables that pneumonia and pulmonary tuberculosis are almost unknown to the natives of Southern California, because of the various climatological, physical, and other conditions which determine an evenness of temperature and a hygroscopic state that are conducive to comfort and health. He criticises physicians for sending their consumptives to great altitudes, and cites numerous cases of cure of pulmonary tuberculosis by merely residing in southern California. The temperature rarely reaches there below 20° F. in the winter months, and is generally about 80° F. in the hottest summer months; if by exception it does reach 100° F. it is never as oppressive as this temperature is known to be in New York, and the inhabitants, the author says, would hardly feel uncomfortable if it were not for the mere knowledge of the height of the temperature. In the winter it is never necessary to heat apartments artificially. The author has lived there for twenty years, and never had artificial heat in his house. The book is handsomely got up and well illustrated, and it is not too much to say that it is fascinating reading.

Diseases of the Eye. A Practical Treatise for Students of Ophthalmology. By GEORGE A. BERRY, M. B., F. R. C. S. Edin., Ophthalmic Surgeon, Edinburgh Royal Infirmary, etc. Second Edition, revised and enlarged. With Colored Illustrations from Original Drawings. Philadelphia: Lea Brothers & Co., 1893. Pp. xxii-727.

EVERY one who has become accustomed to consult the first edition of this work will gladly seize the opportunity to discover what improvements the author has made in it. It has been largely rewritten, the arrangement of the chapters has been greatly changed, and many new drawings and diagrams have been introduced. Most, if not all, of these changes are improvements, though a change in arrangement may not appeal as such to the student or practitioner who has become used to opening the book at about a certain point in search of particular information, and now finds himself obliged to consult the index. But the very high standard of the work as a clinical text-book has been maintained, and the work is to be commended in the highest terms.

BOOKS, ETC., RECEIVED.

A Text-book of Medicine, for Students and Practitioners. By Dr. Adolph Strümpell, Professor and Director of the Medical Clinique at Erlangen. Second American Edition. Trans-

lated, by permission, from the Second and Third, and thoroughly revised from the Sixth German Edition. By Herman F. Vickery, A. B., M. D., Instructor in Clinical Medicine, Harvard University; Physician to Out-patients, Massachusetts General Hospital, etc.; and Philip Coombs Knapp, A. M., M. D., Clinical Instructor in Diseases of the Nervous System, Harvard University; Physician to Out-patients with Diseases of the Nervous System, Boston City Hospital, etc. With Editorial Notes by Frederick O. Shattuck, A. M., M. D., Jackson Professor of Clinical Medicine, Harvard University; Visiting Physician to the Massachusetts General Hospital, etc. With One Hundred and Nineteen Illustrations. New York: D. Appleton & Co., 1893. Pp. xxiii-1043.

Recent Developments in Massage, Historical, Physiological, Medical, and Surgical. By Douglas Graham, M. D., Boston, Mass. Second Edition. Illustrated. Detroit: George S. Davis. 1893. Pp. iv-128. [*The Physicians' Leisure Library.*]

Manuel du médecin praticien. La pratique dermatologique et syphiligraphique des hôpitaux de Paris. Aide-mémoire et formulaire. Par le Professeur Paul Lefert. Paris: J. B. Baillière et fils. 1893. Pp. vi-7 to 288.

On Snake Poison. Its Action and its Antidote. By A. Mueller, M. D. Sydney: L. Bruck. 1893. Pp. vi-85.

Eighteenth Annual Report of the Secretary of the State Board of Health of the State of Michigan, for the Year ending June 30, 1890.

Miscellany.

The New Medical Law of Pennsylvania.—The Medical Society of the State of Pennsylvania's committee on legislation, consisting of Dr. H. G. McCormick (chairman), Dr. W. Murray Weidman, Dr. J. W. Moore, Dr. I. C. Gable, Dr. C. L. Stevens, Dr. W. S. Foster, and Dr. John B. Roberts (secretary), is to be congratulated on having secured the passage of a satisfactory medical law for the State. The following is the text of the law:

An Act to establish a Medical Council and three State Boards of Medical Examiners, to define the powers and duties of said Medical Council and said State Boards of Medical Examiners, to provide for the examination and licensing of practitioners of medicine and surgery, to further regulate the practice of medicine and surgery, and to make an appropriation for the Medical Council.

Whereas, The safety of the public is endangered by incompetent physicians and surgeons, and due regard for public health and the preservation of human life demands that none but competent and properly qualified physicians and surgeons shall be allowed to practice their profession,

SECTION 1. Be it enacted by the Senate and House of Representatives of the Commonwealth of Pennsylvania in General Assembly met, and it is hereby enacted by the authority of the same, That there shall be established a Medical Council of Pennsylvania, consisting of the Lieutenant Governor, the Attorney General, the Secretary of Internal Affairs, the Superintendent of Public Instruction, and the President of the State Board of Health and Vital Statistics, and the presidents of the three State Boards of Medical Examiners provided for in this act.

SEC. 2. The said council shall be known by the name and style of the Medical Council of Pennsylvania, and may make and adopt all necessary rules and regulations and by-laws not inconsistent with the constitution and laws of this Commonwealth or of the United States, and shall have power to locate and maintain an office within this State for the transaction of business. Five members of the said council shall constitute a quorum for the transaction of business.

SEC. 3. The said council shall organize at Harrisburg within ten days from the date of the organization of three boards of medical examiners, and shall elect from its own number a president and a secretary, who shall also act as treasurer, both of whom shall hold their offices for one year or until their successors are chosen.

SEC. 4. The members of the said council shall receive no salary, except the secretary and treasurer, who shall receive a salary of not over five hundred dollars, and who shall file with the president of the council a bond in the sum of one thousand dollars, conditioned for the faithful performance of his duties. The necessary expenses of the said council shall be paid out of the appropriation made in section sixteen of this act, and any balance remaining from the appropriation after the disbursements herein specified shall be paid into the treasury of the Commonwealth.

SEC. 5. The said medical council shall hold two stated meetings in each year at Harrisburg, and may hold special meetings at such times and places as it may deem proper. It shall supervise the examinations conducted by the three State Boards of Medical Examiners of all applicants for license to practice medicine and surgery in this Commonwealth, and shall issue licenses to practice medicine and surgery to such applicants as have presented satisfactory and properly certified copies of licenses from State Board of Medical Examiners or State Boards of Health of other States, as provided for in section thirteen of this act, or as have successfully passed the examination of one of the three State Boards of Medical Examiners, but all such examinations shall be made by the State Boards of Medical Examiners established in section six of this act. And the said Medical Council shall have no power, duty, or function except such powers, duties, and functions as pertain to the supervision of the examinations of applicants for licenses to practice medicine and surgery and to the issuing of licenses to such applicants as have successfully passed the examination of one of the State Boards of Medical Examiners or have presented satisfactory and properly certified copies of licenses from State Boards of Medical Examiners or State Boards of Health of other States, as provided for in section thirteen of this act.

SEC. 6. It is further enacted that from and after the first day of March, anno Domini one thousand eight hundred and ninety-four, there shall be and continue to be three separate boards of Medical Examiners for the State of Pennsylvania, one representing the Medical Society of the State of Pennsylvania, one representing the Homœopathic Medical Society of the State of Pennsylvania, one representing the Eclectic Society of the State of Pennsylvania.

Each board shall consist of seven members, and each of said members shall serve for a term of three years from the first day of March next after his appointment, with the exception of those first appointed, who shall serve as follows: Two of each board for one year, two of each board for two years, and three of each board for three years from the first day of March, anno Domini one thousand eight hundred and ninety-four.

The Governor shall appoint the members of said boards of examiners respectively from the full lists of the members of the said medical societies, which lists shall on or before the first day of January, one thousand eight hundred and ninety-four, and annually thereafter, be transmitted to the Governor under the seal and signed by the secretary of the society so nominating. From these lists of nominees respectively the Governor shall during the month of January, anno Domini one thousand eight hundred and ninety-four, appoint three separate boards of medical examiners, each board to be composed exclusively of members of the same medical society. In case of failure of any or all of said medical societies to submit lists as aforesaid, the Governor shall appoint members in good standing of the corresponding society or societies entitled to nominate without other restriction. Each one of the said appointees must be a registered physician in good standing and shall have practiced medicine or surgery under the laws of this State for a period of not less than ten years prior to such appointment.

The Governor shall fill vacancies, by death or otherwise, for unexpired terms of said examiners from the respective lists submitted by the said medical societies, and may remove any member of any said boards for continued neglect of the duties required by this act or on recommendation of the medical society of which said members may be in affiliation, for unprofessional or dishonorable conduct.

The Governor shall in his first appointments designate the number of years for which each appointee shall serve. The appointments of successors to those members whose term of office will expire on the first day of March of each year shall be made by the Governor during

the month of January of each year upon the same conditions and requirements as hereinbefore specified with reference to the appointment of three separate examining boards, each to be composed exclusively of members of the same medical school and society as hereinbefore provided.

SEC. 7. Said boards shall be known by the name and style of Boards of Medical Examiners of the State of Pennsylvania. Every person who shall be appointed to serve on either of said boards shall receive a certificate of appointment from the Secretary of the Commonwealth.

Each of said boards shall be authorized to take testimony concerning all matters within its jurisdiction, and the presiding officer for the time being of either of said boards or of any of the committees thereof may issue subpoenas and administer oaths to witnesses. Each of said boards of examiners shall make and adopt all necessary rules, regulations, and by-laws, not inconsistent with the constitution and laws of this State or of the United States, whereby to perform the duties and transact the business required under the provisions of this act, said rules, regulations, and by-laws to be subject to the approval of the Medical Council of Pennsylvania established by this act.

SEC. 8. From the fees provided by this act the respective boards may pay, not to exceed said income, all proper expenses incurred by its provisions, and if any surplus above said expenses shall remain at the end of any year it shall be apportioned among said examiners pro rata according to the number of candidates examined by each; provided that the Medical Council shall keep separate accounts of all fees received from physicians applying for licenses to practice medicine and surgery, and shall not devote any such fees to the uses of the council or to the uses or remuneration of any other examining board than that of the society with which the physician who pays the fee wishes to be affiliated.

SEC. 9. The first meeting of each of the examining boards respectively shall be held on the first Tuesday of April, one thousand eight hundred and ninety-four, suitable notice in the usual form being given with the notice of their appointment by the Secretary of Commonwealth to each of the members thereof, specifying the time and place of meeting.

At the first meeting of each of the boards respectively an organization shall be effected by the election from their own membership of a president and secretary. For the purpose of examining applicants for license, each of said boards of medical examiners shall hold two or more stated or special meetings in each year, due notice of which shall be made public at such times and places as they may determine. At said stated or special meetings a majority of the members of the board shall constitute a quorum thereof, but the examination may be conducted by a committee of one or more members of the board of examiners duly authorized by said boards.

SEC. 10. The several boards of medical examiners shall, not less than one week prior to each examination, submit to the Medical Council of Pennsylvania questions for thorough examinations in anatomy, physiology, hygiene, chemistry, surgery, obstetrics, pathology, diagnosis, therapeutics, practice of medicine, and materia medica. From the lists of questions so submitted the council shall select the questions for each examination, and such questions for each examination shall be the same for all candidates, except in the departments of therapeutics, practice of medicine, and materia medica the questions shall be in harmony with the teachings of the school selected by the candidate.

SEC. 11. Said examinations shall be conducted in writing in accordance with the rules and regulations prescribed by the Medical Council of Pennsylvania, and shall embrace the subjects named in section ten of this act. After each such examination the board having charge thereof shall without unnecessary delay act upon the same. An official report of such action, signed by the president, secretary, and each acting member of said board of medical examiners, stating the examination average of each candidate in each branch, the general average, and the result of the examination, whether successful or unsuccessful, shall be transmitted to the Medical Council. Said report shall embrace all the examination papers, questions, and answers thereto. All such examination papers shall be kept for reference and inspection for a period of not less than five years,

SEC. 12. On receiving from any of said boards of medical examiners such official report of the examination of any applicant for license the Medical Council shall issue forthwith to each applicant who shall have been returned as having successfully passed said examination, and who shall have been adjudged by the Medical Council to be duly qualified for the practice of medicine, a license to practice medicine and surgery in the State of Pennsylvania. The Medical Council shall require the same standard of qualifications from all candidates except in the departments of therapeutics, practice of medicine, and materia medica, in which the standard shall be determined by each of the boards respectively. Every license to practice medicine and surgery issued pursuant to this act shall be subscribed by the officers of the Medical Council and by each medical examiner who reported the licensee as having successfully passed said examinations. It shall also have affixed to it by the person authorized to affix the same the seal of the Commonwealth.

Before said license shall be issued it shall be recorded in a book to be kept in the office of the Medical Council, and the number of the book and page therein containing said recorded copy shall be noted upon the face of said license. Said records shall be open to public inspection under proper restrictions as to their safe keeping, and in all legal proceedings shall have the same weight as evidence that is given to the conveyance of land.

SEC. 13. From and after the first day of July, anno Domini one thousand eight hundred and ninety-four, any person not theretofore authorized to practice medicine and surgery in this State and desiring to enter upon such practice may deliver to the Secretary of the Medical Council, upon the payment of a fee of twenty-five dollars, a written application for license, together with satisfactory proof that the applicant is more than twenty-one years of age, is of good moral character, has obtained a competent common-school education, and has received a diploma conferring the degree of medicine from some legally incorporated medical college of the United States or a diploma or license conferring the full right to practice all the branches of medicine and surgery in some foreign country. Applicants who shall have received their degree in medicine after the first day of July, one thousand eight hundred and ninety-four, must have pursued the study of medicine for at least three years, including three regular courses of lectures in different years in some legally incorporated medical college or colleges prior to the granting of said diploma or foreign license; and after the first day of July, eighteen hundred and ninety-five, such applicants must have pursued the study of medicine for at least four years, including three regular courses of lectures in different years in some legally incorporated medical college or colleges prior to the granting of said diploma or foreign license. Such proof shall be made, if required, upon affidavit. Upon the making of said payment and proof the Medical Council, if satisfied with the same, shall issue to said applicant an order for examination before such one of the State Boards of Medical Examiners as the applicant for license may select. In case of failure at any such examination the candidate, after the expiration of six months and within two years, shall have the privilege of a second examination by the same board to which application was first made without the payment of an additional fee. And it is further provided that applicants examined and licensed by State Boards of Medical Examiners or State Boards of Health of other States, on payment of a fee of fifteen dollars to the Medical Council and on filing in the office of the Medical Council a copy of said license certified by the affidavit of the president or secretary of such board, showing also that the standard of acquisitions adopted by said State Board of Medical Examiners or State Board of Health is substantially the same as is provided by sections eleven, twelve, and thirteen of this act, shall without further examination receive a license conferring on the holder thereof all rights and privileges provided by sections fourteen and fifteen of this act.

SEC. 14. From and after the first day of March, anno Domini one thousand eight hundred and ninety-four, no person shall enter upon the practice of medicine or surgery in the State of Pennsylvania unless he or she has complied with the provisions of this act and shall have exhibited to the prothonotary of the court of common pleas of the county in which he or she desires to practice medicine or surgery a license duly granted to him or her as hereinbefore provided, whereupon he or she

shall be entitled, upon the payment of one dollar, to be duly registered in the office of the prothonotary of the court of common pleas in the said county, and any person violating any of the provisions of this act shall be guilty of a misdemeanor, and upon conviction thereof in the court of quarter sessions of the county wherein the offense shall have been committed shall pay a fine of not more than five hundred dollars for each offense.

Sec. 15. Nothing in this act shall be construed to interfere with or punish commissioned medical officers serving in the army or navy of the United States or in the United States Marine-Hospital Service while so commissioned, or medical examiners of relief departments of railroad companies while so employed, or any one while actually serving as a member of the resident medical staff of any legally incorporated hospital, or any legally qualified and registered dentist exclusively engaged in the practice of dentistry, nor shall it interfere with or prevent the dispensing and sale of medicines or medical appliances by apothecaries or pharmacists, or interfere with the manufacturers of artificial eyes, limbs, or orthopedic instruments of any kind from fitting such instruments on persons in need thereof, or any lawfully qualified physicians and surgeons residing in other States or countries meeting registered physicians of this State in consultation, or any physician or surgeon residing on the border of a neighboring State and duly authorized under the laws thereof to practice medicine and surgery therein whose practice extends into the limits of this State, provided that such practitioner shall not open an office or appoint a place to meet patients or receive calls within the limits of Pennsylvania, or physicians duly registered in one county of this State called to attend cases in another county but not residing or opening an office therein. And nothing in this act shall be construed to prohibit the practice of medicine and surgery within this Commonwealth by any practitioner who shall have been duly registered before the first day of March, anno Domini one thousand eight hundred and ninety-four, according to the terms of the act entitled "An act to provide for the registration of all practitioners of medicine and surgery," approved the eighth day of June, anno Domini one thousand eight hundred and eighty-one, and one such registry shall be sufficient warrant to practice medicine and surgery in any county in this Commonwealth.

Sec. 16. The sum of two thousand dollars is hereby appropriated out of any moneys in the State treasury not otherwise appropriated for the salary of the secretary and treasurer of said medical council and the necessary expenses of said council, one thousand dollars thereof for the year beginning January first, one thousand eight hundred and ninety-four, and one thousand dollars thereof for the year beginning January first, one thousand eight hundred and ninety-five.

Sec. 17. All acts or parts of acts of Assembly inconsistent herewith shall be and are hereby repealed.

Suprapubic Cystotomy in Two Stages.—In an article published in the *Philadelphia Medical News* for July 1st, Professor Nicholas Senn, of Chicago, remarks that suprapubic cystotomy for the removal of stone in the bladder, the operative treatment of intravesical tumors, or the formation of a temporary or permanent fistula in obstructive diseases due to enlarged prostate, has become a legitimate and permanent procedure in surgery. The technique of the operation is destined to undergo improvement. Distention of the bladder and rectum renders the prevesical space more accessible, and Trendelenburg's posture is of great value in all suprapubic intravesical operations. If the bladder itself is healthy, the high entrance into the organ for therapeutic purposes can be effected with little or no immediate or remote risk to life. In such cases the ideal after-treatment would be suturing of the vesical and external wounds, thus placing the parts in a condition for healing of the visceral wound by primary intention. Such a result has been obtained only in exceptional cases, even by surgeons of large experience and specially skilled in the performance of the operation.

Attempts have been made to prevent contact of septic urine with the recent wound by resorting to drainage of the ureters after suprapubic cystotomy. C. Willems advocates this practice, which, he states, is a delicate yet perfectly practicable procedure. In hypogastric lithotomy it is advisable whenever union of the wound in the bladder is important and subject to prejudicial influences—in fact, whenever the

urine is unhealthy and septic. The ureters should also be drained after the removal of the vesical tumor, whether by hypogastric or perineal incision. The wound is thus protected from contact with morbid urine, and antiseptic plugging of the vesical cavity is permitted.

The patient is placed in the Trendelenburg posture, the pelvis being raised about fifteen inches from the table. The abdominal viscera no longer press the walls of the bladder in contact, and the trigone can readily be seen through the hypogastric incision. A catheter with a Y-shaped extremity is then passed backward through the urethra. The two branches are next introduced into the ureters. The procedure is a delicate one; the upper part of the mucous fold over the orifice of the ureter must be seized with forceps of the kind used for fixing the conjunctiva oculi. Otherwise the very movable vesical mucous membrane may be pushed forward. As the vesical part of the ureter is a narrow funnel, the passage of the catheter needs skillful manipulation. The ureter tolerates the catheter very fairly. In a case of Pawlik's the woman tolerated its presence for forty-eight hours; in Schede's (operation for utero-vaginal fistula), for seven days; and in Albarra's (also in a woman), for ten days. The catheter thus allows full time for perfect union of the vesical wound.

This after-treatment is too complicated and difficult for the average surgeon, and in many cases of septic cystitis it is not applicable. Most surgeons have therefore discarded primary suturing of the visceral wound and rely on drainage and healing by secondary intention. Healing of the wound usually takes place in from four to eight weeks. Future research and experience will undoubtedly enable us to devise some means by which primary healing of the wound will be the rule and not the exception in such cases, and thus shorten the period of recovery to a minimum. The matter is, however, entirely different when suprapubic cystotomy is performed in a case in which the bladder is the seat of a septic cystitis, and such cases most frequently require the services of the surgeon. The adipose and loose connective tissue in the prevesical space, which constitutes a considerable part of the suprapubic route into the bladder, is exceedingly susceptible to infection with pathogenic microbes. The urine in such cases is ammoniacal, toxic, and irritating, and, when brought in contact with the prevesical tissues, exceedingly prone to cause necrosis. The pus microbes contained in decomposed, putrid urine find in the prevesical space the most favorable conditions for the exercise of their specific pathogenic properties. Under such circumstances the wound frequently becomes the seat of sloughing and phlegmonous inflammation, in spite of the most rigid precautions. Suturing of the margins of the vesical wound to the abdominal incision furnishes no protection against this complication. The same can be said of drainage of the bladder and packing of the wound with iodoform gauze. The author has lost two patients from extensive sloughing of the prevesical and paravesical connective tissue. In one case the post-mortem showed that the base of the bladder was nearly separated from the surrounding tissues by extensive necrosis of the adipose and connective tissue interposed between them. It has occurred to him that this source of danger might be successfully avoided by performing the operation in two stages, and he has resorted to this modification in a number of instances, with most gratifying results.

The modification of the operation that he proposes is based on the familiar surgical fact that granulating surfaces furnish an almost absolute protection against infection. The first operation is performed under the influence of an anesthetic. The rectum and bladder are distended in the usual manner. The field of operation is rendered aseptic, and the bladder is exposed freely by dissecting away the prevesical fat over an oval surface about two inches in length and half as wide. After the hemorrhage is arrested the wound is firmly packed with iodoform gauze. The external dressing should be securely fastened by strips of adhesive plaster, which are made to encircle the pelvis and which prevent the dressing from becoming displaced. At the end of five days the dressing and iodoform gauze are removed and the bladder is distended and incised without the use of an anesthetic, if it is intended to simply establish a suprapubic fistula, or if a small stone is to be removed. More serious intravesical operations would require the use of an anesthetic. If the wound has remained aseptic it will now be found covered throughout by a layer of active granulations. These granulations have closed the connective-tissue channels, and have shut

out from the wound the balance of the prevesical space. If no anæsthetic is used, the surface of the wound is brushed over with a five-per-cent. solution of cocaine five minutes before the operation. The bladder and rectum are distended in order to render the anterior wall of the bladder more accessible. The bladder is incised and drained in the usual manner. The septic urine is harmless to the granulations, and thus the dangers of the operation are minimized.

It must be admitted that in patients greatly debilitated by the disease that rendered the operation necessary, the immediate risk of the operation is greatly diminished by performing it in two stages. Another great advantage accruing from this modification of the operation is that at the time the second step is carried out the wound is already in a favorable condition for definite healing. For the purpose of illustrating the value of this modification of performing suprapubic cystotomy in affections of the bladder complicated by septic cystitis, Dr. Senn briefly reports two cases that have recently come under his observation.

He formulates the following conclusions for further deliberation :

1. Necrosis and phlegmonous inflammation of the margins of the wound and the tissues in the prevesical space (cavum Retzii) not infrequently occur as complications of suprapubic cystotomy, if the operation is performed for affections complicated by septic cystitis.
2. Suprapubic cystotomy in two stages greatly diminishes, if it does not entirely overcome, this source of danger.
3. In the first operation the bladder is freely exposed in the usual manner, when the prevesical fat is dissected away over a vertical oval space at a point corresponding to the location of the proposed visceral incision, after which the wound is packed with iodoform gauze, and the external dressing is applied in such a manner that it can not become displaced.
4. The incision in the bladder and the intravesical operation are postponed until the external wound has become covered with a layer of active granulations, which usually requires from four to six days.
5. The second operation can be performed with the aid of cocaine, without general anæsthesia.
6. This modification of suprapubic cystotomy diminishes the immediate risks of the operation, and affords protection against a number of serious *post-operationem* complications.

Chronic Tropical Diarrhœa as it Occurs among the Natives of India is the subject of an article by Mr. A. P. Das, L. M. S., published in the *Calcutta Medical Reporter* for June 1st.

This disease, he says, is called diarrhœa alba from the white nature of the stools, and it is also called morning diarrhœa from the purging which occurs frequently in the early morning. By the *Kabiraj* it is called *grihiyeng* ; by the Chinese, *spane* ; and by the Himalayan tribes, *hill diarrhœa*.

Malaria is often a predisposing as well as an exciting cause of this disease, as we often find chronic diarrhœa coming on after an attack of remittent or intermittent fever, when the health is broken down. In some constitutions slow malaria working latently in the system causes congestion of the abdominal viscera, especially of the liver, and disorders of the chylipoietic system. When the system has thus been predisposed, alternations of temperature, exposure to damp, cold, irregularities of diet, drink, excessive exercise, bad water, or emanations from decomposing animal or vegetable matter which would have been innocuous under other circumstances, often produce that amount of unbalanced exosmosis called *flux*. In females, after childbirth or during lactation, when the system is debilitated, this disease slowly takes its root ; beginning with indigestion and acidity, but terminating in chronic tropical diarrhœa. Sometimes when simple diarrhœa has been neglected it takes on a chronic form, or when a patient has had several attacks of dysentery his system becomes susceptible to chronic diarrhœa. Slight irregularities of diet or exposure to cold or chill predispose to chronic diarrhœa and dysentery.

The gastric and pancreatic secretions, the bile, and the secretions from the intestinal follicles and glands become deteriorated. Gastric and intestinal digestion is imperfectly performed, while the power of absorption by the villi and veins of the intestines is diminished, especially when the disease becomes chronic. There is always conges-

tion of the intestinal vessels owing to the sluggish condition of the portal circulation. Atrophy of the secreting structure of the stomach, pancreas, and liver, also the villi, the follicles of Lieberkühn's solitary and agminate glands of the intestines, and the shedding of the epithelium of the villi are remarkable, but the reproduction is slow. Here and there we find the epithelium of the intestine is denuded, and small ulcers throughout the small and large intestines are observed. At last the secreting cells of the liver, stomach, pancreas, follicular and lenticular glands of the intestines and the absorbent structures of the villi undergo fatty and granular degeneration, or, as sometimes happens, the minute vessels of the villi become infiltrated with amyloid material, when the pathological condition becomes grave.

Sometimes chronic diarrhœa is complicated with organic disease of the liver and kidney, or both, when the prognosis is unfavorable. Similarly this disease is complicated with tuberculosis and pernicious anæmia. Cancrum oris is one of the rare complications.

At the early stage of the disease there are malaise and uneasiness, loss of or impaired appetite, a sense of fullness or distention after meals relieved by eructation, irregular action of the bowels ; sometimes the first motion is semi-liquid and the successive motions are loose. At first the motions are four or five in twenty-four hours ; afterward they range to ten or twelve in a day.

The motions are clay-colored, white, offensive, liquid, and passed generally in the early morning with a copious escape of flatus. They are copious, white, liquid evacuations when only liquid food is allowed, or henteric in proportion to the amount of solid material taken. There is portal plethora with or without hemorrhoidal tendency. The tongue is coated white and the taste is depraved. Sometimes the tongue is red and sore, indicating the denuded condition of the intestines. Uneasiness and griping in the abdomen are sometimes complained of, and sickness, horborygni, and thirst are prominent symptoms at all stages. In this state the patient may go on for weeks and months until his health is shattered and he becomes incapable of work, when anæmia, as indicated by pallor of the face, lips, and conjunctiva, shows itself.

In the advanced stage the motions are painless, more frequent, watery, copious, white, and of offensive smell. Sometimes the motions contain blood, mucus, or gelatinoid exudations. If there is dysenteric complications the patient will complain of pain and gripes during evacuations. Extreme anæmia and debility set in, the red blood-corpuscles become deficient in number and color, and there is attenuation of the albumin of the blood. Sometimes the conjunctiva is tinged yellow, tongue red, smooth and shining, and destitute in great part of epithelium. Thirst and sickness are excessive, pulse weak, feeble, and compressible, palpitation, giddiness on slight exertion ; urine scanty, high-colored, and sometimes with deposit of urates and lithates ; hollow cheeks, sunken eyes, and pinched face are always remarkable ; skin is dry and parched, perspiration checked. Temperature normal or subnormal, or slight rise during the night. There is tenderness over the cæcum, colon, or ileum. In some cases the liver and spleen are enlarged, but in the majority of cases the liver is tender and painful on pressure. Emaciation and wasting are extreme. There is a tendency to swelling of the feet, and local anasarca may run up to the knee ; but rarely is there any effusion into the serous cavities, unless the case is complicated with cirrhosis of liver or Bright's disease. At this advanced stage food when taken is not assimilated, on account of the atrophic condition of the glands of the stomach and intestines.

Sir Joseph Fayrer and Dr. Joseph Ewart, in their elaborate papers on chronic tropical diarrhœa as it occurs among the Europeans in India, read before the Medical Congress at Copenhagen in 1884, alluded to the pigmentation of the skin and purpuric or scorbutic effusion of blood under the skin, but these symptoms are rarely to be found among the natives of India, on account of the peculiar nature and tint of their skin.

By the history of the case, by the nature and frequency of the stools, we can arrive at an early and easy diagnosis.

The prognosis depends upon the complications. If chronic diarrhœa is attended with amyloid degeneration, the prognosis is grave ; also if there is any cirrhosis of the liver, chronic or acute Bright's disease, or tuberculosis of the lung or pernicious anæmia. In the aged the prognosis is unfavorable.

Our old plan of treatment with opiates and astringents with a mixed dietary is not efficacious for these cases, but our new plan is only an imitation of what *Kabirajs* have practiced from bygone times, though the profession is indebted to Sir Joseph Fayrer and Dr. Joseph Ewart for the new mode of treatment with milk and milk only.

In mild cases, *bael* in some shape, combined with milk diet, will have a good effect. Of *bael* he prefers an ounce of the pulp of the ripe fruit, in the shape of sherbet, morning and evening. If the ripe fruit is not procurable, the liquid extract of *bael*, a drachm dose, or *bael* powder a teaspoonful twice daily can replace it. Milk, fresh and boiled, is preferable. About three fourths or one seer in twenty-four hours, in divided doses at the commencement, to be increased gradually as the digestive power will increase. If there is any exacerbation in the evening, a two-grain quinine pill once in the morning, for about a week or two, will check it.

From the day milk diet is given, distinct effects will be noticed in the patient, who will sleep well, and will obtain rest from his abdominal troubles, the motions will decrease in number, and will be consistent. These effects will be noticeable a week after the commencement of the milk treatment, sometimes earlier or later. Sometimes on the continuation of milk diet the bowels get constipated; then a dose of castor oil—say four drachms—in the early morning is advisable. In these cases milk is preferable for the reason that the stomach is weak like a child's stomach, and as milk is our rudimentary food which Nature has put before us for its easy digestibility, it agrees very well. Sage, arrowroot, or other starchy diet will do mischief at the first stage of treatment.

In severe cases, when there is any congestion or enlargement of the liver, a minute dose of calomel, an eighth to a sixth of a grain, or liq. hydrarg. perchloridi, five to eight minims, twice daily, acts like a charm. Mercury acts as an alternative, also as an intestinal antiseptic, and it has a specific action over the liver.

In some cases the irritability and the peristaltic action of the intestines is so aggravated that milk when taken is hurried down for evacuation, when a five-drop dose of liq. opii or tinct. opii (B. P.), twice daily, will prove beneficial, increasing absorption by lessening the peristaltic action of the intestines.

In all cases, and at all stages, a strict milk diet should be continued till the health improves, or till the sores in the mouth are better, and are replaced by natural epithelium. Keep the patient on milk diet for thirty to forty days.

Rest is very necessary. Exposure to cold draughts or chill is injurious. Keep the body well covered and put the patient in a well-ventilated room. Drinking much cold water, soda water, or strong tea is objectionable. Sponging the body with tepid water is an auxiliary step toward cure.

During the convalescent stage, gentle exercise, change of air, regulated diet, and some ferruginous tonics, such as dialyzed iron, ferri et pot. tart., five grains, with an ounce of infusion of *calumba*, twice daily, will hasten the cure.

"Red Chromidrosis."—This is the title of an article contributed by Dr. M. B. Hartzell to the July number of the *University Medical Magazine*. It is much to the author's credit that he puts a question-mark after the title, although only on pathological grounds—namely, that the disease, of which he gives notes of three cases, is not a true chromidrosis, for the sudoriparous glands are not affected, or, at most, play only a secondary part in the production of its phenomena.

"In none of these cases," he continues, "was the sweat colored at the time of its excretion, but it seemed to act as a solvent for the coloring matter present in the small excrecences upon the axillary and perineal hairs.

"A microscopical examination of the nodules with a magnification of two hundred diameters shows that the fungus began to grow upon the surface of the hair, but with the growth of the parasite the hair itself was penetrated, being split up into numerous small fibers, and, in the case of the perineal hairs, fracture of the hair shaft occurred with the production of brush-like ends in which the small brown mass was lodged. In the larger nodules a magnification of some eight hundred diameters showed numerous parallel striae running at right angles

to the shaft of the hair, while in the fine colorless hairs upon which the fungus was just beginning to grow a fine dotted appearance was seen.

"Upon subjecting the hair to the action of liquor potasse and afterward crushing the nodules thoroughly upon a slide, staining with safranin and mounting in glycerin, a high power showed that the mass was composed of numerous micrococci which grew between the fibers of the hair and around the shaft, and were held together by a yellowish or orange-colored amorphous substance. A few attempts at culture upon sterilized potato at the ordinary house temperature were made, but without success.

"Dr. Kneass, who kindly undertook to make some culture experiments for me in the pathological laboratory of the University of Pennsylvania, succeeded in cultivating the fungus upon sugar at a temperature of 37° C. The fungus began to grow within a few hours after implantation, but instead of the brown or orange color, as seen upon the hair, it was sulphur-yellow. Examination of pure cultures showed the cocci frequently arranged in pairs and tetrads, resembling in this respect the *Micrococcus tetragonus*. As the same fungus was obtained from the hair of different patients, it is fair to presume that this micrococcus is the one concerned in the production of the nodules upon the hairs. Upon coagulated albumin the fungus grew much more slowly.

"Although this malady has been known for some time, its true nature has only been determined within a comparatively recent period. Hoffman and Pick, in Germany, and Babes, in France, first pointed out that the red color was due to a fungus growing upon the hair, which the last-named author succeeded in cultivating upon coagulated albumin. The pigment, according to Babes, who examined it spectroscopically, resembles that produced by the *Micrococcus prodigiosus*, the fungus concerned in the production of the so-called 'bleeding host.' The identity of the two organisms, however, has not yet been proved. By scraping the epidermis in the axillary and perineal regions, organisms similar to those upon the hair have been found, but not all of these were pigmented—many of them were colorless. Balzer and Barthelemy, who have also studied the matter carefully, are of the opinion that it is much more frequent than is commonly supposed, since they were able to collect a considerable number of cases by examining individuals at random. The pigment is not always red, but may be of a yellow hue, and these authors found instances in which the parasite was present upon the axillary hairs without any pigment accompanying it. In most cases the sweat is usually abundant, but it is not yet known whether qualitative changes in this excretion are necessary for the production of the disease.

"It would seem that blondes are more frequently affected than brunettes, and that weakness and debility are predisposing conditions, although the robust are not exempt.

"As has already been mentioned, the sweat is colorless upon its excretion, and for this reason the name chromidrosis should be abandoned; the malady is, in fact, one of the hairs, and not of the sweat-gland.

"As the disease is not attended with any annoying symptoms, treatment is rarely sought unless the staining of the underwear is considerable. In the writer's cases alcoholic solutions of bichloride of mercury, two to three grains to the ounce, were employed as lotions with some degree of success; but much more speedy results would probably be obtained by first shaving the affected regions, as in this manner a large part of the fungus would be removed at once."

The Mitchell District Medical Society held its twenty-third annual meeting in West Baden Springs, Indiana, on Wednesday, Thursday, and Friday, the 12th, 13th, and 14th inst., under the presidency of Dr. Dudley S. Reynolds, of Louisville. The programme includes the following titles:

Early Amputation in Railway Injuries, by Dr. E. P. Easley, of New Albany, Ind.; Tuberculous Bone and its Early Removal, by Dr. Merrill Ricketts, of Cincinnati; Cases in Surgery, by Dr. ApMorgan Vance, of Louisville; Surgery of the Tendons, by Dr. John B. Hamilton, of Chicago; Tuberculosis of Bones and Joints, with Clinical Illustrations, by Dr. Nicholas Senn, of Milwaukee; Malignant Growths, by Dr. J. M. Kyle, of Aurora, Ind.; Mechanical Devices in Intestinal Anastomosis,

by Dr. H. Horace Grant, of Louisville; Practical Points in Rectal Surgery, by Dr. J. M. Matthews, of Louisville; Indications for the Operation for Laceration of the Cervix, by Dr. T. S. Galbraith, of Seymour, Ind.; Emergencies in Railway Surgery, by Dr. W. Patton Griffiths, of Louisville; Quinsy, by Dr. Allan Pierson, of Indianapolis; New Therapeutic Points, by Dr. I. N. Love, of St. Louis; Heroes of Peace, by Dr. Joseph Gardner, of Bedford, Ind.; Nightmare, by Dr. J. S. Moore, of New Hope, Ky.; Hay Fever, by Dr. L. T. Page, of Indianapolis; Report of a Case of Urethral Stricture, with Reflexes on the Nervous System, by Dr. D. C. Peyton, of Jeffersonville, Ind.; Balneotherapy, by Dr. C. G. Comegys, of Cincinnati; Tuberculosis of the Peritonæum, by Dr. H. O. Pantzer, of Indianapolis; Headaches, by Dr. Curran Pope, of Louisville; Experience in Skin Grafting, by Dr. A. M. Owen, of Evansville, Ind.; Tubal Pregnancy, by Dr. H. D. Wood, of Angola; Craniectomy, with Report of Case, by Dr. A. J. Banker, of Columbus, Ind.; Shoulder Presentation in Primipara, with a Case, by Dr. J. C. Pearson, of Mitchell, Ind.; Recurrent Post-partum Hemorrhage, with a Case, by Dr. T. J. Allen, of Mitchell, Ind.; Some Surprises in Prostatic Pathology, by Dr. G. Frank Lydston, of Chicago; The Clinical Aspect and Pathology of Broncho-pneumonia in Children, by Dr. Henry E. Tuley, of Louisville; Is Milk indicated in Typhoid Fever? by Dr. J. H. Stuckey, of Louisville; A Résumé of the Advance in the Department of Diseases of Children, by Dr. John A. Larrabee, of Louisville; Diseases of the Female Urethra, by Dr. L. J. Willien, of Terre Haute, Ind.; Treatment of Fibroid Tumors of the Uterus, by Dr. L. H. Dunning, of Indianapolis; The Indifference of the General Practitioner to the Diseases of Women, by Dr. W. H. Link, of Petersburg, Ind.; Galvanism for Inter-menstrual Pain, by Dr. E. Walker, of Evansville, Ind.; The Eye Clinics of London and Paris, by Dr. W. B. Meany, of Washington; Cases illustrating the Aid of Ophthalmoscopy in Diagnosis, by Dr. S. G. Dabney, of Louisville; Report on Ophthalmology, by Dr. P. Richard Taylor, of Louisville; The Correction of Astigmatic Refraction, by Dr. A. T. Cherry, of Huntington, W. Va.; Some Practical Points in Laryngology and Otology, by Dr. M. F. Coombs, of Louisville; New Devices for the Exploration and Treatment of the Nasal Passages, by Dr. Allan DeVilliss, of Toledo; The Effect of Enlarged Tonsils in Middle-ear Disease, by Dr. L. C. Cline, of Indianapolis; Intubation of the Larynx and Esophagus, by Dr. W. Cheatham, of Louisville; Pessimism in Ear Troubles, by Dr. F. C. Heath, of Indianapolis.

The American Neurological Association.—The next meeting will be held at the West End Hotel, Long Branch, N. J., on July 25th, 26th, and 27th. The annual dinner will be held on the evening of the 26th. The preliminary programme is as follows: The Diagnosis of General Paresis, by Dr. L. C. Gray, of New York; The Genesis of Hallucination, Illusion, and Delusion, by Dr. H. A. Tomlinson, of St. Peter, Minn.; A Study of the Temperature in Twenty-five Cases of General Paralysis of the Insane, by Dr. Frederick Peterson, of New York; Observations on a Case of Myxœdema, by Dr. W. C. Krauss, of Buffalo; The Etiological Significance of Heterogeneous Personality, by Dr. Smith Baker, of Utica; A Tumor involving the Angular Gyrus, by Dr. G. L. Walton, of Boston; A Case of Acromegaly, with Autopsy, by Dr. C. L. Dana, of New York; The Anatomical Changes in the Spinal Cord in an Old Case of Infantile Paralysis—A Contribution to the Cell Grouping in the Cervical Cord, by Dr. Joseph Collins of New York; Some Observations on the Relation of Chorea to Rheumatism, with the Narration of a Case, by Dr. C. Eugene Riggs, of St. Paul; Thyroidectomy in the Treatment of Graves's Disease, by Dr. J. J. Putnam, of Boston; Experiences in the Use of Testiculin and Cerebrin, by Dr. J. J. Putnam, of Boston; Tabes and Syphilis, by Dr. B. Sachs, of New York; The Paracorporeal Fissure, by Dr. B. G. Wilder, of Ithaca; Report of a case of Infectious Endocarditis, with General Septicæmia, complicated with Multiple Neuritis, by Dr. James H. Lloyd, and Dr. David Reisman, of Philadelphia; Progressive Muscular Atrophy—The Pathological Report of Two Cases, with the Exhibition of Microscopical Specimens, by Dr. G. M. Hammond, of New York; Lesion of the Thalamus and Internal Capsule in a Case of Hemianæsthesia, with Notes of Autopsy, by Dr. Charles K. Mills, of Philadelphia; A Report of Two Cases of Friedreich's Ataxia, by Dr. Frank R. Fry, of St. Louis; Exhibition of a Brain from a Case of Mixed Aphasia, with Lesion confined to Broca's

Region, by Dr. George G. Preston, of Baltimore; Peripheral Paralysis after Surgical Operations, by Dr. V. P. Gibney, of New York; A Case of Chorea of Sydenham, with Autopsy, by Dr. C. L. Dana, of New York; A New Form of Pedometer, by Dr. W. C. Krauss, of Buffalo.

The Eleventh International Medical Congress.—The executive committee announces that the congress will undoubtedly be inaugurated on the 24th of September, in the presence of H. M. the King of Italy. They dwell upon this fact particularly because there has been spread the notion of the possibility of the prorogation of this meeting. The executive committee has never deliberated upon a prorogation, but has determined upon the programme, and has taken the necessary steps to get the localities ready for September 24th. The programme will be printed, and colleagues are therefore asked to communicate promptly the titles of their papers, that they may be comprised in the programme. Abstracts and conclusions are to be presented not later than July 31st, as prescribed by Art. 11 of the statutes.

To Contributors and Correspondents.—*The attention of all who purpose favoring us with communications is respectfully called to the following:*

Authors of articles intended for publication under the head of "original contributions" are respectfully informed that, in accepting such articles, we always do so with the understanding that the following conditions are to be observed: (1) when a manuscript is sent to this journal, a similar manuscript or any abstract thereof must not be or have been sent to any other periodical, unless we are specially notified of the fact at the time the article is sent to us; (2) accepted articles are subject to the customary rules of editorial revision, and will be published as promptly as our other engagements will admit of—we can not engage to publish an article in any specified issue; (3) any conditions which an author wishes complied with must be distinctly stated in a communication accompanying the manuscript, and no new conditions can be considered after the manuscript has been put into the type-setters' hands. We are often constrained to decline articles which, although they may be creditable to their authors, are not suitable for publication in this journal, either because they are too long, or are loaded with tabular matter or prolix histories of cases, or deal with subjects of little interest to the medical profession at large. We can not enter into any correspondence concerning our reasons for declining an article.

All letters, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication. No attention will be paid to anonymous communications. Hereafter, correspondents asking for information that we are capable of giving, and that can properly be given in this journal, will be answered by number, a private communication being previously sent to each correspondent informing him under what number the answer to his note is to be looked for. All communications not intended for publication under the author's name are treated as strictly confidential. We can not give advice to laymen as to particular cases or recommend individual practitioners.

Secretaries of medical societies will confer a favor by keeping us informed of the dates of their societies' regular meetings. Brief notifications of matters that are expected to come up at particular meetings will be inserted when they are received in time.

Newsletters and other publications containing matter which the person sending them desires to bring to our notice should be marked. Members of the profession who send us information of matters of interest to our readers will be considered as doing them and us a favor, and, if the space at our command admits of it, we shall take pleasure in inserting the substance of such communications.

All communications intended for the editor should be addressed to him in care of the publishers.

All communications relating to the business of the journal should be addressed to the publishers.

Contributors who wish to order REPRINTS of their articles should do so on a blank prepared for that purpose, which will be sent to them by the publishers on receipt of a request to that effect. The order should be sent to the publishers, and not to the editor.

Original Communications.

NOTES ON

AMERICAN CATHETERS AND BOUGIES.

By J. W. S. GOULEY, M. D.,
SURGEON TO BELLEVUE HOSPITAL.

THE necessity of resorting to artificial means for relief of the distended urinary bladder must have compelled primitive man to improvise hollow cylinders sufficiently long and slender to enable him to pass them into the urethra and thus reach and empty the bladder. These original tubes of many ages past were probably straight, rigid, and non-metallic, but there are abundant proofs that two thousand years ago catheters were straight and curved, rigid and metallic; witness those found in the ruins of Pompeii. The employment of flexible non-metallic instruments appears to be of comparatively recent date. Soft pliable catheters of animal tissue seem to have been made during the eleventh century, but their use did not become general until the latter part of the last century, when they were constructed of woven-silk cylinders coated with an elastic varnish. Apparently the first of these elastic instruments were manufactured by the jeweler Bernard, of Paris, in the year 1779, the suggestion respecting the varnish having been made by Hérissant. Afterward Thedn, of Berlin, carried out Hérissant's idea of using India rubber dissolved in ether, but Bernard had already omitted the India rubber from the component parts of his varnish. In 1785 Pickel, of Würzburg, published the formula for a new varnish into whose composition no India rubber entered, and gave a detailed account of the manner of coating the instruments. Since then many improvements in the details of manufacture have been made, and the so-called gum catheters have gradually replaced metallic instruments in most cases requiring frequent catheterism. Bougies of the same materials were used and are still made to be used instead of the metallic, emplastie, and wax bougies.

Until recently France, Germany, and England seem to have supplied the greater part of the gum catheters and bougies used in different parts of the world. The first large manufactory of catheters in England was established many years ago by a German, Mr. Eschmann, whose successors are still engaged in the extensive manufacture of these instruments. About fifty years ago, says Mr. Stohlmann, soft catheters and bougies were manufactured in the United States by a Frenchman, Mr. Petrie, who had established himself in Philadelphia, but soon gave up the business because the demand for his instruments was too limited, on account perhaps of their being inferior to those imported from France. From that time it does not appear that any attempt was made to manufacture gum catheters in this country until the year 1879, when Mr. Roy, son-in-law of Mr. Bénas, of Paris, established a catheter factory in one of the suburbs of New York, and continued to supply, to a limited extent, the demand for gum catheters until 1890, when his establishment was closed. Thus far

the home manufacture of these catheters had affected but little the importation of French, English, and German catheters.

It has not been possible to obtain strictly accurate information relating to the importation, home manufacture, and consumption of soft catheters and bougies, but some of the merchants and manufacturers assert that the annual sale is about one million soft catheters, of which two hundred thousand are of India rubber, and one hundred and ten thousand bougies. In 1887 the importations of flexible web catheters were about as follows: From England, five hundred and fifty thousand; from France, one hundred and fifty thousand; from Germany, fifty thousand. During the year 1887 the J. Ellwood Lee Company, of Conshohocken, Pennsylvania, began to manufacture web catheters on a small scale; but, having improved the necessary machinery, soon obtained excellent results and so extended their establishment, which is perhaps the largest catheter factory known, as now to be able to manufacture three hundred and seventy-five thousand web catheters and fifty thousand bougies annually. Until the end of 1875 nearly all the soft vulcanized India-rubber catheters used in this country were imported. In 1876 the firm of George Tiemann & Co., of New York, began the manufacture of India-rubber catheters with countersunk blunt-edged eyes under the name of velvet-eyed catheters, and also some catheters of the same material with no lateral eye, but open at the vesical end. The following-named firms have since been engaged in the manufacture of soft-rubber catheters: The Davidson Rubber Company; Parker, Stearns, & Sutton; The Akron Rubber Company; The Tyer Rubber Company; and several other companies. At present, of the two hundred thousand India rubber catheters sold annually in the United States, only thirty thousand are imported. In 1891 the importation and the home manufacture of soft catheters and bougies bore the following proportions:

Cheap commercial catheters, English...	300,000
Better qualities of catheters, English...	40,000
Better qualities of catheters, French...	35,000
Better qualities of catheters, German...	10,000
Soft India-rubber catheters, English...	30,000
Cheap commercial bougies, English...	45,000
Better qualities of bougies—English, French, German	15,000
Total imported.....	475,000

Cheap commercial catheters, American ..	100,000
Better qualities of catheters, American ..	275,000
Soft India-rubber catheters, American ..	170,000
Cheap commercial bougies, American...	30,000
Better qualities of bougies, American...	20,000

Total home-manufactured..... 595,000

Thus in the lapse of a few years this industry has been developed to a degree which has already permitted in a year the exportation of one hundred thousand web catheters to England, Ireland, Scotland, France, Germany, Spain, South America, Australia, and India. There is also a large

export trade in rubber catheters. These American catheters and bougies are fully equal to those manufactured in foreign countries, and some of them are even superior, notably the commercial and the best woven-eye silk catheters, as will be seen by a comparison of the tensile strength and of the quality of the varnish of the different instruments in use. The American (Tiemann's) India-rubber catheters are superior to those of foreign importation in the construction of the eye, in the high polish of their surface, and in the smoothness of their interior.

The substances used for the framework of American web catheters are cotton, flax, ramie, and silk. The labor of weaving the cylinders is nearly the same in all qualities of web catheters, and the same varnishes are used for coating the different grades. The cost of the raw materials and the labor in finishing make the difference in price of the several qualities. In the higher grades of catheters the eye is woven, while in the lower grades the eye is punched.

Within the past few months a new catheter factory has been established in the city of New York under the firm name of C. F. Kingstone, formerly of Roy & Co. The managers are C. Bénas and C. Roy. The quality of catheters and bougies manufactured at the Kingstone establishment is fully equal to that of the best instruments ever made in Paris.

The properties of good web catheters may be stated as follows: 1. They are thoroughly, but not too thickly, coated with varnish inside as well as outside and highly polished; the varnish is pliable, not apt to crack, and resists the action of moist heat up to 212° F. 2. In length they do not exceed thirty-three centimetres (about thirteen inches). 3. In diameter they vary from two to nine millimetres. 4. The distal extremity of their single oval eye is one centimetre from the point, which is smooth and rounded; this eye, in curved, elbowed, and double-elbowed catheters, is generally lateral, but in some of these instruments the eye is superior, corresponding to the concavity of the bend, and in other cases the eye is omitted, the catheter being open at both ends, or, in addition to the eye, the vesical end is open for catheterism upon a whalebone conductor. 5. Good web catheters are firm but pliable, never rigid, from the proximal to the distal end; a web catheter with a rigid vesical extremity is a dangerous instrument, liable to cause false passages in the deeper regions of the urethra. 6. The form of the vesical extremity is in accord with its intended uses; straight web catheters are not so safely and easily used as the curved, elbowed, or double-elbowed, the curved form being the most easily introduced into strictured urethrae and in the majority of cases of enlargement of the prostate. 7. The tensile strength of the different qualities of web catheters was ascertained by experiment to be as follows: The breaking strain of an English commercial catheter was forty-two pounds, the breaking strain of an American commercial catheter was fifty-four pounds, the breaking strain of an American Lisle-thread catheter was fifty-six pounds, the breaking strain of an American silken-linen catheter was sixty pounds, the breaking strain of an English silk-web catheter was eighty-five pounds, and an American silk-web catheter of best quality

was then tested to one hundred and fifteen pounds without breaking, but the varnish was stripped off at each end.

When it is necessary to retain a catheter in the urethra and bladder, the physician should select one which has not been too thickly coated with varnish. The highest grade of catheter is not always the best for this purpose, because in the course of twenty-four hours the urine filters through the internal wall of the catheter, the silk webbing is saturated, swells irregularly, and uplifts here and there the coating of varnish, which soon scales off, while the Lisle-thread, silken-linen, and those silk catheters with thin external coating resist longer the action of the urine, and do not lose their smoothness after being retained forty-eight hours in the bladder. If, however, the interior of all web catheters were thoroughly varnished, and thus rendered impervious to moisture, there would be no irregular uplifting of the surface and no scaling.

The American commercial catheters have lately been much improved in quality, and they may be found very useful in hospital as well as in private practice. Their cost is little as compared to that of the higher grades. A catheter of this kind may be used for a single day and thrown away, or may be repeatedly boiled without injury, and used as long as the surface of the instrument retains its smoothness. These improved instruments are known as "tent-catheters."

No catheter whose surface is fissured or otherwise roughened should be passed into the human urethra, because it would not only irritate this canal, but convey therein septic germs. For general use, physicians will find it advantageous to purchase the higher grades of web catheters, because, with proper care, they last long and retain their suppleness and smoothness. After having used an American silk-web catheter three hundred times, its surface was found to be as smooth as in the beginning. The instrument was then retired from active service to be preserved as an illustration of the excellence of home manufacture. Another American silk catheter was used twelve hundred times by a patient, and was set aside only because its surface had become irregular, although it was not cracked.

It may now be proper to make a few suggestions respecting the kind of care web and soft-rubber catheters require to render their employment safe to patients and easy to physicians:

1. All web catheters should be kept at full length and never coiled; otherwise the varnish will surely crack.

2. Web catheters should be loosely wrapped in *dry* antiseptic gauze and preserved in tightly closed metal cases until wanted for use. After they have been used they should be carefully cleansed, thoroughly dried inside and outside, then replaced in the gauze and case, or they may be carried in hollow walking sticks.

3. Soft-rubber catheters should be kept at full length, never coiled, and should be wrapped in *moist* antiseptic gauze and preserved in tightly corked glass tubes capable of containing three or four catheters, because exposure to the air leads to rapid oxidation, which causes the instruments to become hard and brittle.

4. Before using a rubber or a web catheter it should be dipped for a minute in a one-per-cent. carbolic-acid solution, but not longer, as carbolic acid, even in such a weak solution, acts injuriously upon the varnish of web catheters as well as upon rubber catheters by prolonged contact.

5. Before using a web catheter it should be slightly warmed by friction in the hands and by a momentary immersion in warm one-per-cent. carbolic-acid solution to prevent cracking of the varnish, particularly during cold weather.

6. Web and rubber catheters are much injured by fats of all kinds, by glycerin, by saliva, and by vaseline, which, however, seems to be the least hurtful of these lubricants. If used at all, it should be in the smallest quantity—just enough to very thinly coat the catheter. Some physicians reject not only the fatty but all other lubricants, and think it sufficient to moisten the catheter with warm water. More soft catheters are destroyed by the excessive use of fatty substances than by any of the many other abuses to which they are subjected. Therefore there is need of a lubricant which shall not be irritating to the urethra, and which shall contain no fat and no free alkali to deteriorate the varnish of web catheters and soften rubber catheters. After examining different substances it was thought that a watery solution of dry soap, with the introduction of some ingredient to add lubricity to its viscosity, would be likely to answer the purpose. On consultation with Dr. Charles Rice, the chemist of the Department of Public Charities, the following formula for a saponic lubricant was agreed upon:

White Castile soap, powdered. . . . 360 grains.

Tincture of quillaja (1 in 5). . . . $\frac{1}{2}$ fluidounce.

Water, a sufficient quantity.

(Product, about 1,420 grains.)

Mode of Preparation.—Pour two fluidounces of water into a tared capsule, heat the water to boiling, and add the soap. Continue the heat and stir until a homogeneous jelly is produced, then add enough hot water to make the contents of the capsule weigh two troy ounces and a half (1,200 grains), after which strain the mixture through cotton gauze. Lastly, pour in the quillaja tincture. This mixture when cool has the consistence of thick honey, possesses both viscosity and lubricity in a sufficient degree, and is free from any agent likely to be deleterious to the urethra or to the catheter. It may be preserved in an aseptic state in small collapsible tubes. The lubricant may be perfumed, or one per cent. of pure carbolic acid may be added. Among the experiments tried was an addition to the mixture of two drachms of *Chondrus crispus* jelly (*National Formulary*). This slightly increased the lubricity while it greatly increased the fluidity of the mixture. It is likely that the *Cetraria islandica* will yield similar results.

7. All web catheters are liable to harden and to be unfit for use in the course of a few years, especially when they have not been in daily use. On the first appearance of the hardening process the instruments should be cast aside.

8. Rubber catheters harden and are brittle in about two

years, or even sooner, if unused and exposed to the air. But when daily lubricated with fatty substances they seldom last more than three or four weeks, then swell, lengthen, and undergo a process of softening which renders them liable to be torn across during withdrawal, so that often several inches of this deteriorated rubber remain in the bladder.

9. After using a web catheter it should be well washed by forcing a stream of water through the instrument, which should then be dipped for a minute into a one-per-cent. carbolic-acid solution, thoroughly dried, wrapped in dry antiseptic gauze, and inclosed in a metal case. The drying process is begun by shaking off briskly the last drops of water from the interior of the catheter, which may then be exposed to 120° F. of heat in a dry sterilizer or in any other way that may be safe and convenient.

10. Web catheters, even "ten-cent catheters," may be rendered aseptic also by boiling for ten or fifteen minutes, then drying thoroughly in a sterilizer, when they will be ready for use. During ebullition the catheters should not be coiled, but kept at full length and away from the bottom of the boiler. Dry sterilization may be accomplished as well just before using the catheter, but care should be taken to prevent the instrument from sticking to the metal.

11. Inasmuch as some time is necessarily consumed in the drying process, it is more convenient to a patient who is obliged to catheterize his bladder five or six times every twenty-four hours to be supplied with ten or twelve web catheters (No. 9 or 10 of the English scale), and to use two catheters each day, so that the same catheters may be used only once every five or six days. This plan has been pursued by a number of patients, who have all fully appreciated its advantages. In one of these cases, the patient relieving himself eight times daily, the catheters so used were carefully examined seven months after and found unaltered and in the best condition, each instrument having been used about a hundred and forty times.

American web bougies are made of the same materials as those of catheters. They are therefore of the same grades—cheap commercial cotton, flax, and ramie. A cotton olivary bougie made by the Lee Company happens to be the best for general use. It is solid, slender in the first three inches of its shaft, and consists of a number of layers braided one upon another and coated with the same varnishes as the catheters, but it is distinguished from other bougies by its vermilion color. It has no ivory tip, is completely coated, and therefore easily rendered aseptic. The care of wrapping in gauze and inclosing in a metal tube is needed to preserve the instrument, which should be cast aside if it becomes fissured. It should be slightly warmed before introduction. No fats should be used as lubricants.

Whalebone bougies were used in France early in this century and also in the United States. Dr. H. G. Jameson (*Medical Recorder*, 1827) spoke well of the utility of whalebone bougies of "the size of a small knitting needle" in the treatment of urethral strictures. Whalebone bougies are of two kinds—those with olivary point and elbowed, about one millimetre in diameter, to serve as conductors

for larger instruments, and those for the dilatation of narrow strictures. The second, also elbowed and olive-pointed, are not over one millimetre in diameter for the first three inches, thence increasing gradually in diameter so that at five inches they are equal to Nos. 2, 3, 4, 5, 6, and 7 English scale, the set comprising six bougies as indicated by these numbers. All whalebone bougies require to be thinly coated with carbolized vaseline and preserved in metal tubes; otherwise they become dry and brittle and are soon destroyed by parasites.

THE

DIAGNOSIS OF RENAL INSUFFICIENCY.*

By ALLEN A. JONES, M.D.,

INSTRUCTOR IN PRACTICE, AND CLINICAL INSTRUCTOR IN MEDICINE,
MEDICAL DEPARTMENT, UNIVERSITY OF BUFFALO.

IN the diagnosis of renal insufficiency we consider the symptoms which are remote from the kidneys, and also the immediate renal symptoms as revealed in abnormal conditions of the urine. Sometimes the symptoms and general appearance of a patient lead us to suspect nephritis, but uranalysis in the case gives contradictory evidence. On the other hand, we not infrequently find evidences of organic renal lesion by the examination of the urine in cases presenting very few, if any, symptoms suggesting disease of the kidneys. Too often the diagnosis of renal insufficiency is made only after appreciable albuminuria has been discovered or casts have been found in the urine. Our observations have led us to believe that a large number of individuals suffer from chronic retention of toxic substances which should properly be eliminated by the kidneys, notwithstanding the fact that several uranalyses in such cases fail to reveal the presence of either albumin or casts. There is no great difficulty in diagnosing renal insufficiency, actual or probable, in those cases yielding unmistakable evidence of disease of the kidneys upon cursory examinations of the urine. But in those cases presenting no albuminuria more difficulty arises and more crucial tests must be instituted for signs of renal insufficiency.

Permit me first to refer to some of the more common and prominent symptoms of the toxæmia arising from sluggish renal elimination. Those referable to the digestive organs and to the nervous system are usually quite pronounced, although the whole organism suffers more or less. Different cases present different groups of symptoms, and, indeed, the variety of disturbances depending upon toxæmia of renal origin renders the clinician the more liable to mistake in assigning them to their true cause.

The severest symptoms of uræmia may supervene suddenly in cases having apparently trivial renal incompetence, while, on the contrary, patients with abundant and constant albuminuria and with urine containing many renal casts may live for years with only mild manifestations of uræmia.

The grave convulsions, delirium, and coma appearing suddenly in cases of acute or long-standing well-recognized

nephritis need not here engage our attention, as they are not likely to escape the notice of the most careless clinician. But to those cases wherein the nature of the toxæmia is obscure I ask your attention. Common symptoms observed in these cases are headache, dizziness, and pressure in the head, neuralgias in various regions of the body, persistent insomnia, mental depression, great nervousness, and a host of manifestations ordinarily seen in neurasthenia. The tongue is usually coated and the taste bad. Anorexia, nausea, vomiting, gastralgia, gastric and intestinal flatulence, weight, burning, and uneasiness in the epigastrium, constipation, sometimes diarrhœa; some or all of these may exist. Ocular symptoms may be complained of and albuminuric retinitis may be discovered (1) before albumin and casts appear in the urine. The heart is often weak and the capillary circulation is poor. The skin is dry, harsh, and scaly, or is muddy, loaded, and relaxed. Loss of flesh is common and muscular strength is much impaired, while nervous energy is at a low ebb and general vitality is usually greatly reduced. Anæmia exists in almost all cases, and oxygenation of the blood and tissues is usually deficient.

The diagnosis of renal insufficiency necessarily hinges upon the examination of the urine, and the following classification may afford some clearness in the study of the clinical inferences to be drawn from the various findings by uranalysis:

I. Cases in which are found pronounced and persistent albuminuria with the presence of renal casts.

II. Cases having albuminuria and renal casts incessantly—i. e., at one analysis they are plentiful while at another they are absent.

III. Cases having albuminuria without the presence of casts.

IV. Cases showing the presence of renal casts without albuminuria.

V. Cases presenting neither albuminuria nor casts, but showing a markedly lowered elimination of urea and other solids.

VI. Cases of renal insufficiency from reflex paralysis of, or other interference with, the nerves presiding over the function of the kidney.

Permit me to discuss each of the classes separately and to cite a few illustrative cases.

Class I embraces cases of Bright's disease that are so commonly seen and recognized as to render it superfluous were I to record any in this short paper.

CLASS II. CASE I.—H. C., aged fifty-four years, never severely ill. Has smoked and drank steadily for many years but not to great excess. Lately suffered from repeated attacks of severe gastralgia, during which vomiting occurred. Between the paroxysms of gastralgia appetite was good, but gastric flatulence continued. Is constipated. Pulse of high tension, with arteries sclerosed. Loss of flesh and strength.

Uranalysis, April 4, 1893.—Reaction superacid; very high-colored; specific gravity, 1.020; albumin present in amount proportionate to 0.90 to the litre; total amount in twenty-four hours, 320 c. c.; urea, 10.240 grm. Microscopically, large number of hyaline and slightly granular casts, and calcic oxalate crystals.

* Read before the Erie County Medical Society, June 13, 1893.

Uranalysis, May 5, 1893.—High-colored; specific gravity, 1.029; no albumin; no sugar; total amount, 992 c. c.; urea, 22.816. Microscopically, no casts found.

Uranalysis, May 22, 1893.—Specific gravity, 1.020; no albumin; total amount, 928 c. c.; urea, 20.416 grm. Microscopically, no casts found.

CASE II.—This case occurred in the practice of Dr. Rochester, and he very kindly handed me the following report. I also made several urinalyses in this case:

Mrs. L., symptoms: persistent vomiting, occasional diarrhoea, headache, dizziness, insomnia, inability to stand on account of muscular weakness of legs. Physical examination showed evidence of chronic bronchitis and asthma, very weak heart with mitral insufficiency. Had attacks of angina pectoris. Skin yellow, thick, and very inactive.

Uranalysis, September 25, 1892.—Volume in twenty-four hours, 960 c. c.; color, iv Vogel; odor, urinous; reaction, acid; specific gravity, 1.003; urea, 6.48 grm.; albumin, trace; sugar, none; small granular casts.

Uranalysis, October 2, 1892.—Specific gravity, 1.005; no albumin; volume in twenty-four hours, 1,200 c. c.; urea, 2.00 grm.; no casts.

Uranalysis, October 23, 1892.—Volume in twenty-four hours, 1,680 c. c.; specific gravity, 1.005; urea, 5.67 grm.; albumin present; granular and epithelial casts.

Uranalysis, October 30, 1892.—Volume in twenty-four hours, 800 c. c.; specific gravity, 1.005; urea, 3.24 grm.; no albumin; no casts.

CASE III. CASE I.—Mrs. J. C., aged thirty; pregnant seven months with fourth child. Symptoms, violent and persistent headache with restlessness, insomnia, anorexia, coated tongue, vomiting, and constipation.

Uranalysis, May 2, 1892.—Reaction mildly acid; high-colored; specific gravity, 1.015; albumin present in moderate quantity; no sugar; no casts found.

Uranalysis, May 19, 1892.—Reaction somewhat superacid, high-colored and smoky; specific gravity, 1.018; albumin, small amount; no sugar; no casts found.

Several subsequent examinations of this patient's urine revealed the presence of albumin without renal casts.

CASE IV. CASE I.—F. W., aged twenty-six. Complained much of his stomach for several months and had used the stomach-tube for relief. Had nausea and some gastric pain. Bowels obstinately constipated; skin very dry and scaly. Nervousness and sleeplessness existed, with general mental and physical wretchedness. Pulse tense and heart irritable, pounding, and irregular in rhythm.

Uranalysis, March 31, 1891.—Reaction superacid; specific gravity, 1.022; albumin absent; sugar absent; total amount in twenty-four hours, 320 c. c.; urea, 10.880 grm.; abundant epithelial, hyaline, and granular casts.

Uranalysis, April 1, 1891.—Reaction superacid; high color; specific gravity, 1.020; no albumin; epithelial and granular casts, uric-acid crystals.

Uranalysis, April 11, 1891.—Reaction mildly acid; color clear yellow; specific gravity, 1.022; no albumin; no casts found.

Uranalysis, April 15, 1891.—No albumin; no casts; total amount twenty-four hours, 992 c. c.; urea, 16.856.

CASE II.—Mr. B. C., aged seventy-one. Appetite poor, thirst constant; constipation; tongue coated, pale, and tremulous. Patellar reflexes absent; staggers with eyes closed; locomotion difficult; blood-vessels somewhat hardened.

Uranalysis, December 1, 1892.—Reaction neutral after standing; color reddish-yellow; specific gravity, 1.018; no albumin; total amount twenty-four hours, 1,120 c. c.; urea, 10.080; calcic oxalate crystals and hyaline casts.

CASE III.—Mr. A., aged sixty-eight. Suffering from great general weakness, loss of appetite, gastric distress, dyspnoea, left hydrothorax, and chronic diarrhoea.

Uranalysis, August 31, 1892.—Superacid, small sample; no albumin; granular and hyaline casts.

Uranalysis, September 9, 1892.—Reaction acid; color pale yellow; specific gravity, 1.015; no albumin; total amount twenty-four hours, 875 c. c.; urea, 25.00 grm.; uric-acid crystals, urate of ammonia, granular casts abundant.

CLASS V. CASE I.—Mr. J. H., aged about fifty-eight. Suffering from general weakness, poor appetite, constipation, insomnia, mental depression, and indefinite symptoms of chronic toxæmia from some cause.

Uranalysis, January 7, 1892.—Reaction faintly alkaline after standing; color pale yellow; specific gravity, 1.008; total amount twenty-four hours, 1,728 c. c.; total solids, 475 grains; urea, 12.046 grm.; no albumin; triple phosphate crystals; no casts.

Uranalysis, January 14, 1892.—Specific gravity, 1.006; no albumin; total amount twenty-four hours, 1,664 c. c.; urea, 13.312 grm.; total solids, 364 grains; microscopically, negative.

Uranalysis, January 24, 1892.—Specific gravity, 1.012; total amount twenty-four hours, 1,536 c. c.; total solids, 633 grains; urea, 10.752 grm.; no albumin; no casts.

I examined this patient's urine many times, but did not find albumin or casts. He improved greatly under the treatment that will be described by Dr. Rochester, as did indeed almost all the cases I report in this paper.

CASE II.—Mrs. P., widow, aged sixty. Symptoms: poor appetite with weight and burning in the epigastrium, flatulence very annoying. Bowels said to be regular, but abdominal palpation gives suspicion of fecal masses in colon. Tongue red with granular surface; skin loaded; pulse weak, small, and frequent.

Uranalysis, February 2, 1892.—Reaction moderately acid; high-colored; no sediment; specific gravity, 1.016; total amount twenty-four hours, 928 c. c.; total solids, 563 grains; urea, 14.920; no albumin; no sugar; microscopically, negative.

Uranalysis, February 8, 1892.—Reaction acid; color yellow; specific gravity, 1.010; no albumin; total amount twenty-four hours, 800 c. c.; urea, 6.00; total solids, 275 grains; microscopically, negative.

Uranalysis, February 17, 1892.—Specific gravity, 1.008; no albumin; total amount twenty-four hours, 1,152 c. c.; urea, 5.760 grm.; solids, 316 grains; microscopically, negative.

CASE III.—Mrs. B., widow, aged sixty. Complains of great nervousness and obstinate insomnia, which have gradually been increasing in severity for several months. Says she feels terribly depressed and would rather suffer pain than endure the nervous tension that she has, which does not seem to relax a moment. Complains of nothing else. Upon examination, I found her left ventricle weak, flabby, and dilated; pulse small and weak; skin dry and pale; extremities cold.

Uranalysis, May 25, 1893.—Reaction faintly acid; color, smoky, pale yellow; specific gravity, 1.006; no albumin; total amount in twenty-four hours, 1,280 c. c.; urea, 5.120. Microscopically, negative.

Uranalysis, June 5, 1893.—Total amount in twenty-four hours, 608 c. c.; urea, 11.55; specific gravity, 1.020; no albumin; no casts.

CASE IV.—Mr. J. W., aged thirty-six, well nourished; weight, one hundred and seventy pounds. Chief complaint, nausea and vomiting, especially in the morning; does not use alcohol immoderately; nausea lately has occurred immediately after every meal and nothing but vomiting relieves it. Some

days nausea continues without remission for many hours and becomes almost intolerable.

Uranalysis, April 4, 1893.—Reaction normally acid; color, clear yellow; specific gravity, 1.007; no albumin; no sugar; total amount in twenty-four hours, 2,560 c. c.; solids, 616 grains; urea, 10.240; microscopically, negative.

Uranalysis, April 9, 1893.—Specific gravity, 1.010; no albumin; volume in twenty-four hours, 2,016 c. c.; urea, 8.064; no casts.

Uranalysis, April 9, 1893.—Specific gravity, 1.010; no albumin; total amount in twenty-four hours, 2,016 c. c.; urea, 8.064; microscopically, negative.

Uranalysis, April 15, 1893.—Specific gravity, 1.005; no albumin; total amount in twenty-four hours, 2,128 c. c.; urea, 6.384; microscopically, negative. Many subsequent examinations of this patient's urine yielded results similar to the above.

CASE V.—Miss H., aged twenty-four; only serious illness was scarlatina when thirteen years old. Complains of gastric weight and distress after eating, with a good deal of gastric flatulency; some sour stomach; no pain. Has been constipated for years and is so now. Has some headache. Thinks all her trouble lies in her stomach and in her constipation. Circulation very poor; hands always cold and clammy.

Uranalysis, June 1, 1893.—Reaction neutral after standing; color, yellow; specific gravity, 1.008; albumin doubtful, perhaps faint trace; total amount in twenty-four hours, 1,152 c. c.; urea, 3.456; no casts.

Uranalysis, June 9, 1893.—Total amount, 416 c. c. in twenty-four hours; specific gravity, 1.027; albumin doubtful, perhaps very faint trace; urea, 12.064; no casts.

CLASS VI.—In this class I have no cases that I can catalogue positively, although I think many cases of renal insufficiency in pregnant women depend upon disturbance of the function of the kidney reflexly from the effect of the pregnant uterus upon its nerve supply. This matter has been exhaustively studied by Alexander Peyer (2), wherein he speaks of anuria of nervous origin, and describes the following case: "I treated a case sent to me by a colleague from the country, the patient being a very hysterical woman with a retroflexed uterus. Frequently the woman went for two or three days without passing a drop of urine and felt no desire to do so. Then the urine that she passed at a time would amount to about five or six ounces and had a specific gravity of 1.018. The urine became cloudy as soon as passed, owing to the presence of the uric-acid salts. The urine always showed traces of albumin. By replacing the uterus this functional neurosis of the kidneys disappeared."

Dr. R. Caspar (3), in a monogram upon this subject, says in substance that, just as in the case of the sweat glands, which, by the influence of special secretory nerve filaments, secrete independently of the circulation, so the kidney functionates independently of the rapidity or tardiness of its circulation. He thinks influences disturbing this special innervation bring about not only temporary abnormal function, but actual renal disease. Dr. Caspar thinks renal paralysis may occur reflexly from abnormal conditions of the uterus, ureter, bladder, prostate, and peritonæum, and from great depression with general enfeeblement of the nervous system. He cites many cases, among which is one of uræmia in a puerperal woman resulting in

death, in which case he made the diagnosis "reflex puerperal anuria and uræmia."

Anuria and oliguria of nervous origin have been noticed and studied by Benedikt, Denian, Charcot, Hermann, Cohnheim, and Uitzmann.

In glancing through the literature upon disorders of the kidney, I found several references touching upon the subject matter of this paper at one point or another, and may be allowed to summarize them here.

Coquet (4) presents a study of nephritis without albuminuria. He cites cases in which albuminuria was absent part of the time, others in which it was absent until just before death, and still others in which it was absent all the time. He does not regard albuminuria as diagnostic of the presence of Bright's disease, but thinks the toxicity of the urine is the surest criterion of that disease.

Chabrely (5) says albuminuria may be entirely absent in pronounced cases of nephritis, and in others is not an accurate index to the degree of renal alteration. On the other hand, Porter (6) considers the quantity of albumin in the urine to be always in direct proportion to the extent of degenerative change in the tubular epithelium of the kidney. Mesnard (7) cites several cases of undoubted Bright's disease in which albuminuria did not occur. In the diagnosis of renal insufficiency this author places great value upon the estimation of the toxicity of the urine, according to Bouchar's method of intravenous or hypodermic injection of the filtered urine in sufficient quantity to cause death in the animal experimented upon. Ordinarily for every kilogramme of the weight of a rabbit, fifty c. c. (one ounce and three quarters) of normal urine are necessary to produce lethal poisoning. Therefore, if more than this amount of urine is required to cause death, it is evident that the kidneys of the person from whom the urine is taken are not eliminating sufficient poison.

In references to acute manifestations of impaired renal elimination without the ordinary evidences of disease of the kidneys, Hare (8) reports, among several cases, one in the person of a man who, though in apparently perfect health, suffered from frequent attacks of severe headache, cold extremities, drowsiness, and nausea. During the attacks a very small amount of hyperlithuric urine was voided. The attacks could always be obviated by drinking freely of diuretic water when increased specific gravity of the urine was noted. Sir Andrew Clark (9) ascribes many nervous symptoms and a general condition of indisposition to renal impotence in which the urine is scanty, of low specific gravity, and deficient in urea, although no evidence of structural disease of the kidney exists.

Many observations of a like nature to the foregoing are to be found in the literature of this subject.

I am indebted to the kindness of Dr. Stockton for the privilege of reporting several of the cases in this paper; the others occurred in my own practice. I owe my thanks to Dr. Rochester for the case he so kindly furnished me.

From the foregoing imperfect though suggestive study we may draw the following conclusions:

1. From the standpoint of scientific internal medicine, no patient suffering from whatever ailment receives full

justice at our hands unless we examine his urine carefully.

2. Our examination of the urine often fails to throw light upon a case that repeated uranyses will afford.

3. The fact that albumin and casts are not found in the urine is not sufficient warrant for concluding that renal insufficiency does not exist.

4. Notably lowered elimination of urea by the kidneys exists in cases presenting no evidence of renal disease by superficial uranalysis.

5. The examination of the urine for the total urea and other solids voided in twenty-four hours is fully as important as the qualitative examination for albumin.

6. The microscope is indispensable in uranalysis.

7. Very valuable data for the application of therapeutic measures are obtained by repeated and painstaking uranalyses.

436 FRANKLIN STREET.

TREATMENT OF RENAL INSUFFICIENCY.

By DE LANCEY ROCHESTER, M. D.,

ADJUNCT PROFESSOR OF MEDICINE, MEDICAL DEPARTMENT,
UNIVERSITY OF BUFFALO;
ASSISTANT VISITING PHYSICIAN, BUFFALO GENERAL HOSPITAL.

THE treatment of renal insufficiency should depend upon the character of the insufficiency and the cause of the inefficient action of the kidneys.

The insufficiency may be one in which the total amount of excretion is diminished, one in which the amounts of the different constituents of the urine are altered in relation to each other, or one in which abnormal constituents are present.

The first class of cases—that in which the total amount of excretion, fluid and solid, is diminished, the amounts eliminated, however, bearing a proper relation to each other—is generally the result of an imperfect metabolism and not due to any especial diseased condition of the kidney. It is best treated by attention to the general metabolic processes, the use of exercise, baths, vigorous skin friction, attention to daily evacuations from the bowels, and the free use of diluents, particularly distilled water or one of the mild natural spring waters, such as the Bethesda, Poland, or Buffalo Lithia water.

The second and third classes that I have mentioned may be conveniently subdivided according to the scheme presented by Dr. Allen Jones, and I will follow his classi-

fication in the remarks that I may have to make as regards treatment, presenting one or two cases in each class illustrative of the plan of treatment suggested.

Cases of acute nephritis and certain cases of chronic nephritic degeneration of the parenchymatous and diffuse types would come under the heading of the first class—"those in which persistent and pronounced albuminuria is found together with renal casts." How shall we treat them? They are generally accompanied by œdema of various parts of the body, which is marked in proportion to the seriousness of kidney insufficiency; there is also generally well-marked anæmia. The indications are clear: Give the inflamed or degenerated organ as much rest as possible by relieving the blood pressure in its capillaries and by opening other avenues for elimination of the excrementitious matter that should under normal physiological conditions be passed out in the urine.

Nothing could be more wrong than to give diuretics under such conditions. Let me cite a case in point:

On August 7, 1892, W. F. T., a young man, consulted me, presenting the following history: In January, 1892, he had had diphtheria, from which he had recovered, but about a month afterward he had noticed some puffiness about his eyes; this had very gradually increased and spread, so that when he came to my office he had general œdema of the subcutaneous areolar tissue, ascites, and œdema of both lungs, headache, dizziness very marked, and tendency to constipation. There was no evidence, upon physical examination, of disease of the heart, but there was great tension of the pulse and some thickening of the arterial coats. Examination of the urine showed the following: Amount in twenty-four hours, 550 c. c.; color dark; transparency cloudy; reaction acid; specific gravity, 1.018; urea, 6 grammes; albumin abundant; sugar, none; microscope, amorphous urates; hyaline and a large number of small granular casts.

When this case came under my observation I had just read in one of the journals an article on the use of diuretin in just such cases with remarkably good results. Although I felt that the use of such a drug was contrary to a rational interpretation of the symptoms, nevertheless I determined to try it, because I had been so much impressed by the wonderful results reported. I put the patient to bed, put him on milk diet and the diuretin, gave four days' good trial, with the result that the urine steadily diminished in amount, the œdema steadily increased, and the headaches became almost unbearable. I then stopped that drug, determining that never again should I be tempted to act contrary to the dictates of reason in a matter of therapeutics. I continued to keep the patient in bed and kept up the milk diet, but I called upon his skin and his bowels to relieve his kidneys, with the most gratifying results. He was made to sweat by steam baths in bed given by means of the apparatus I show you here. The technique of such a bath is simple, so that the bath can readily be given in a private house.

The patient is placed entirely nude between blankets in bed and covered with two extra blankets; the boiler B is a little more than half filled with water, which is brought to the boiling point; the cover C is then firmly fastened on and the nozzle D is introduced under the bed-covering, so that the patient becomes enveloped in steam; this bath is kept up for half an hour to an hour, according to the effect produced. These steamers may be procured from Walbridge & Co., in this city, for three dollars apiece. These baths were given every day for a week or two; then the intervals between the baths were length-

ened until two a week sufficed to keep him in good condition. At the same time that the sweats were instituted copious evacuations from the bowels were produced by means of calomel, fol-

FIG. 1.—A is a gas or oil stove; B is a copper or tin boiler; C is a close-fitting cover for the same, out of the top of which projects a long nozzle or nose-piece, D.

lowed by the free use of Epsom salts. Patients of this class not infrequently vomit almost anything given them by mouth, but I have rarely found one who could not take Epsom salts given according to the following plan: Fifty or 60 c.c. of the saturated solution of the salts is given without dilution every two hours until watery movements begin.

After free catharsis had been once produced in this manner, one or two daily evacuations were kept up by one daily dose of the saturated solution of Epsom salts. After a few days of this treatment, together with dry cupping of the chest to relieve the oedema and congestion of the lungs, the ascites and anasarca rapidly subsided. Tinctura ferri chloridi in 150 c.c. doses was added to the medication, and vigorous massage followed each steam bath.

On October 4, 1892—two months after treatment had been begun—the analysis of urine was as follows: Amount in twenty-four hours, 2,400 c.c.; color, yellow; transparency, slightly cloudy; reaction, acid; specific gravity, 1.012; urea, 16.47 grammes; albumin, abundant; sugar, none; microscope, granular and hyaline casts.

Three months later—five months after treatment had been begun—there was no material difference in the analysis from that just given. The patient was feeling much better, the oedema pulmonum had not reappeared, there was no fluid in the abdomen, and only slight oedema of the legs and occasionally puffiness of the eyelids.

In Class II, those having albuminuria and renal casts inconstantly present, I will present two cases for your consideration:

CASE I.—Mrs. G. P., aged sixty-five. Attacks of dizziness, nausea, weakness, shortness of breath, and persistent watery diarrhoea, with occasional blood and mucus. No evidence of lesion of brain or spinal cord; lungs slightly emphysematous in patches; heart muscle weakened and left ventricle slightly dilated; no evidence of valvular lesion. Examination of urine March 16, 1893: Amount, 400 c.c.; color, brownish-red, cloudy; reaction, hyperacid; specific gravity, 1.015; urea, six grammes; albumin, none; sugar, none; microscope, epithelium of various kinds, several small granular casts.

I wish to call especial attention to this urine, because it would pass the ordinary insurance examination, the microscope not being used when there is no albumin or sugar present, and the specific gravity is 1.015. But the quantitative examination of the total amount passed in the twenty-four hours shows immediately that the cause of her dizziness, nausea, shortness of breath, weakness, and diarrhoea is the poison locked up in her system that should be carried off in the form of urea.

She was given daily hot-air baths, plain digestive diet, a little strophanthus and strychnine (in spite of her diarrhoea),

and Bethesda water to drink. In two weeks the analysis of her urine showed: Amount, 750 c.c.; color, yellowish red; reaction, hyperacid; specific gravity, 1.017; urea, 25 grammes; albumin, trace; sugar, none; microscope, considerable columnar epithelium, granular and epithelial casts.

The diarrhoea had ceased without the administration of any diarrhoea mixture; the nausea had disappeared, and she was hungry and digested her food well; the dizziness, shortness of breath, and general muscular weakness had markedly diminished, though still present. The patient felt so much better that she stopped the hot-air baths, but takes a very hot tub-bath once or twice a week and keeps in very fair shape.

How to give a hot-air bath at home is, not infrequently, considered a matter of great difficulty, whereas it really is very simple. It can be given in one of two ways. If the patient is strong enough to stand it, it can be given in a chair. A firm cane-seated chair is chosen; over the cane seat a board about six inches wide is placed; the patient, in a nude condition, sits upon this board, a blanket under his feet; another blanket is then thrown around the patient and the chair, so that only the patient's head remains outside, the blanket being gathered around the neck and fastened at the back, the laps folding one over the other down the outside of the back of the chair to the floor; over the blanket a rubber sheet is fastened in the same manner. An alcohol lamp, resting on a tray, is now introduced from behind and placed under the chair and lighted, the blanket and rubber sheet being closed at the back. Cold cloths are kept on the patient's head during the bath. A half hour generally produces copious sweating.

Another method of giving the hot-air bath is by means of the apparatus here shown. The patient lies in bed as

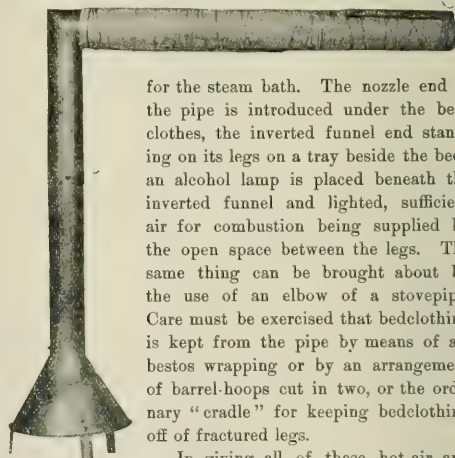

FIG. 2.

for the steam bath. The nozzle end of the pipe is introduced under the bed-clothes, the inverted funnel end standing on its legs on a tray beside the bed; an alcohol lamp is placed beneath the inverted funnel and lighted, sufficient air for combustion being supplied by the open space between the legs. The same thing can be brought about by the use of an elbow of a stovepipe. Care must be exercised that bedclothing is kept from the pipe by means of asbestos wrapping or by an arrangement of barrel-hoops cut in two, or the ordinary "cradle" for keeping bedclothing off of fractured legs.

In giving all of these hot-air and steam baths, the comfort of the patient is materially increased if cloths wrung out in cold water are kept upon the head. A copious draught of hot water, with a little whisky in it, often starts the sweat when it seems slow in coming. The regular use of the whisky, however, is generally not to be recommended in these cases.

CASE II.—Mrs. F. C. P., aged seventy-three, was seen March 2, 1893. She was sitting up in bed gasping for breath and suffering from repeated attacks of angina pectoris which recurred at constantly diminishing intervals. She was markedly constipated, her head ached violently, and she vomited whatever she tried to eat. Her family was grouped about her in expectation of her immediate demise. Examination showed a spare, pale woman with thickened and contracted arteries, oedema of lower extremities, congestion and oedema of both lungs, aortic obstruction and insufficiency, dilated left ventricle, and occasional safety valve yielding of the tricuspid valve. The amount of urine passed in twenty-four hours was stated as less than 180 c. c., but, as the exact amount was not known, the urea was not estimated. It contained albumin and epithelial and granular casts.

I ordered for her a hot footbath given in bed every two hours; dry cupping of the chest in front and behind; the use of Bethesda water as a drink; and strophanthus, strychnine, and caffeine as medication; a diet of peptonized milk; opening of the bowels with calomel and Epsom salts.

In two days the urine had increased to 1,000 c. c., containing twenty-four grammes of urea; albumin and granular casts still present.

The footbaths were discontinued and a steam bath given every day. Under this treatment she steadily improved—so much so that she thought best to discontinue treatment for a while, when a return of former symptoms warned her to begin again. Her urine was examined every week for eight weeks. At the time she stopped treatment the amount of urine dropped to 713 c. c. and the urea to 8.556 grammes. Upon resuming treatment, the urine rose in amount to 1,200 c. c. and the urea to 21.6 grammes. The last two examinations have revealed neither albumin nor casts present, and the old lady considers herself well, but she keeps up her steam baths once or twice a week.

I will briefly relate three more cases, one in Class IV and two in Class V, as these classes are the most frequently overlooked:

The case in Class IV—those showing renal casts without albumin—is Mrs. B., aged thirty-four. She complained of insomnia, restlessness, violent headache, nausea and vomiting, marked constipation, intractable cough, and cardiac palpitation. Without relating the examination of the case in detail, let it suffice to state that the analysis of urine was: Amount, 100 c. c.; color, brownish-black, cloudy; reaction, hyperacid; specific gravity, 1.025; urea, 2 grammes; albumin, none; sugar, none; microscope, epithelial casts.

She was given calomel and Epsom salts, as related above; a hot footbath in bed every three hours; distilled water to drink; beef peptonoids for food for a day; and then a gradually increased diet. In five days, on March 10th, the urine analysis was as follows: Amount, 1,920 c. c.; color, greenish-yellow; reaction, hyperacid; specific gravity, 1.006; urea, 15.86 grammes; albumin, none; sugar, none; microscope, epithelium in great amount; granular epithelial casts.

In a week she felt so much better that she thought she had no further use for a doctor, and I have not heard from her since.

Of Class V—those showing neither albumin nor casts present, but revealing a markedly lowered elimination of urea and other solids—the two cases that I have to relate are of especial interest in that the first is that of a young woman who was markedly anemic and hysterical, and the second is that of an old lady who suffered from purpura hæmorrhagica:

The urine has been examined fifteen times in the first case and eight times in the second, without revealing albumin or casts at any of the examinations. The first case, besides steam baths and massage and distilled water to drink, has received iron, cod liver oil, strychnine, and strophanthus. I will not detail all the examinations, but will give you the results of the first and the last, stating also that the young woman was unable to walk without assistance and fainted when she attempted to get up, and is now up and out every day, walking about and gaining in weight and strength.

The first urine analysis was as follows: February 18, 1893. Amount, 370 c. c.; color, yellow; reaction, hyperacid; specific gravity, 1.024; urea, 11.5 grammes; albumin, none; sugar, none; microscope, negative.

The last analysis is as follows: May 22, 1893. Amount, 1,800 c. c.; color, reddish-yellow; reaction, acid; specific gravity, 1.023; urea, 45 grammes; albumin, none; sugar, none; microscope, a few epithelia; amorphous urates.

I was called to the second case because of a purpuric eruption which had appeared on the leg and foot. The history was one of a lady, about sixty years of age, who had always enjoyed pretty good health, save that she had had for a number of years a monthly hæmorrhage from the rectum and occasional attacks of diarrhoea accompanied by mucous discharge. She had lately noticed some dizziness and general muscular weakness.

Under treatment there has not been much change in the character of the urine analysis, the amount of urine varying from 960 c. c. to 2,160 c. c., and the urea from 2 to 4 grammes. But, by calling the skin into activity so that the urea may be carried off in that way, all the unpleasant symptoms have disappeared and remain in abeyance, the patient taking two hot tub baths weekly. She now walks about and enjoys life without fear of faintness, dizziness, or diarrhoea.

Evidently this is a case of contracted kidney, the degeneration of which is beyond recovery, and consequently it is all the more important to keep up the hot baths and prevent reaccumulation in the system of katabolic materials that should be excreted.

The conclusions to be drawn from these cases as regards treatment are:

1. We should not try to stimulate into activity an organ that is inflamed or degenerated, by the use of drugs that excite functional activity of such organ; in the case of the kidney we should rarely, if ever, have recourse to stimulating diuretics, or to diuretics which, like digitalis, act by increasing the arterial pressure, until we have relieved the venous congestion by diaphoresis or catharsis, or both.

2. Attention to diet is of the utmost importance in these cases.

3. In order that the materials to be excreted by the kidney may come to that organ in the most unirritating form, the metabolic processes should be carried to completion; this is to be accomplished by regular systematic exercise, which is to be obtained by massage when active exercise is not advisable, by inhalations of pure oxygen gas when it is evident that sufficient oxygen is not obtained from the air, and by the dilution of the katabolic materials by drinking large amounts of distilled water or one of the mildly alkaline waters, such as Bethesda, Poland, or Buffalo Lithia water.

4. The anæmia that accompanies these cases should be met by the use of oxygen and iron.

5. As the symptoms indicative of this condition are the result of toxæmia which depends upon the non-elimination from the body of certain katabolic materials that should normally be carried off through the kidneys, and as these organs are in such condition that they can not do their work, all other avenues of elimination should be opened up for the escape of these poisons. This is to be brought about by exciting the activity of the skin by means of hot-air or steam baths accompanied and followed by vigorous massage; keeping the bowels open by means of salines and by washing away the contents of the colon, thus keeping the mucous membrane in a proper condition for excretion, with copious enemata of slightly alkaline water, occasionally followed by a high enema of 500 or 600 c.c. of pure olive oil, as suggested by Fleiner (*Berliner klin. Wochenschr.*, 1893, Nos. 3 and 4).

CASES IN INTESTINAL SURGERY.

By APMORGAN VANCE, M. D.,
LOUISVILLE, KY.

CASE I.—*Strangulated Femoral Hernia; Resection of the Gut at the End of Eleven Days; End-to-End Anastomosis; Wölfler's Method Modified; Recovery.*—On January 30, 1893, I was called by her physician to see K. G., aged thirty-three, domestic, who gave the following history:

Eleven days previously she was taken sick suddenly with vomiting followed by purging. Purging ceased early on the first day; the vomiting continued until seen by the writer.

It was evident that the extreme modesty of the patient had prevented the physician attending from discovering the cause of the trouble, which upon closer investigation proved to be a strangulated femoral hernia of the left side.

The patient gave evidence of extreme exhaustion, the pulse being 150; the temperature, according to the physician, subnormal. No history of the hernia antedating the present illness could be obtained, and the patient had never been seriously sick before, having suffered occasionally from "bilious attacks" of short duration.

Nitroglycerin, one one-hundredth of a grain, was administered hypodermically at once, and the patient removed in a rolling chair to the John N. Norton Memorial Infirmary, only a short distance from her residence; and after slight preparation,

FIG. 1.—Showing sphacelous portion.

at 11.30 P. M., the operation for the relief of her condition was begun, Dr. J. W. Guest administering ether, Dr. H. E. Tuley and Dr. C. G. Lucas assisting.

Upon exposure and shaving of the pudendum, the tumor was

found to be of about the size of a hen's egg. The sac was exposed and opened and about half an ounce of very dark-colored fluid evacuated, and the blackened intestine lifted out of the sac. The sac was much thicker than is ordinarily found in a recent hernia, so it is probable that the hernia had existed without the patient's knowledge.

The very tight constriction was relieved by the hernia knife, and, after thorough irrigation with sterilized filtered water, the intestine was carefully drawn out, when one large perforation discharging fecal matter was drawn into view, the intestine being sphacelous in the line of constriction, which included a large portion of the convexity, the mesenteric border not being involved.

This line of slough was fully four inches in length. Resection was immediately determined upon, and an end-to-end anastomosis decided to be best suited to the condition. The assistants each making digital compression (Fig. 2) well on either side of the strangulated portion, nine inches were quickly removed with scissors, the incisions being extended between the vessels down into the mesentery, a silk ligature being ap-

FIG. 2.—Showing excised portion. (After Wyeth.)

plied and the whole removed. These incisions approached each other so nearly that the part controlled by the ligature was not more than an inch in width.

There was no hæmorrhage and the suturing was rapidly done as follows:

By a continued fine catgut suture the mesenteric borders were closely approximated; with the same size catgut, which was No. 0, an interrupted suture was passed from the inside through the entire thickness of the intestinal wall, coming out at a corresponding point of the opposing gut to be approximated (Fig. 3).

FIG. 3.—Modification of Wölfler's method. Showing stitches inside.

The part of the intestine above the constriction being greatly dilated and that below being collapsed, made the approximation more difficult, but the result obtained was good.

The first stitch was taken through the mesenteric junctions. This method of suturing was continued on either side of this point just as far as could be accomplished from the inside (Figs. 4 and 5); the remaining third of the circumference was

carefully closed by interrupted Lembert sutures. To make the closure doubly sure, a continued Lembert suture was commenced on one side at the apex of the mesenteric angle, and continued from this point around the gut to a corresponding

FIG. 4.—*b, b*, mesenteric border of gut, sutures on inner side; *a, a, a*, continuous Lembert suture. (After Wyeth.)

point on the other side. By this means there was no fresh surface left uncovered by peritonæum.

During the whole procedure the parts were frequently douché, and every care taken to prevent infection of the cavity.

With some little difficulty the sutured part was returned to the abdomen, the sac being removed high up, and deep approxi-

FIG. 5.—After Wyeth.

mation sutures applied to the canal. The wound was closed with silk worm gut, with a gauze drain in the lower angle.

The patient's condition at this time was better than when first seen, the pulse being 135 when the operation was commenced, falling to 120 before its completion. The operation was begun two hours after the patient was first seen, and there was certainly a very decided effect from the nitroglycerin, the operation occupying fifty-three minutes.

FIG. 6.—Showing completed operation. (After Wyeth.)

The fact that the patient had continued so long without nourishment rendered her chances of recovery much less, as an element of exhaustion had to be considered and combated.

The patient was got to bed at 12.30 A. M., and from this time till 6 A. M. she vomited six times a greenish, watery fluid. Pulse ranged between 92 and 140. Morphine, a quarter of a grain with atropine, was given at 1 A. M., and morphine alone at 6 A. M. She slept some after two o'clock.

During the day she was restless and hypodermics of morphine were given at noon and at 5 P. M.

The patient received and retained half an ounce of wine and Apollinaris water given every hour during the forenoon, and wine and beef peptonoids in the afternoon.

A rectal tube was introduced at 8 and 11 P. M. and considerable gas passed.

The pulse gradually increased in frequency from 108 at 1 P. M. to 132 at 5 P. M.

Digitaine was given hypodermically at 9 P. M. and 3 A. M.

The temperature in the evening was 101.6° per rectum.

The patient slept well all the night of the 31st.

February 1st.—During the day the pulse was not above 100; the patient was comfortable except cramping pains in the abdomen. The dressing was changed and hypodermics of morphine were given at 3.30 P. M. Wine and beef peptonoids given every two hours. At seven o'clock on the morning of the third day she was given an enema of water, one pint, which was returned slightly colored. At 11 A. M. an enema of Epsom salts, glycerin, and water was given, a medium-sized, partly-formed movement resulting. She passed considerable gas and complained of gripping pains in the abdomen. She vomited once a large quantity of light green fluid.

She had four stools during the afternoon and night. Pulse through the day not above 112. Maximum temperature, 99.8°.

She slept fairly well during the night.

3d.—She was restless and complained of pain in the bowels, for which a hypodermic of morphine was given at 5 A. M.

During the day she vomited eight times; only four ounces of peptonized milk were retained. The vomiting was not controlled by sinapisms over the epigastrium or by listerine by the mouth.

The pulse ranged between 112 and 124 during the day. Temperature, 101.4°. Abdomen flat; slight tumefaction over the transverse colon.

During the following day she vomited eleven times, apparently without effort, very little nausea being present, the vomited matter consisting of greenish fluid and at times curdled milk.

She was given aromatic spirits of ammonia, calomel, and morphine. Pulse not over 96. Temperature, 99°.

During the night she vomited nine times, sleeping but little. Maximum pulse, 100; one small, thin stool containing particles of undigested milk.

5th.—During the day she vomited but twice, a good effect seeming to be derived from the administration of oxalate of cerium.

Hypodermic injections of whisky were given every three hours, beginning at 7.30 A. M., continued until 11 A. M. on the morning of the seventh day.

6th.—She was unable to take more than one drachm of milk at a time, but vomited only three times.

The wound was dressed at 8.30 A. M. and the stitches removed. A slight discharge of serum at the lower angle of the wound was noted, which continued through the day.

Wine of cocaine was given in teaspoonful doses with half an ounce of beef peptonoids every two hours. The maximum pulse was 118, the rise being caused by the entrance of a stranger into the room.

The patient's general condition at this time was excellent. She continued to improve until the tenth day, when she had four large, thin stools, which were controlled by paregoric and bismuth subnitrate.

The vomiting had ceased, pulse and temperature were normal, the general condition was good. A slight serous discharge continued from the wound.

The careful nursing of this case under the efficient supervision of Miss Gillett, assistant superintendent of the infirmary, is in a large measure to be credited with its successful termination.

In every case of emergency of this kind a rapid decision is necessary as to what is best, and this depends entirely upon the condition of the patient. To my mind only one of two procedures is legitimate: If the patient is *in extremis* and plainly unable to withstand a prolonged operation, the production of an artificial anus is the operation; but if, in the estimation of the operator, the condition justifies it, even to straining a point, the patient should have the benefit of the doubt, and a complete operation be performed as in this case.

Either terminal anastomosis by absorbable rings or plates is decidedly less feasible or surgical, as a celiotomy is made necessary from inability to return the repaired intestine through the small hernial opening.

The risk in celiotomy is in septicizing the cavity, which is rendered *nil* by working entirely through a slightly enlarged hernial opening.

CASE II.—*Resection of the Small Intestine for Gangrenous Hernia; Wölfler's Method Modified; Death.*—On July 18, 1892, I was called to see Miss X., aged twenty-five, who gave the following history: She had been the subject of right femoral hernia for three years, having been treated during this time by an irregular "specialist," who used a so-called "electric truss," which she wore for two years.

Some weeks before she was seen by the writer, as a cure of the rupture had been accomplished, according to the "specialist's" statement, the truss was discontinued. Eight days before the writer was called the hernia had again descended and become incarcerated, and, after much manipulation by the same "specialist" under chloroform, it was supposed to have been again reduced.

During this period vomiting was constant, and under the family physician rectal alimentation was used, the patient remaining in bed.

The tumor returned at the end of this period, upon the patient leaving the recumbent position, and, when examined, the surrounding parts were found to be very boggy, and evidences of active inflammation were present. The patient was evidently in a condition of marked sepsis.

Immediate operation was proposed and consented to. When the sac was reached it was found gangrenous and ruptured, large quantities of fluid fecal matter having escaped into the tissues about.

A small knuckle of the small intestine was found completely gangrenous and ruptured. Primary resection was done just as described in the foregoing case, four inches only of the intestine being removed, every care being taken to insure an aseptic condition before returning the gut to the cavity, the sac being tied off very high up, and the external wound packed with iodoform gauze.

The patient bore the operation, which lasted fifty minutes, without any evidence that her condition had been made worse; she continued to do well for forty-eight hours, when active delirium and other evidences of septic poisoning were marked, and death followed in sixty-two hours after the operation. There were no evidences whatever of peritonitis, three large evacuations through the bowel having taken place, the abdomen remaining perfectly flat.

So far as could be determined, the septicæmia was due to the condition of the external wound. No post-mortem was allowed, and we have only the symptoms to judge from.

CASE III.—*Abdominal Gunshot Wound; One Mesenteric and Four Intestinal Perforations; Celiotomy; Recovery.*—On February 7, 1893, I was called to see H. F., aged twenty-nine, who a half hour before had received a pistol-shot wound of the abdomen, the ball entering in a line with and five inches to the left of the umbilicus. The man was found where he had fallen after running two squares, with marked evidences of shock, face pallid, pulse barely perceptible at the wrist; temperature not taken.

A hypodermic injection of nitroglycerin, one one-hundredth of a grain, was given, and the patient removed carefully and rapidly fully a mile to the John N. Norton Memorial Infirmary, where, with the efficient assistance of Dr. J. W. Guest, Dr. H. E. Tuley, and Dr. C. G. Lucas, and after as careful preparation as the circumstances of the case would allow, the cavity was opened in the median line between the umbilicus and pubes, no attention being given to the bullet wound. The ileum was brought out and carefully read, no more than six inches being exposed at a time during this process.

Four perforations—two of entrance and two of exit—were closed with fine catgut, as was also a large wound of the mesenteric border, which exposed the mucosa. Careful search was made for any other injuries, but none were discovered. The cavity was then thoroughly irrigated and cleansed of the extravasated blood and fecal matter, the wound being closed with silk worm gut, a glass drainage-tube being carried well into the pelvis at the lower angle of the wound. The method of suturing was by the continued Lambert suture, which was rendered doubly secure by a resuturing with the same piece of catgut, the two ends being then tied together.

Either was the anesthetic used, and the patient vomited large quantities of undigested food, this necessarily prolonging the operation, which lasted fifty minutes.

The patient was put to bed comparatively in good condition, and his recovery has been uninterrupted, the only complication which has arisen being the suppuration of the track of the bullet in the abdominal wall, and at the end of the second week a slight rise of temperature due to an infection at the site of the drainage-tube.

The drainage tube was removed at the end of forty-eight hours, it having been demonstrated, from the amount of bloody serum aspirated, that its use was a wise precaution.

At the end of three weeks the patient is up and walking about the ward in excellent condition, appetite and digestion normal, giving evidence of having lost very little of his strength. The bowels seem to be undisturbed in their function, castor oil having been administered at the end of fourteen days, evacuations each alternate day being maintained prior to this by enemata.

The favorable outcome in this case is due to the fact that the bullet ranged transversely and evidently entered the abdominal wall on the opposite side at a point nearly corresponding to the point of entrance. This was not demonstrated, however, by its location. The direction of the bullet was changed by its having struck a trousers button in its passage through the clothing, thus being deflected from its primary course, which was directly backward.

This is the fourth case of abdominal gunshot wound operated on by the writer, the first patient having eight wounds of the ileum, living four days, the post mortem showing that death occurred from a wound of the ureter.

The second patient had eight wounds of the ileum and one of the fundus of the bladder, living three days, dying of sepsis due to infiltration of urine from the wound of exit in the bladder, which was undiscovered and must have been near the neck, as an abscess appeared in Scarpa's space before death.

The third had four wounds of the ileum, death at the end of thirty hours, the post-mortem proving death to have occurred from hæmorrhage into the bowel.

In all of these cases the wounds were from a pistol shot, the bullet being of .32 caliber.

The experience of the writer proves that success is due to the early period in which the patient is seen after the receipt of the injury, and from the fact that the bullet fails to injure the extraperitoneal and other abdominal viscera. After the patient has stood the necessary work to repair the intestines, additional exploration adds so greatly to the shock and to the time of the operation that a fatal outcome is almost certain.

The possibility of forestalling sepsis from the absorption of faecal matter is just in proportion to the time elapsing between the injury and the operation. This fact alone should admonish the surgeon to be always ready for such emergencies, that no time be lost. Another momentous factor in this connection is the necessity of the careful handling of the patient, that no unnecessary movement on his part shall increase faecal extravasation.

NOTE.—I am indebted to Dr. Henry E. Tuley for the original drawings from which Dr. Macdonald has made those used in the illustrations.

EYE TUBERCULOSIS

AND ANTITUBERCULAR INOCULATION IN THE RABBIT.*

By E. L. TRUDEAU, M. D.,

SARANAC LAKE, N. Y.

GENTLEMEN: At the last meeting of this association I presented a paper on the Treatment of Experimental Tuberculosis, illustrating the influence of such treatment on eye tuberculosis in the rabbit by photographs and living animals. The two last conclusions reached were as follows:

"Experimental tuberculosis in the rabbit's eye can be cured by such injections. The permanency of this cure has not yet been established."

A more extended experience has shown me that the cure of inoculation tuberculosis in the rabbit's eye by this method is by no means always a constant result or one which can be brought about invariably at will. I have failed often where I had every reason to expect success, and I have succeeded where I had no special reason to hope for a favorable result. This inconstancy in results may be explained by the great difficulty of controlling the relation existing between all the factors involved in the problem, such as the virulence of the bacilli injected, their number, the virulence of the microbes from which the tuberculin was made, and the degree of individual

resistance possessed by each animal. Cures do occur, however, and appear to have a certain degree of permanence, as the two animals I now show you illustrate. These rabbits were inoculated in the eye with cultures of tubercle bacilli of human origin more than a year ago. The eye of the untreated control is cheesy and atrophied. That of the treated animal shows but the fibrous evidence of the inflammatory changes of which it has been the seat; the sight is unimpaired, the cornea clear, the inoculation wound a mere corneal scar; the iris, dilated and showing on its surface small grayish fibrous specks at the site of the once evident miliary tubercles, is still adherent to the lens by fibrous bands, while the vascularity of the eye is normal. The present appearance has remained unchanged for six months.

Hitherto the tubercle bacillus has always been considered as a pathogenic microbe having but one source and possessed of a very constant degree of virulence. More recent researches by Muffici, Koch, Metchnikoff, Courmont and Dor, and Loeb have taught us that the virulence of this germ varies greatly and that there are two distinct races of tubercle bacilli—the mammalian and the avian. Loeb's experiments made in Koch's laboratory demonstrated that bacilli cultivated uninterruptedly for nine years and having descended from the original cultures used by Koch in his first experiments, and which then killed both guinea-pigs and rabbits within six to ten weeks, were no longer pathogenic for rabbits and but slightly so for guinea-pigs. Principally through the labors of the above-mentioned investigators it has also become known that the avian tubercle bacillus is apparently a race by itself and that it presents certain quite constant cultural and pathogenic peculiarities not observed in the microbe originally discovered, studied, and described by Koch. Whether these variations have merely been acquired by Koch's bacillus as the result of a long parasitic life history in the organism of birds, or whether they indicate a permanent difference of race, is still a disputed point; as yet, however, it has been found impossible by laboratory and inoculation experiments to show that either variety of these germs can be transformed into the other. In 1890 I presented and described before this association cultures of the tubercle bacillus which were not pathogenic for guinea-pigs and which showed marked cultural variations from the standard. The original source of these bacillary growths was somewhat doubtful, as they had been brought from Europe, and I supposed them to have become attenuated while under cultivation. In the light of recently acquired facts, however, it is quite evident that these attenuated cultures were bird tuberculosis, and the description then given will answer very well for the avian microbe as we now know it. In growing this variety of the tubercle bacillus from the lesions of tubercular birds, not only have I been able to confirm many of the observations made by Muffici, Koch, and the French experimenters, but I have been struck as well with two marked peculiarities which I have not seen described: 1. The ease with which the chicken bacillus adapts itself to a saprophytic existence, which is in strong contrast to the well-known difficulty of obtaining first growths of

* Remarks made before the Association of American Physicians at its eighth annual meeting.

Koch's bacillus in artificial media, for the avian microbe grows readily direct from the lesions of birds in most of the media in use, whether solid or fluid. 2. The strong anaerobic attribute possessed by the bird bacillus, which enables it to thrive readily within and beneath fluid media as well as on the surface, while the human microbe grows only when floated on the surface of liquids and in constant contact with oxygen, and develops almost imperceptibly or not at all when immersed. The *human bacillus* has been found by all observers to be about harmless for birds; though in rare instances intraperitoneal inoculations may cause an eruption of tubercle in these animals, intraperitoneal reinoculations of this tubercle prove negative and the animals remain healthy. The *avian bacillus*, when fresh from the lesions of birds or when cultivated but a short time in artificial media, is about harmless for dogs and guinea-pigs. Rabbits are, however, more susceptible to it, and die readily from intravenous, intraperitoneal, and intrathoracic injections of not excessive amounts of these cultures. On autopsy, they may either show extensive generalized tubercular lesions or they may present no evidence of tubercle in any organ, but an extreme emaciation only, as if they had died of chronic septic intoxication. When a small amount—0.05 to 0.25—of liquid culture grown a month direct from the chicken is injected under the skin, the animal generally recovers; an abscess is formed at the site of the inoculation which tends slowly to soften and become diffuse, and, finally, if the animal survives, disappears almost entirely. This brings us to the subject of preventive inoculation.

Antitubercular inoculation was first tried by Falk in 1883, and all attempts in this direction have resulted until recently in but an unbroken record of failures. In 1890 I added my name to the list of those who found it impossible to produce immunity in animals by this method. In 1890 Martin and Grancher and Courmont and Dor claimed to have produced in rabbits a certain degree of immunity by previous inoculation after Pasteur's hydrophobia method of avian tubercle bacilli of graded and increasing virulence. These vaccinations were, however, frequently fatal to the animals, and the immunity obtained was but slight. Richet and Héricourt have since claimed to produce complete immunity in dogs by intravenous inoculations of bird tubercle bacilli. These experimenters found that though harmless to the dog when first derived from the chicken, bird bacilli, by long cultivation in liquid media, become pathogenic for this animal, and by thus grading the virulence of the injections complete immunity against any form of tubercular infection was produced in the dog. As yet these striking results have not been confirmed. The animals which I now present to you illustrate an attempt I have made along the same line to produce immunity in the rabbit. Cultures grown directly from the chicken's lesions in bouillon for first five weeks, then six months, were twice injected subcutaneously at intervals of twenty-one days in doses of 0.025 and 0.05, and a third injection of a still older culture was occasionally given. About one in four of the rabbits died within three months, profoundly emaciated, but without any visible tubercular

lesions. The remaining animals recovered and were apparently in good health when, together with an equal number of controls, they were inoculated in the anterior chamber of the eye with cultures of Koch's bacillus derived from the tuberculous lesions of the rabbit and cultivated about three months on glycerin-agar. The results of these inoculations present many points of interest. In the controls, as is usually the case, if the operation has been done carefully and aseptically and with a moderate amount of dilute virus, two days after the introduction of the virulent material in the eye little or no irritation is observed, and little is to be noticed for two weeks, when a steadily increasing vascularity manifests itself, small tubercles appear on the iris which gradually coalesce and become cheesy, intense iritis and general inflammation of the structures of the eye develop, the inoculation wound becomes cheesy, and in six to eight weeks the eye is more or less completely destroyed and the inflammation begins to subside. The disease, however, remains generally localized in the eye for many months, and even permanently. In the vaccinated animals, on the contrary, the introduction of the virulent bacilli at once gives rise to a marked degree of irritation. On the second day the vessels of the conjunctiva are tortuous and enlarged, whitish specks of fibrinous-looking exudation appear in the iris and in the anterior chamber, and more or less intense iritis supervenes, but at the end of the second to the third week, when the eyes of the controls begin to show progressive and steadily increasing evidence of inflammatory reaction, the irritation in those of the vaccinated animals begins slowly to subside and the eyes to mend. The vascularity is less, the whitish spots of fibrinous material appear smaller, the structures of the eye become clearer, the inoculation wound is but a bluish, fibrous scar, until in from six to twelve weeks in successful cases all irritation has disappeared and the eyes present, as in the animals I now show you, but the fibrous evidence of the traumatism and the inflammatory processes which have been set up by the inoculation. In all the controls, as you see, the inoculation wound is cheesy and the cornea and iris are more or less destroyed by tubercle and cheesy areas.

Some of the protected animals slowly relapse, and the one I now show you has small tubercles growing on the iris; but even in such eyes the entire absence of caseation is noticeable and the disease progresses almost imperceptibly. I have repeated this experiment on three sets of rabbits with about the same results each time. The vaccinations as practiced are of themselves, in some instances, fatal, but the fact remains that where recovery takes place a marked degree of immunity has been acquired. I do not lay any claim, therefore, to have produced a complete or permanent immunity by a safe method, but it seems to me that these eyes constitute a scientific demonstration of the fact that in rabbits preventive inoculation of bird tubercle bacilli can retard and even abort an otherwise progressive localized tubercular process so completely as to prevent destruction of the tissues threatened, and that the future study of antitubercular inoculation may not be as entirely hopeless as it has until recently appeared.

DIPHTHERIA.*

By G. E. CRAWFORD, M. D.,

VISITING PHYSICIAN TO ST. LUKE'S HOSPITAL, CEDAR RAPIDS, IOWA.

My subject is a commonplace one, but, owing to its universal and increasing prevalence and great mortality, there is probably no subject in the whole realm of medicine of more vital interest to the general practitioner, as well as to his patrons, than that of diphtheria.

Diphtheria has justly become the dread and terror of the home. It is no respecter of caste, but visits alike the palace and the hovel, and no domestic circle is safe from its fatal ravages.

I will not presume to trespass upon your time with any description of this disease, so familiar to you all; nor do I expect to bring to you anything new or novel upon this familiar topic. But, from the very beginning of my professional career having had to pass through the trying ordeal of malignant epidemics of this most malignant disease incidental to our climate, and thus being compelled to treat a larger number of cases perhaps than falls to the lot of most practitioners, I purpose rather to give you the *résumé* of twenty years' conscientious study and observation, more especially upon the therapeutic indications.

That diphtheria is a contagious and infectious disease no one any longer doubts, though the profession was a little slow in acting on its belief in this matter. The latest investigations seem to verify the opinion that the Klebs-Loeffler bacillus is essentially the specific cause of diphtheria; that the ptomaines or toxalbumins resulting from the development of these organisms are the chemical poison which produces the profound toxæmia of the disease and the paralytic tendencies and manifestations. Brieger and Fränkel have isolated this toxalbumin, and with it demonstrated upon animals all the paralytic phenomena of diphtheria, as well as the albuminuria and nephritis. Associated with the Klebs-Loeffler bacillus in diphtheria are several other pathogenic bacteria, and just what more or less important rôle they play in the cause and complications of the disease remains for pathologists yet to settle.

Staphylococci and the *Streptococcus pyogenes* and other saprophytes, if not present primarily, rapidly develop in the necrotic nidus, and, entering the system through the denuded surface and exposed lymphatics, produce the secondary glandular and serous inflammations, and notably the so frequent and fatal broncho-pneumonia. Accepting this pathology, the local origin of the disease is no longer debatable.

We may say, then, for practical purposes, that diphtheria is caused by the lodgment of the Klebs-Loeffler bacillus or its spores upon a mucous surface, usually the fauces or the nose, most frequently the tonsils; that, there developing and propagating itself in the epithelial layer, it sets up a local exudative inflammation, which is the local expression of the disease, together with greater or less systemic manifestations—at first inflammatory—and to which is rapidly added the toxæmia of the virulent ptomaines or toxalbumins as they are absorbed into the system.

These points being settled, that the disease is contagious, infectious, and local in its inception, the subject of prophylaxis would naturally present itself to us as of primary importance. While it is true that the disease is primarily local, yet, unfortunately, we ordinarily have no warning of its presence until its processes are well under way. But it is reasonable that a thorough and frequent cleansing of the throat with a harmless antiseptic gargle or spray, after exposure or during the prevalence of the disease, is the best preventive measure we have.

The popular practice, first introduced by the profession and now so much in vogue with the people, of giving quinine and whisky as a preventive, is to be condemned, as all the good that can come from it is as a local antiseptic, and for that purpose is much inferior to less unpleasant and objectionable mixtures. Parents should be instructed to teach their children to gargle at a very early age. Last fall, during the prevalence of diphtheria, I taught my baby girl, only a little more than two years old, to gargle, as well as her nine-year-old brother, and this was kept up three times a day during the entire epidemic. The gargle I usually prescribe for this purpose is a saturated solution of three ounces of boric acid with one ounce of eucalyptol compound. This makes a pleasant, non-irritating mixture, well suited to allay the pharyngeal irritation so noticeably prevalent during an epidemic of diphtheria. Its germicidal potency may be easily increased by adding a small amount of bichloride of mercury, which I always do if there has been a known exposure.

Immediate isolation of a case, or a suspected case, is of the utmost importance to prevent the infection of other members of the family. It is immensely better to confine a child to an upper room for two or three days with a suspicious throat, though it prove in the end to be only a simple tonsillitis, than allow a case of malignant diphtheria to slowly develop in the midst of the household, as it not infrequently does. Parents are so gratified if the case is not diphtheria that they are not disposed to censure the doctor for his prompt precautionary measures.

When practicable, unaffected children should be sent away to friends having no children. With these prophylactic measures promptly and thoroughly carried out, there is a strong probability of limiting the disease to the one case in the family. And while speaking of preventive measures I would like to urge the necessity of great care upon the part of the physician himself, especially if he has small children of his own.

Grancher, of Paris, who has had great experience in diphtheria, expresses the opinion that "in nearly all instances diphtheria is communicated by infected articles of clothing and furniture."

The physician can not treat bad cases—swabbing and spraying the throat and nose—without danger of infecting his clothing by the coughing and strangling of the patient. The simplest and best means of protection I have found is a complete rubber suit, consisting of leggings, a long rubber coat, and a skull cap. These are rolled up in a rubber cover and placed in the back of the buggy. With but little delay or trouble, this suit takes the place of the over-

* Read before the Iowa State Medical Society, May 17, 1898.

coat in the vestibule; after visiting the patient it is folded up and placed in its receptacle, and the hands, face, and hair are washed in a bichloride solution instantly prepared by dropping a few tablets in a bowl of warm water. In very malignant cases I take the additional precaution to change all outside clothing, or the disinfection is made more thorough at the office. The rubber suit is easily disinfected by immersing in a bucket of bichloride solution.

It is a noticeable feature that a much larger number of girls have diphtheria than boys. This is probably owing to the fact that girls spend more time indoors.

When many plans of treatment and a multitude of remedies are employed for a given disease, it is evident that none of them give very satisfactory results. There is scarcely a potent remedy in the materia medica which has not been used in diphtheria. In the midst of this mass of conflicting and unsatisfactory testimony, what is the young practitioner going to do for a case of diphtheria? To give my advice specifically on this point is the chief object of this paper. In this I claim but little or nothing original, but merely the appropriation and readjustment of valuable ideas gleaned from many and remote sources, and which have seemed best to stand the test of prolonged experience.

Fever, though not usually a prominent symptom in diphtheria, is generally quite high in the early part of the disease. This is best relieved by moderate doses of phenacetine, which not only reduces the temperature, but quiets the nervous, restless condition nearly always present.

The early local treatment of the throat is of the most vital importance. A day lost at the beginning is often a life lost. The people should be made acquainted with this fact. Twenty years ago, perhaps, Dr. J. Lewis Smith wrote this prescription, which, as a first application to a forming membrane, is a most excellent remedy:

R Acidi carbolici..... gtt. x;
Liq. ferri subsulphatis..... ʒ iij;
Glycerina..... ʒ j. M.

This should be carefully applied to the pseudo-membrane only, with a camel's hair pencil, or, better, a little swab extemporized by twisting a little absorbent cotton on the end of a small stick, like a tapering penholder. This is very disagreeable to the patient unless skillfully applied, and should be used by the physician himself, and not more than twice a day.

When used early, while the membrane is thin, it shrivels it up and removes it, contracts the capillaries, and leaves the denuded surface in a favorable condition. The good to be accomplished by this application is in the early stage, and I think it often aborts or cuts short an attack by exterminating the whole colony at once. If the membrane is thick or there is a high grade of inflammation and a rapidly forming membrane, it is of little or no service and should be discontinued.

A most valuable accession to the list of local remedies is peroxide of hydrogen. I use it from the beginning and as long as there is a vestige of disease left in the throat or nose. I generally use the ordinary fifteen-volume preparation, full strength, sprayed directly on to the membrane

every hour through the day and every two hours through the night with a Phoenix atomizer. This is a little straight instrument which can be used with one hand, while the other holds the tongue down with a spoon if necessary, as it usually is.

Peroxide of hydrogen is a powerful disinfectant and deodorizer, cleans out the throat, and does away almost entirely with the terrible stench which is so characteristic of the disease, and the membrane gradually melts away under its influence. In very young children or when the throat seems irritable the peroxide had better be diluted one half, and always diluted one half or two thirds for the nose; but the full strength sprayed directly against the membrane in ordinary cases is devoid of danger or any objectionable action, and is, in my opinion, the most thorough and satisfactory local treatment yet devised. If from any reason the spray can not be used and a gargle must be substituted, the mixture previously described—of boric acid and eucalyptol compound, to which is added one to three thousand or two thousand bichloride—best meets the indications.

The old gargle of tincture of iron and chlorate of potassium, formerly so much used, is inferior as an antiseptic, exceedingly unpleasant to use, and often painful and irritating to the inflamed throat.

Also from the very beginning I give the following mixture to a child, say, six years old:

R Bichloride of mercury..... gr. j;
Aqua purae..... ʒ iij. Solve.
Eucalyptol comp..... ʒ j.

M. Sig.: A teaspoonful every hour through the day and every two hours at night.

This, with plenty of milk, will be the only medicine given for the first twenty-four hours, or perhaps for the second or third day, as the case may be.

There has been a good deal of complaint of the bichloride causing vomiting. I have heard so high an authority as Dr. Seibert, of the New York Polyclinic, say that the only effect he ever saw from the bichloride was to make the patient vomit.

I used to experience a good deal of trouble while using the bichloride in a simple watery solution or with the fluid pepsin preparations. But with the above-mentioned mixture I seldom have any trouble. It will be retained when anything will. I attribute it to the sedative action of the eucalyptol compound on the stomach.

This preparation is manufactured by Truax, Greene, & Co., of Chicago, and is similar to, though I think an improvement on, the preparation called listerine. It is a five-per-cent. solution of boro glyceride with eucalyptol, thymol, resorcin, menthol, and benzoic acid. The minty flavor completely covers the very disagreeable metallic taste of the bichloride, and leaves a grateful cooling sensation in the throat.

But not merely as a corrigent do I regard the eucalyptol compound in this prescription, but, being a combination of the most thorough non-poisonous antiseptics, is an important adjuvant. Usually on the third day, or on the second day if there are pallor and weakness, I add the following prescription:

R̄ Tinct. ferri chloridi. ʒ iij;
 Glycerinæ ʒ j;
 Syr. Tolu. q. s. ad ʒ iv. M.

Of this, a teaspoonful with a little water, to take the place of the bichloride mixture, every third hour.

You see I have omitted the chlorate of potassium from this prescription. I think its only value is in the small amount of chlorine liberated, and as we now have such an abundance of better disinfectants, we can well dispense with its irritating effect both on the throat and the kidneys.

The tincture of the chloride of iron has stood the test of years as the best agent we have to counteract the rapid destructive processes upon the blood.

As the exudative process diminishes I give less of the bichloride mixture, and when it ceases leave it off altogether, continuing the iron and liquid nourishment, with perhaps a little quinine, and, if there is much weakness, brandy and digitalis. Stimulants are useful on general principles, and when indicated should be given promptly and freely; but I think their value is overestimated.

The weakness of diphtheria is a pure *toxæmia*, and I have never seen any evidence that alcohol is an antidote.

Years ago, following a prevailing fashion, I did what I will never do again—treat a case of diphtheria by beginning to death with nothing but heroic doses of whisky.

As an adjunct to both local and general treatment as well as prophylactic to the spread of contagion, the following mixture, as prescribed by Dr. J. Lewis Smith, our old and reliable authority on diseases of children, is of great importance:

R̄ Acidi carbolici, }
 Ol. eucalypti, } āā ʒ j;
 Ol. terebinthinæ ʒ viij. M.

Of this a tablespoonful or two to a quart of water in a broad, flat-bottomed pan is kept simmering in the room. The steam, loaded with the somewhat pungent though not unpleasant fumes, fills the room, and, if not possessing all the remedial qualities some have alleged for it, the patient certainly breathes easier and the air is made less infectious to attendants and physician.

In diphtheritic croup I believe it is of very great value. The best and simplest way to use it, I have found, is to place at the bedside a little portable kerosene stove on which is placed a teakettle or some suitable vessel with a cover and a large hole cut in the side near the top. A cone or tube is easily improvised from a large sheet of stiff paper and the steam conducted directly to the face of the patient, the quantity and heat being easily regulated by the position. This may be continued for twenty or thirty minutes at a time and repeated at intervals of one or two hours, the vessel simmering in the room in the mean time. These inhalations, together with the free administration of the bichloride mixture, is the best treatment we have for diphtheritic croup.

It is the practice of some to give bichloride in the form of tablets and granules. I think this is to be condemned as liable, in so undiluted a form, to cause irritation of the stomach and bowels, and possibly necrosis of the intestinal glands.

In giving these specific directions I hope no one will understand me as laying down a stereotyped routine treatment to be followed in all cases, but as the general outline of a typical case, to be modified according to circumstances and indications. Neither do I pretend for one moment that these measures, however thoroughly carried out, will save all cases of diphtheria; but constant personal attention to the minute details is the chief element of success in the plan of treatment in this terrible disease.

A CASE OF NASAL HYDRORRHOEA.

By GEORGE F. KEIPER, A. M., M. D.,

LAFAYETTE, IND.,
 EYE AND EAR SURGEON TO ST. ELIZABETH HOSPITAL.

F. B., an architect, consulted me on May 7, 1892, on account of a constant and profuse discharge from his nose which, on account of his occupation, was most annoying. Nothing in his previous history could account for it.

The nares upon examination presented all the characteristics of hypertrophic rhinitis. Treatment was immediately instituted for the reduction of the hypertrophied tissue, but after six months' faithful treatment the discharge continued unabated. All of the remedies ever suggested for relief of similar cases failed here, cocaine included.

After considerable thought upon my patient's condition, I ordered the following:

R̄ Atropine sulph. gr. ij;
 Aquæ dest. ʒ j.

M. Sig.: Spray each nostril morning, noon, and night.

Within two days the discharge markedly lessened, and since then has been in normal quantity only.

The patient suffered some inconvenience at first on account of getting some of the solution into his eyes, but by due caution he has had no trouble since, though he still uses the atomizer.

These cases are rare, and for that reason I report. The treatment as laid down by our authorities is confessedly discouraging, and this case is reported because it has brought in my case atropine into a new relation.

The Death of Dr. Karl S. Walfridsson, a Swedish missionary physician in the lower Congo valley, occurred on May 6th, exactly two years from the time of his arrival in Africa. He was educated in medicine in England and had a qualification from each of the royal colleges. He was an occasional correspondent of the London journals, and in his letters treated frequently of the symptomatology of the "sleeping sickness," a complaint that is very prevalent along the lower reaches of the Congo, where Dr. Walfridsson's mission was situated. His death was caused by a malarial fever that had been severe since January last.

The Death of Medical Director David Harlan, of the Navy, took place at Churchville, Maryland, on July 12th. He was eighty-four years old. He was graduated from the University of Maryland in 1832 and entered the navy three years later. His retirement took place in 1871, after a very active and honorable service. One of his sons, Dr. Herbert Harlan, is a professor in the Baltimore University School of Medicine.

The Death of Dr. Jacob Moleschott, of Rome, took place in May last, in his seventy-first year. Although he was a Hollander by birth and for almost a lifetime a professor in Turin and Rome, he is generally spoken of as a German physiologist. His publications on food, milk, the blood, and muscular structure have been numerous. He was for a time an Italian senator.

SOME SUGGESTIONS IN THE TREATMENT OF PNEUMONIA.*

By A. S. MADDOX, M. D.,

PETROLEUM, W. VA.

A GREAT deal has been written concerning the treatment of pneumonia, but after a study of thirty-six cases in individuals whose ages range from two to eighty, some points have been observed which, although they are not new, may yet be worth mentioning again.

Unlike hospital cases, these were not treated and studied under the most favorable conditions, being distributed over a considerable area of country. I do not aim or expect to advance any new theories or something you all have not read about or used at some time or in some measure in your practice, nor do I wish to tire you with prolix details. But I do wish to reiterate with emphasis some essential if not cardinal points in the treatment of this disease, as well as to discourage and condemn some prevailing methods used by numerous physicians with whom I have come in contact either in consultation or conversation.

In twenty of the thirty-six cases referred to the disease in a general way was to be considered mild, as only one lobe was affected in either the right or left lung, yet in some of the cases the temperature ran as high as 105.5° F. and delirium was well marked. All of these cases were treated in almost a routine manner with slight modification, according to the severity of the symptoms.

Externally, counter-irritation was used with either a spice poultice or a mustard plaster over the side affected, and sponging the surface with cold or tepid water was resorted to in some of the cases of high temperature. In two, blisters of cantharidal collodion were used where resolution was delayed. Internal medication consisted chiefly in the use of carbonate of ammonium from onset to convalescence, and in most of the cases some quinine was given as a tonic throughout the entire course of the affection.

Latterly, as seemed necessary, alcoholic stimulants were administered. All these patients recovered. The remaining sixteen cases were of a more severe type, due to affection of more than one lobe in one lung, and in two cases crossed pneumonia existed. In all of these cases carbonate of ammonium was given throughout the whole course of the disease, and the severer symptoms were met by nitroglycerin and digitalis with very satisfactory results in all but two cases, which succumbed. One of the patients, who died in spite of all remedies, was a young man who had coexisting bronchitis following measles, and the other a man aged fifty-eight who had double pneumonia.

In these cases all remedies given seemed to make no impression. As before stated, I have used nitroglycerin considerably with happy results.

In those cases where a decided weakness of the first sound of the heart existed, and the pulse denoted a tendency to heart failure by being irregular or very quick and feeble, trinitrin was promptly administered in doses of from one one-hundredth to one fiftieth of a grain every fifteen min-

utes to one hour until the effect of the drug could be noted; then was followed by digitalis in doses of from ten to thirty minims every six to eight hours, at the same time continuing the former drug; *e. g.*, in one case—that of a man aged fifty-five, whose respirations were 55, pulse 125 per minute, and temperature 104.5° F.—nitroglycerin was given every fifteen minutes in one one-hundredth-grain doses, and in one hour respirations were reduced to 40, pulse 98, and temperature 103° F. This was followed by digitalis in thirty-minim doses, and the very dangerous condition due to enfeebled heart never returned. Subsequently, alcoholic stimulants were given in large quantities, and Wyeth's extract of malt was ordered by the dozen bottles. Although there was a very slow resolution, which extended over about two months, the patient recovered.

Having only given a glance at the cases, I will summarize the salient points I wish to emphasize.

In the first place, and as seems to me a very important factor in the treatment of these cases, no direct medicinal antipyretics were used, especially of the coal-tar series—a fact that should be particularly observed in the treatment of all diseases where there is likely to be great prostration and depression of the nervous system with a tendency to heart failure.

Some medical men whom I know, and who advocate the use of antipyrine, phenacetine, and acetanilide in pneumonia in the same conditions, have met with terrible disaster, and still continue to use the drugs in this disease.

I should like to urge upon members of this society (if there are any who use these remedies with the hope of reducing temperature) to discard them and substitute some good stimulant, such as we find in the carbonate of ammonium, throughout the course of the disease. Then sponge more and give fewer drugs. In lieu of these, push nourishment and stimulants even to a fault.

Many of the cases mentioned followed *la grippe* and were accompanied by great depression of the nervous system, and had it not been for sustaining measures, I have reason to believe many patients would have died. And now the lesson to be learned from a careful attempt to study these cases it seems to me can be summed up in a few words: That a rational conclusion is to maintain the patient regardless of reduction of temperature only as subsidiary means; to watch for any contingency which may arise and combat it as such; and lastly, but of paramount importance, is to not discourage the heart by tampering with any of the coal-tar derivatives.

The Ohio State Medical Society.—Officers were recently elected as follows: President, Dr. N. P. Dandridge, of Cincinnati; vice-presidents, Dr. F. C. Larimore, of Mount Vernon, Dr. William Caldwell, of Fremont, Dr. W. T. Corlett, of Cleveland, and Dr. L. S. McCurdy, of Denison; secretary, Dr. Thomas Hubbard, of Toledo; assistant secretary, Dr. Charles Graefe, of Sandusky; treasurer, Dr. J. A. Duncan, of Toledo.

Atony of the Bladder.—Apropos of an article entitled *A Curious Condition of the Bladder; Atony?*, by Dr. James Kennedy, published in our issue for June 24th, Dr. Benjamin McCluer, of Dubuque, Iowa, calls our attention to the histories of two cases contributed by him to the *Transactions of the Iowa State Medical Society* for 1884.

* Read before the West Virginia State Medical Society, June 8, 1893.

THE
NEW YORK MEDICAL JOURNAL,

A Weekly Review of Medicine.

Published by
D. APPLETON & Co.

Edited by
FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, JULY 22, 1893.

THE SCOURGE OF THE SUBPŒNA.

IN another column we reprint an editorial article that lately appeared in the *New York Sun* under the heading of Medical Men as Witnesses. We have not seen the text of the act that forms the subject of the article, but, judging from the *Sun's* summary of its provisions, we can only say that it seems to us to be a very short step in the right direction. It is an everyday occurrence for physicians to be subjected to unnecessary hardship by judicial procedure—not, we are glad to believe, with any oppressive intention on the part of the courts, but because of the practical absence of all check upon the exercise by lawyers of the practice of subpoenaing persons on the mere chance of being able to turn them to account on the witness-stand. The *Sun* perceives that practitioners of medicine ought not to be forced into court without good and sufficient reason, but it wonders on what ground the originator of the act in question made its ostensible (but, as the *Sun* points out, unsubstantial) exemption apply to the medical officers of hospitals and other charitable institutions to the exclusion of physicians who are engaged only in private practice. As to the author's intentions we know nothing, but there are good reasons, we think, why hospital physicians are particularly entitled to such exemption, and those reasons are totally different from what the *Sun* seems to imagine.

The public in general and lawyers in particular appear to think that a hospital physician's time is wholly at their service; he is not only to do what he undertook to do at the time of his appointment—namely, look after the interests of the inmates to the best of his ability—but also to grant interviews to newspaper reporters at their convenience and to dance attendance on the courts indefinitely. Consequently such a physician is more apt to be summoned to court unnecessarily than one who is engaged in private practice. Suits for damages for bodily injury are commoner in hospital cases than in those that occur in ordinary practice, and, whereas the citizen who personally employs a physician is usually considerate enough to spare the physician unnecessary trouble and loss of time, the individual who as a hospital patient has already profited by his professional efforts entertains no thought of such compunction. Indeed, it is not uncommon for a medical officer of a hospital to be subpoenaed in a case about which he knows, and ought to be assumed to know, absolutely nothing, as when "the custodian of the records" (so the subpoena often puts it) is required to attend in a trial growing out of a case that has occurred in the practice of the hospital. In his character of custodian of the records he has no personal knowledge of the matters recorded,

and there is nothing to lead any lawyer to suppose he has; yet his attendance is commanded very frequently. This is certainly a hardship for which there is no excuse.

Out of court, lawyers are as just, considerate, and amiable as other men. In court their duties must at times grate upon their kindly inclinations. We feel sure that it is wholly by inadvertence that they annoy physicians in the way we have mentioned. We doubt if the law in question will do much to check them; we look rather to their own sense of justice, now that the matter has been brought to their attention, to lead them to restrain themselves.

CAFFEINE-CHLORAL IN CHRONIC CONSTIPATION.

PROFESSOR EWALD, of Berlin, has made use at the Augusta Hospital of a combination of the two drugs named in the heading. He has found it valuable for the treatment of constipation, when the compound is administered subcutaneously. He has made use of injections of four or five grains dissolved in water, and he has only failed once in thirteen cases of obtaining, as a result, thin stools; in some of these cases the ordinary drugs and free irrigation had been used without avail.

Ewald has also used the compound in a small number of rheumatic cases that had been resistant to the salicylates. In seven out of eight cases the injection of from three to six grains in twenty-four hours has been followed by reduction of pain and swelling in the affected joints. These injections, according to the information given in the Berlin correspondence of *Notes on New Remedies*, are usually not attended by any pain, although in a few cases there was a slight burning sensation at the point of the injection. The well known, but not very uniform, laxative action of caffeine appears to be intensified by the presence of chloral in the compound. If this is a fact, it would seem to be contradictory of certain experiments on the lower animals that have been reported as showing that caffeine, in the presence of chloral, is almost wholly masked. Urea and cyanogen, in like manner, are said to be masked when given with chloral. However it may be as to the overmastering agency of chloral with other substances than caffeine, it seems to be an indisputable fact that caffeine-chloral has a therapeutic future before it in the treatment of chronic constipation.

MINOR PARAGRAPHS.

CARBONATE OF GUAIACOL IN THE TREATMENT OF TYPHOID FEVER.

THE *Medical Week* for June 30th contains an abstract of Dr. F. Holscher's experience in the treatment of typhoid fever by the administration of carbonate of guaiacol in doses of fifteen grains night and morning. With this treatment the tongue became moist, the appetite returned, and the stools, that smelled strongly of guaiacol, gradually assumed a firmer consistence. In some instances the administration of the drug was even followed by constipation, but this usually disappeared spontaneously, seldom calling for the administration of enemata. It exerted a favorable influence on the bronchitis that so frequently complicates typhoid fever, relieved dyspnoea, and facilitated ex-

peccoration. It is not an antipyretic, but an intestinal antiseptic, and has no effect on the temperature when administered alone; but with acetanilide the effect produced is more marked and lasting than that obtainable with any other antipyretic. By its antiseptic action on the intestinal contents it prevents the formation of toxic products in the intestine, and the accidents caused by the absorption of these toxins into the circulation are prevented. Hence the patients treated by this method seldom show any ataxic or adynamic phenomena, and usually remain free from hallucinations and other cerebral manifestations. Dr. Hölcher was enabled to dispense with the use of cold baths, and his typhoid-fever patients never presented other than the mildest symptoms of the disease.

SO-CALLED FÖTAL RICKETS.

THREE cases are reported by Dr. John Thomson in the *Edinburgh Medical Journal* for June. Children are sometimes born with a peculiar deformity characterized by excessive shortness of the extremities and di-tortion of the thorax. They were formerly regarded as cases of fötal rickets, and afterward as fötal cretinism. Examination of the bones, however, has abundantly proved that the condition is not due to either of these diseases. It is called by Parrot achondroplasia, and by Kaufmann chondrodystrophia fötalis. The cause of this peculiar condition is unknown, but the anatomical characteristics are well understood. The deformity results from the arrest of the normal process of endochondral ossification which takes place during uterine life. Hence it occurs solely in the bones which are formed in cartilage and ossify early. Those which are formed in membrane or ossify late escape. The bones of the pelvis and thorax and the long bones of the limbs are, therefore, dwarfed and deformed, while the bones of the skull, trunk, hands, and feet are normal. Death usually occurs before or soon after birth. The three cases reported by the author are especially interesting, as two were in adults and the third was that of a child five months of age.

THE INCUBATION PERIODS OF THE INFECTIOUS DISEASES.

THE Clinical Society of London has recently published the result of extensive observations regarding the period of incubation of some of the infectious diseases. A constant period of incubation is not to be expected. In most instances it will be seen from the following table that the difference in the maximum and minimum period is not very great. It seems remarkable, however, that a disease should show such extremes as typhoid fever:

	Normal.	Maximum.	Minimum.
Varicella.....	12 days.	14 days.	9 days.
Varicella.....	14 "	19 "	13 "
Measles.....	10 "	14 "	4 "
Rubella.....	18 "	21 "	8 "
Scarlet fever.....	2 "	7 "	1 "
Influenza.....	3 "	5 "	1 "
Diphtheria.....	2 "	7 "	2 "
Typhoid fever.....	12 "	23 "	5 "
Mumps.....	19 "	25 "	12 "

It is a peculiar fact that the diseases in which the period of incubation is shortest are those in which the infection may persist the longest. The period of quarantine must be governed largely by the period of incubation, hence the subject is an important one for a variety of reasons. Dr. Dawson Williams, commenting upon these figures in the *Medical Magazine* of London for June, states that the period of quarantine should be at least a day longer than the maximum for each disease. This

is a very uncertain rule, however, for the patient should be free from all signs of illness, and especially from fever. The necessity for disinfection of clothing is shown by cases reported in which persons wearing garments which had been exposed to infection have escaped, while others coming in contact with the same clothes have contracted the disease. This is probably explained by the great susceptibility of certain persons to particular diseases. The period of infection is very doubtful. It may be greatly prolonged by some complication. This is especially true of small-pox, diphtheria, typhoid fever, and scarlet fever. The period during which a disease may be infectious can not be stated definitely. It varies with different cases, and must be determined according to the nature of the symptoms and the character of the case. Measles, chicken-pox, and mumps lose the direct power of infection very early, and the infective principle does not remain active for a long period in the room in which the patient has been ill. Measles, mumps, and chicken-pox may be infectious in the earliest stages before definite or characteristic symptoms appear. Small-pox, fortunately, is not actively contagious until the eruption has appeared. This statement, the committee affirms, has been proved by abundant observation.

A NEW NON-POISONOUS DISINFECTANT, IZAL.

THIS substance is of English origin, and the *Lancet* for July 1st states that it has been approved by Dr. Klein, biologist to the Brown Institution. It is derived from an oil that appears as a residuum from coke-making at the collieries, especially at those situated at Thorncliffe, near Sheffield. As a destroyer of germs, izal takes a higher rank than carbolic acid, but is non-poisonous unless the quantity ingested is very large. Extensive experiments in Dr. Klein's laboratory tend to show that one part of izal in two hundred parts of water is capable of destroying the micro-organisms of diphtheria, scarlet fever, glanders, erysipelas, and cholera.

According to the *Lancet*, the article may be obtained from Newton and Chambers, of Thorncliffe.

ITEMS, ETC.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending July 18, 1893:

DISEASES.	Week ending July 11.		Week ending July 18.	
	Cases.	Deaths.	Cases.	Deaths.
Typhus.....	7	1	2	4
Typhoid fever.....	16	5	18	3
Scarlet fever.....	75	9	64	5
Cerebro-spinal meningitis....	6	7	5	3
Measles.....	204	13	189	5
Diphtheria.....	150	43	111	34
Small-pox.....	3	0	3	0

The New York State Board of Health.—It is announced that Dr. Florence O'Donohue, of Syracuse, has been appointed a member of the board.

The National Guard of Ohio.—Dr. Gilbert I. Cullen has been appointed assistant surgeon of the First Regiment.

Change of Address.—Dr. W. L. Stamper, from Wynnwood, Indian Territory, to McKenney, Indian Territory.

The Death of Dr. William Carson, of Cincinnati, one of the oldest and most highly esteemed practitioners of that city, took place suddenly on Sunday, the 9th inst.

Army Intelligence.—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from July 9 to July 15, 1893:*

The order assigning WALKER, FREEMAN V., Captain and Assistant Surgeon, to temporary duty at Fort Trumbull, Conn., is so amended as to relieve him from further duty at Fort D. A. Russell, Wyoming, and to assign him to station at Fort Trumbull, Conn., until further orders.

MASON, CHARLES F., First Lieutenant and Assistant Surgeon, is promoted to be assistant surgeon with the rank of captain.

KIMBALL, JAMES T., Major and Surgeon, is relieved from duty at Fort Clark, Texas, to take effect at the expiration of his present sick leave of absence, and ordered to Fort Marcy, New Mexico, for duty.

GARDNER, WILLIAM H., Major and Surgeon, on being relieved by Major Woodruff, is ordered to duty as attending surgeon and examiner of recruits at Headquarters, Department of Dakota, St. Paul, Minn., relieving REED, WALTER, Captain and Assistant Surgeon. Captain Reed, upon being relieved by Major Gardner, is ordered to report to the Surgeon General, at Washington, D. C., for duty as curator of the Army Medical Museum and as professor of clinical and sanitary microscopy in the Army Medical School.

CORBUSIER, WILLIAM H., Captain and Assistant Surgeon, is relieved from duty at Fort Wayne, Mich., and ordered to Fort Supply, Indian Territory, for duty, relieving BROWN, PAUL R., Major and Surgeon. Major Brown, on being relieved by Captain Corbusier, is ordered to Fort Hamilton, New York, relieving WOODRUFF, EZRA, Major and Surgeon. Major Woodruff, on being relieved by Major Brown, is ordered to Fort Keogh, Montana, for duty, relieving GARDNER, WILLIAM H., Major and Surgeon.

Book Notices.

Hypnotism, Mesmerism, and the New Witchcraft. By ERNEST HART, formerly Surgeon to the West London Hospital, etc. With Twenty Illustrations. New York: D. Appleton & Co., 1893. Pp. vi-182. [Price, \$1.25.]

This little volume includes certain papers that were originally published by the author in the *Nineteenth Century* and the *British Medical Journal*, and we have no doubt that their republication will prove to be useful and valuable.

The author reviews the old and the new practices of hypnotism, and then gives the details of a recent visit to M. Luys's wards at the Charité Hospital in Paris. Those that have followed the literature of the subject for the last few years will recall M. Luys's wonderful statements regarding what he had accomplished by means of hypnotism, and Mr. Hart was shown these wonderful phenomena. However, he had but a limited amount of credulity, and, as he found that M. Luys was unwilling to apply certain suggested check experiments, he had the "subjects" call at his rooms, and in the presence of a number of scientific gentlemen performed all the experiments that M. Luys had exhibited, and by means of intelligently selected check experiments proved to the satisfaction of those present that the whole performance was a gross imposture. We think that Mr. Hart has proved that Luys's experiments were conducted with incredible looseness in his methods, and that there were incredible extravagance and error in the deductions that he allowed himself to make from the false phenomena to which his mode of experimentation inevitably led.

The volume is written in a style that will enable the lay reader to understand the subject, and it is to be hoped that its wide circulation will correct many of the popular impressions regarding the possibilities of hypnotism. We would espe-

cially commend Mr. Hart's conclusion regarding the alleged advantages of the employment of hypnotism in certain neuroses, in alcoholism, and in the cases of backward or naughty children, that the effect of its employment is to weaken the will power that it is desirable to strengthen.

BOOKS, ETC., RECEIVED.

Nursing: its Principles and Practice. For Hospital and Private Use. By Isabel Adams Hampton, Graduate of the New York Training School for Nurses, attached to Bellevue Hospital; Superintendent of Nurses and Principal of the Training School for Nurses, Johns Hopkins Hospital, Baltimore, Md., etc. Illustrated. Philadelphia: W. B. Saunders, 1893. Pp. ix-17 to 494. [Price, \$2.]

A Contribution to the Pathology of the Vermiform Appendix. By T. N. Kelynack, M. D., Pathologist to the Manchester Royal Infirmary, etc. With Illustrations and Bibliography. London: H. K. Lewis, 1893. Pp. x-223. [Price, 10s. 6d.]

A Manual of Diseases of the Ear. By George P. Field, M. R. C. S., Aural Surgeon to St. Mary's Hospital, etc. Fourth Edition. Illustrated with Colored Plates and Woodcuts. Philadelphia: Lea Brothers & Co., 1893. Pp. x-382. [Price, \$3.75.]

Hypnotism, Mesmerism, and the New Witchcraft. By Ernest Hart, formerly Surgeon to the West London Hospital, etc. With Twenty Illustrations. New York: D. Appleton & Co., 1893. Pp. vi-182. [Price, \$1.25.]

The Health Resorts of Europe. A Medical Guide to the Mineral Springs, Climatic, Mountain, and Seaside Health Resorts, Milk, Whey, Grape, Earth, Mud, Sand, and Air Cures of Europe. By Thomas Linn, M. D., Doctor of Medicine, Faculty of Paris, etc. With an Introduction by Titus Munson Coan, M. D. New York: D. Appleton & Co. Pp. xxiii-330. [Price, \$1.50.]

Lymphoid Growths in the Vault of the Pharynx. By Thomas R. French, M. D. [Reprinted from the *Brooklyn Medical Journal*.]

Colles's Fracture. Illustrated by Photographs of Splints used in Treatment, and by Photographs of Cases. By E. H. Woolsey, M. D., Oakland, Cal. [Reprinted from the *Transactions of the Medical Society of the State of California*.]

The Mutual Interest of the Medical Profession and Insurance Companies in the Prolongation of Life. By Charles Denison, M. D., Denver, Col. (Read before the Section in Medicine of the American Medical Association, June 7, 1893.)

The Relation between Uterine Disturbances and some of the Insanities. By C. C. Hersman, M. D., Pittsburgh, Pa. [Reprinted from the *American Gynecological Journal*.]

Case of Cancer of the Hepatic Flexure of the Colon producing Intestinal Obstruction; Temporary Relief by an Artificial Anus; later Re-establishment of the Continuity of the Bowel by Ileocolostomy by Means of Murphy's Button. By William W. Keen, M. D., Philadelphia. [Reprinted from the *Annals of Surgery*.]

New Inventions, etc.

THE IMPROVED "GRATTAN" OSTEOCLAST.

By A. M. PHELPS, M. D.,
NEW YORK.

WHEN Mr. Grattan, of Cork, Ireland, exhibited his osteoclast before the American Orthopedic Association last September,

and subsequently in my clinic at the Post-graduate School and Hospital, where he performed osteoclasis in several cases, I observed that the "jack" in almost every case lacerated the skin. In other words, the result of the operation was not osteoclasis, but rather osteotomy, because a compound fracture was produced. I had subsequently made an osteoclast by Mr. Ford after Mr. Grattan's model. This was intended to obviate the injury done to the skin, and it accomplishes the desired end.

The screw used by Mr. Grattan, I thought, was too small, and the jack too sharp. The small screw did not propel the jack to and from the bone quick enough, and the jack, being comparatively sharp, cut through the skin. The screw as now made is nearly double the size of Grattan's original instrument, and the jack much blunter. The osteoclast so made, together with another recent addition made by Mr. Grattan himself (I allude to the horizontal bar for holding the jack, instead of a long perpendicular pin held by an assistant), makes one of the most perfect osteoclases I have ever seen. I have discarded the

use of all others, and now more frequently resort to osteoclasis than osteotomy. I formerly preferred osteotomy more frequently than osteoclasis.

The appended figure conveys a correct idea of the instrument.

A MULTIPLE POWDER BLOWER.

By J. W. GLEITSMANN, M.D.,
NEW YORK.

It has been the desire of the writer for some time past to devise a powder blower which would not only permit of doing away with the necessity of filling the cannula each time when used, but also would serve as a receptacle for different powders, thereby uniting several instruments in one, and, if desirable, enabling the operator to use either one powder alone, or two or three combined.

The first experiments were made with an instrument which had stationary cups with stopcocks, through which, when opened, the powder fell into the cannula, from which it could be blown out. Aside from being cumbersome and somewhat heavy, the main disadvantage of this powder blower rested in the difficulty of cleansing, which is always necessary after a

prolonged use of tenacious, sticky powders, such as aristol, euphene, etc. At last a modification of Politzer's instrument was adopted, described by him in the second edition of his handbook on ear diseases.

In the illustration here given we see three movable cups on

a stationary cannula, which is perforated in its whole length. There are attached to each cup little ivory buttons, and one to the cannula. Each cup has an opening at the bottom, which corresponds to a similar one in the cannula, when the ivory buttons of both are in a line. These openings are large enough to allow sufficient powder to fall through, after which the cup is turned downward and the instrument is ready for use. If more powder is desired for the application, the cup is left standing upward, when powder continually drops down. The above cut represents two cups open, one closed (c).

The instrument is very light in weight and does not interfere with the field of vision, because the cannula being filled, all the cups are turned downward, which is important, when the nasal attachment (a) is replaced by the laryngeal tube (b). The whole instrument can easily be taken apart and cleaned, the cups being separated by washers. A small quantity of alcohol quickly removes all the adherent powder from the cannula and the cups. If obstructions are raised to the soft rubber attachment of Rauchfuss (d), by which the physician himself blows the powder out of the cannula, the tubing can easily be replaced by a stationary bulb attached to the cannula, or by a double bulb as used for spray purposes.

The instrument is made with the usual precision by the firm of Tiemann & Co. of this city.

Miscellany.

Our British Brethren.—The recent meeting of the American Medical Association in Milwaukee seems to have met with unusual attention at the hands of medical men in Great Britain. The *British Medical Journal* for July 1st publishes the following:

"The forty-fourth annual meeting of the American Medical Association was held at Milwaukee on June 6th, 7th, 8th, and 9th. After the association had been welcomed by the Governor of Wisconsin, the president of the association (Dr. Hunter McGuire) delivered his address, a large part of which dealt with the aim and organization of the association. The object of the association was to study the origin of disease, its nature and its course, to learn how to prevent it and how it might be cured. Much yet remained to be learned with regard to the endemic diseases of the various sections of the country. In particular many problems remained to be solved in connection with malarious disease. The police regulation of small-pox was a matter involving grave considerations for the General Government and for the several States in the Union. Notwithstanding the dissemination by antivaccination societies of all sorts of misrepresentations, vaccination had been growing in favor, and now the great majority of the educated classes have become convinced of its importance. Compulsory laws have been put in force in the larger number of European countries, and especially in the German Empire, where not only the army but also the people at large

are compelled to submit to vaccination at stated intervals—once every third year being the rule for the army. He said that one of the most important questions of the hour was quarantine, and in connection with this he sketched briefly the spread of cholera during last year and the occurrence of yellow fever in the Southern States at various times. A difficulty in dealing with infectious diseases in America was the rooted dislike to the curtailment of the personal liberty of the citizen for the benefit of the people at large. A further difficulty in the way of the enactment of general quarantine laws was the complex character of the maritime and railroad commerce and travel of the United States. Fully recognizing the difficulties thus created, he yet held that all patriots, representing every shade of political opinion, should unite in demanding of Congress the passage of a law—strong, concise, and yet comprehensive—that will enable the Government to properly protect its citizens against disease whenever, in the discretion of its officers, the emergency may have arisen. There is as much reason why the power of the Federal Government should be invoked to aid in repelling the advent of pestilence as to aid in repelling the advent of a hostile fleet or army. He then touched upon the need for the organization for a National Board of Health, and concluded by a reference to the progress which had been made by the *Journal of the American Medical Association*.

"Mr. Ernest Hart was then introduced, and in a short speech stated that he brought a greeting to the American Medical Association from the British Medical Association.

"Much of the time of the general meeting on this and the following days was occupied by the reception and discussion of various reports of committees.

"On June 7th Dr. H. A. Hare delivered the annual address on General Medicine, which he devoted to a review of Some Practical Advances in Medicine and Therapeutics. The address dealt with the broad facts illustrative of the present status of the non-surgical phases of advance in medicine. The increased scope, variety, and accuracy of diagnosis no longer left any excuse for empiricism; ailments previously considered specific were being recognized as due to some true causative, and therefore curable, disorder. As an example of such evolution in the art of diagnosis, he instanced the case of anemia; when by accurate microscopic devices it had become possible to count and measure the decrease and increase of blood corpuscles in number and size, then a basis for the test and proof of the value of arsenic for pernicious anemia and of iron in chlorosis was obtained.

"On June 8th Mr. Ernest Hart delivered an address to the association on Cholera, Where it comes from, and How it is Propagated. An abstract of this address will be found on page 1. The conclusion of the address, which was listened to by a crowded audience, was received with loud applause, and upon the motion of Dr. Windgate, chairman of the Committee of Arrangements, a vote of thanks was carried by acclamation, and the address was ordered to be printed and copies forwarded to all members of the State boards of health.

"The address in Surgery was delivered by Dr. Henry Mudd, of St. Louis, and was entitled Surgical Problems. The first problem to which he referred was the use of drainage. He said that recent advances had clearly defined a marked difference in the object to be obtained by primary and secondary drainage. While no intelligent surgeon would discard the use of secondary drainage in suppurating wounds, there were many who considered it unnecessary in fresh, clean wounds, whatever their extent. The second problem to which he turned was that of the radical cure of hernia. He thought that while the permanent cure might be hoped for in many cases in children by the use of a truss, such a favorable result in adults was most improbable, and should not influence the decision as to the propriety of operative relief. Permanent recovery followed operation in from sixty to eighty per cent. of the cases, and even the lower percentage justified continued operative efforts. The third problem upon which he touched was that of the treatment of appendicitis. He thought that the treatment of each case must be determined by individual consideration, but added that the anatomical and clinical investigations of the past few years had clearly demonstrated that the theory of the pathology of inflammation in this region which had arisen in America was a correct one.

"Dr. Walter Wyman, of Washington, read the address on State

Medicine, taking for his subject The Extinction of Contagious Diseases. He observed that the history of the world showed that many races of animals had become extinct, and that certain diseases that once prevailed extensively as epidemics had lost their strength or had been so controlled during recent years as to warrant the belief that their histories were closed or fast closing. He pointed out that yellow fever, which had at one time been of frequent occurrence in Europe, affecting Spain in particular severely between 1801 and 1825, that the last epidemic in Europe had been that in Lisbon in 1867. In the same way in the United States the disease at one time had invaded not only the South, but the North, whereas to-day constant vigilance had caused it practically to vanish from the ports of the United States. Since the discovery of vaccination small-pox, though still a stubborn foe, was under restraint, and it was a matter of choice whether or not an individual should be made absolutely proof against the disease. He quoted statistics to show the good effects of compulsory vaccination. Typhus fever, he said, had no permanent lodgment in the United States, and the measures instituted by the Board of Health of New York during the past winter to suppress the disease afforded a striking example of what might be accomplished by laws energetically executed and by disinfection scientifically applied. Finally, speaking of cholera, he foretold that the disease would shortly be eradicated from every English-speaking country by the energy and love of cleanliness characteristic to the Anglo-Saxon race. In conclusion, he touched upon the possible future benefits to be derived from protective inoculation in this and other diseases."

In the same issue of the *Journal* Mr. Ernest Hart, its editor, writes as follows:

"The Milwaukee meeting of the American Medical Association was a very interesting, well-ordered, and lively meeting; the attendance was over a thousand, and from every part of the States. New York, which is heretical on the question of consultations with homœopaths, still holds aloof, but the association is strong enough in the support of the most active-minded professional men in the States to dispense easily with the adhesion of any particular section. In their strong upholding of the *Code of Medical Ethics* as the test of membership, the association has taken up a firm and unassailable position. Since it has acted on the advice which I tendered some ten or twelve years ago, when consulted by Dr. Sayre, Dr. Post, Dr. Pack, and others on the subject of the best means of promoting the growth of the association, the membership has more than doubled, and it is now five thousand. The weak point which I laid my finger on was the evanescent character of the membership, which then depended upon annual delegation from the respective State societies, which are the constituent bodies, corresponding in that respect, but differing in others, from our branches. There are still, however, some other defects of organization, which I think could easily be remedied, but which hinder the growth of the American Medical Association. On some of these I have been in consultation with members of the executive, and have been asked to renew them in writing; they were meantime received with approval. The system of election of the governing body is capricious, and does not provide for stable and complete representation, but leaves room for much canvassing and wire-pulling, and by its elaborate incoherence raises opportunities for side issues and local contests quite irrelevant to the true objects of the association. Some of the principles which at present govern the selection of matter for the *Journal* and the conduct of its editorial department are incompatible with the high scientific, professional, and literary attractions which it ought and might easily be made to present. All this might be altered without additional expense for the moment, and the *Journal* be made to serve the best interests of the association and the profession, and to add largely to its resources, which could then be available for making its pages yet more attractive, so that it should—like the *British Medical Journal*—be the chief recruiting agent for the association. This position, it is acknowledged on all hands, it does not at present occupy, faithfully and ably as it has been edited by Dr. Culbertson and his distinguished predecessors, among whom Dr. N. S. Davis, the founder of the association, holds an honored place.

"My suggestions bear chiefly on the transference of the power of election of the governing body from the 'fortuitous concurrence of atoms'—as it has been described in our columns by a correspondent—

called a 'general meeting' to the county societies, who are the constituent bodies and who should therefore be the elective power. From these representatives should be constituted the subcommittees for detailed work, who should act under and be governed by its authority. There are at present more than one separate controlling committee of 'trustees,' of 'judicial action,' of 'nomination,' etc., who act independently of each other, and are constituted hurriedly and by caucus influence at the general meeting—a system which might well injure any society, and which has more than once provoked deplorable and painfully mischievous schisms. It speaks highly for the inherent and unquenchable vitality of the principle of the association—"broad based upon the people's will"—and of the vigorous love of the profession and the association which actuates the most respected members, that the association has ridden successfully through all such storms. It survives and develops, but with maimed vitality throughout the year, and without that powerful influence on public affairs and professional progress which it might derive from better constituted committees of government, and of public and parliamentary administration, and from a more attractive and effective voice and tongue in its *Journal*. In saying this I speak of new things, and with none but the most appreciative and respectful spirit. The meeting was large and much of the work was first rate.

"Milwaukee is a city of lawns, gardens, and lake, beautifully situated on a bay of Lake Michigan, and with abundant open spaces, well preserved for civic ornament and health. Within the memory of the present generation it was the haunt of the red Indian; it has now a quarter of a million of inhabitants, with fine hotels—Pfister's Hotel, which was the headquarters of the association, is one of the best in the world—public buildings and business palaces, electric lighting throughout the town, and electric tramways. It is the headquarters of lager beer brewers, and the wealthy citizens aided the profession to make the meeting one of generous and continuous hospitality.

"In accordance with the invitation of the association received in Europe, I delivered an address on the Prevention and Proximate Extinction of Epidemic Cholera in Europe—mainly by the purification of the water supply and strict procedure to insure the purity of drinking water. The address, which was based upon an analysis of all European epidemics of the last thirty years, was received, as will be seen from the published reports, with great favor. It was ordered to be printed, and sent, with the indorsement of the association as to the importance of its suggestions, to the executives of all the States and to the State boards of health. That is a compliment which I value even more highly than the kindly enthusiasm and applause which greeted its delivery. At the close of the meeting I was presented by the reception committee with a gold badge enameled with the initials of the American Medical Association and the year of meeting—a souvenir to which I shall attach a permanent value, and which will recall many pleasant incidents of the meeting, some of them too personally complimentary to relate.

"It was particularly gratifying to find the *Journal* held in such high esteem and so extensively read. It was constantly, and indeed without exception, referred to as the chief medical journal of the world; and its usefulness to the practitioner as a helper in his scientific knowledge and daily work was referred to by one medical editor after another at the medical editors' banquet, and by scores of medical colleagues, who specially introduced themselves or were introduced to me for the purpose of thanking the British Medical Association for its *Journal*. If our laws admitted of it we could have some thousands more of members or associates among our English-speaking brethren on the American continent, while limiting ourselves to members of State medical societies legally constituted and of good ethical standing.

"The banquet of the Medical Editors' Association was a most lively and original affair. In so vast a continent, where capitals are situated at often a thousand or two or three thousand miles distant, and with a population of more than sixty millions, it is natural that the astonishing literary activity of the nation should find a corresponding representation in the abundance of journals of all kinds. But I was hardly prepared to be the guest of one hundred medical editorial colleagues—all of regular standing—with three hundred more in reserve. I addressed them on Medical Journalism, in words of which I send a report—disfig-

ured, however, by a great number of misprints and errors due to my 'English brogue' and intonation worrying the reporters. I have only had time and patience to correct some of them; others I must leave to the indulgence of any readers of whatever text or part of the text may be published. It will be gathered from reports in the various medical papers what was the impression produced. It was applauded enthusiastically, and I was assured in all the complimentary speeches that followed, and by innumerable eulogists during the subsequent days, that it will not be without permanent usefulness. Of course I had nothing new to say, but even the scattered and desultory thoughts of however humble an orator gather some force from a lifetime of experience and from the disinterested desire of a stranger to be useful in the utterance of its lessons to himself.

"Altogether, then, my visit to the Milwaukee meeting has, I hope, been useful, as it has certainly been most pleasant, renewing and strengthening the bonds of mutual good will and esteem between the American and British Medical Associations, and promising to promote good understanding and fellowship with our English-speaking brethren in the United States. To me personally it has been a week of hard but happy work, and of much social satisfaction. I am loaded with friendly and pressing invitations to other cities, among them Boston, Philadelphia, Detroit, Cincinnati, Danbury, St. Louis, Louisville, etc., and could easily spend here an active and happy six months in hospitable hands; but as I must be home early in July to continue editorial and Parliamentary work—meantime in such excellent and able hands—I shall be unable to fulfill on this occasion more than a tithe of these proposed hospitable engagements, but shall hope to return later on."

The same number of the *Journal* says editorially:

"Numerous reports and editorial articles in the leading American journals indicate that Mr. Ernest Hart's reception in the United States has been remarkably cordial and stirring. As the invited guest of the American Medical Association, and as specially delegated by the Council of the British Medical Association to the American Medical Editors' Association, Mr. Ernest Hart was, of course, sure of a hearty and hospitable welcome such as our transatlantic brethren so well know how to give. The welcome he received, however, has gone far beyond the bounds of formal official courtesies. It was a spontaneous expression of esteem for the individual and of the strong feeling of brotherhood which exists between the medical profession in this country and in the Great Republic.

"The *Journal of the American Medical Association* had announced Mr. Ernest Hart's approaching visit as an event anticipated with great interest, and many other medical journals had made flattering references to the great part which he has played in the growth of the British Medical Association in his capacity as editor of its *Journal*, for the *British Medical Journal* has long been honored with the esteem and admiring approval, often expressed, of the leading members of the profession of the United States, and has been the theme of appreciative estimates by its medical journalists.

"The profession in Chicago, where Mrs. Ernest Hart's Donegal Industrial Village has created the liveliest sympathy and interest in the World's Fair, and the municipal officers of the city have vied with each other in extending courtesies to him. It appears also that he was expected by the daily press to express opinions on sanitary matters, especially on the prevention of cholera. Judging from the reports which have appeared, Mr. Ernest Hart, while expressing himself with great reserve and deprecating the tendency to exaggerate the possible dangers, has not hesitated to speak in decided terms as to the dangers which may arise from any neglect to protect the water supplies.

"An abstract of his address upon this subject before the American Medical Association is printed in another column, and we refer to its teachings elsewhere in the present issue. We find that the municipal authorities of Chicago placed at his disposal the city steamboat, for the purpose of inspecting the water intakes from the lake. The expedition was conducted by the superintending medical officer of health, Dr. Reynolds, recently appointed, and the party, an account of which is given in the *Chicago Herald* of June 14th, numbered among its members the leading physicians of Chicago, Dr. Owens (the chief medical officer of the World's Fair), Dr. Ingalls, Dr. Love (St. Louis), Dr. Finkler (of Bonn), Professor Reimers (of Hamburg), Dr. Ranch (for many years

medical officer of the State Board of Illinois), besides Professor Jürgens (of Berlin), Dr. Pott (of Vienna), and others, charged with the duty of official report to their invitation.

"The results of Mr. Ernest Hart's observations on this occasion were to be communicated to a meeting of the Chicago Medical Society last week. We gather from the report in the *Chicago Herald*, however, that he was disposed to attribute the prevalence of typhoid fever last season to the use of the polluted water from the inshore intake, now happily closed, and that he warmly approved of the substitution of the new four-mile intake. The report in the *Chicago Herald*, which bears obvious indications of having been altered and dressed up *more Americano*, passes over the 'little defects' with a very light hand, but makes Mr. Ernest Hart's compliments to that magnificent body of water, Lake Michigan, which has been so thoughtlessly fouled, and his observations that Chicago has 'at its doors' the purest water supply in the world, the justification of such sensational headlines as 'The Best Fluid on Earth,' 'Ernest Hart concludes that the Supply from Lake Michigan is the Purest in the World.' These expressions are not entirely borne out by the text of Mr. Ernest Hart's statement, which only indicates that Lake Michigan is capable of supplying an unsurpassed body of pure water when the 'little defects' which he has to point out are remedied.

"The ostrich policy of hiding up the textual warnings by flashy headlines of an opposite significance is not very wise or dignified. To those accustomed to read between the lines the meaning of such devices is plain enough; but it is not every one who will read between the lines. The *Chicago Herald* is one of the ablest and most influential journals in America, and it hardly does well to lull its fellow-citizens into a false security. It should rather stimulate them to accelerate necessary reforms.

"Mr. Ernest Hart's address on Medical Journalism, extracts from which we publish elsewhere, was a more purely literary effort than that on cholera. It contains an account, which can not but be found highly interesting, of thirty years' devotion to the development and consolidation of medical journalism as a power capable of being used as a weapon for the promotion of great medical and public interests. The address ranged over a wide field, touching the mainsprings of the 'higher journalism,' as contrasted with the perverted and, it may be hoped, ephemeral fashions of what is sometimes called the 'new journalism.'

"On the whole, the results of the visit have their obvious international use in promoting international comity, the exchange of views and of greetings. Utterances so candid and fearless may be expected to provoke some wholesome criticism, tempering the chorus, thus far universal, of courteous praise and unqualified acquiescence; but that also is one of the objects and advantages of free speech and the interchange of ideas across the ocean. The universally gracious and complimentary reception tendered to the editor of the *British Medical Journal*, and the admiration everywhere felt throughout the great American republic for the aims, methods, and achievements of the British Medical Association, reviewed and studied from afar and therefore dispassionately and impartially, have found a voice on the occasion of Mr. Hart's visit. Its echoes will not soon die away, but will remain an enduring remembrance, and will form an agreeable and useful episode in the medical history of our time and of the English-speaking race."

The *Lancet* of the same date says in its editorial columns: "Milwaukee seems to be a very desirable place for people to live in unless they happen to follow the medical calling. The American Medical Association has lately held in that city its forty-fourth annual meeting. It was appropriately and warmly welcomed by His Excellency George W. Peck, the Governor of Wisconsin, and by the Hon. P. J. Somers, the mayor of Milwaukee. It is from the address of the Governor that we gather the virtues of Wisconsin as a place of residence. It reminds us of a description of the climate of Australia sent home by one of the early emigrants—that it was so healthy that nobody died there worth speaking of. Wisconsin, according to the Governor, contains within its borders everything necessary for man's comfort except gold—rather an important exception, by the way. Medical men are entirely unnecessary there and people can not tell why they come or how they make a living when they do come. There are cemeteries, it seems, but this is

only for the accommodation of those who become ill in other and less happy climes and who have deferred too long to repair to Wisconsin. Such descriptions recall Arbutnot's account of Weymouth: 'It was such a healthy place that physicians could neither live nor die there.' However unhappy the lot of the resident physicians, the American Medical Association was welcomed in a most hospitable way by the Governor as representing two millions of people—and indeed in a way which seemed to show that the hosts were not without experience of the value of the medical profession. The mayor spoke much to the purpose, and declared that it should be the aim of their law-makers to make their great country a leader in everything pertaining to the health of the community and of individuals. 'It was the duty of commonwealths and municipalities to hold up the hands of members of the medical profession at all times, and especially during the prevalence of epidemic diseases; and public officials who did not do so to the full extent of their powers were guilty of nothing less than treason.' These words are worthy of a place in medical literature. If they represent anything like the sentiment of public men in the United States, we may hope ere long to see the medical profession more recognized in public law than it is now and to hail the triumph of those who seek to raise the standard of medical education and medical examinations throughout the country. One feature in the business of the meeting was the adoption of a report asking for the appointment of a committee of ten to wait on President Cleveland in order to request him to incorporate a recommendation in favor of the appointment of a secretary of public health in his next annual message to Congress. In some form or other we may expect to see such a recommendation acted on by the Government of the United States. It is characteristic of the people of the States that, though fond of personal liberty, they are intolerant of those forms of it which involve injury to others. If the public law is not sufficiently strong or prompt to protect the public health and life from infected individuals they are apt to take the law into their own hands and to rather roughly assert the rights of the majority.

"The meeting itself appears to have been one of interest. The papers read were not of very striking originality. Perhaps we should except two of them from this remark, one of which included tracings in a case of bradycardia—where the pulse-rate was as low as twelve per minute; the patient's only complaint was of headache caused by aural vertigo; no valvular murmur could be detected, but Dr. Ferguson, who detailed the case, believed that there was obstruction somewhere in the aorta. Such cases are very rare, but a rate as low as seven beats has been recorded. We may also note a paper read by Dr. Charles Dennison, whose communication was a plea for a system whereby persons whose lives are insured should be sent, at the expense of companies whose policies they hold, to a suitable climate in case they develop phthisis. The companies are to find the benefit in a prolongation of the time over which the insured continue to pay premiums. It would seem almost as reasonable to suggest that they should be sent at the expense of the medical profession, so that the time over which they paid medical bills might be extended. In both cases the objection occurs to us that the sums paid in averting an evil that might not happen would soon obliterate the advantage of any problematical postponement of the time when the insurance became a claim; but this was not the view of the association, which considered the paper so important as to refer it to a special committee to report thereon to a later meeting of the section. Certainly there were many communications of great interest. Among them we can only mention a few. The address on General Medicine by Dr. Hare was noteworthy; so was the address on Surgery, by Dr. Henry M. Mudd, of St. Louis, in which the advantage of drainage in surgery was placed above all other antiseptic measures except soap, water, and heat. The paper also included a very able discussion of the subject of appendicitis and surrounding inflammations, which, the writer maintained, resulted not so much from concretions as from irritative catarrhal obstructive conditions. Dr. Anders, of Philadelphia, read an excellent communication on Some Points in the Clinical History of Erysipelas, with an analysis of 2,110 cases. He showed that most cases occur in April and that temperature has the least and relative humidity the greatest influence on it. A combination of low barometric pressure with a mean relative humidity most favors the development of the disease.

"We wish all success to the association. It has difficulties to meet in the vast area of its territory and in the consequent varied conditions of life and practice. But it should be supported by the profession, and, as the mayor of Milwaukee suggested, should be welcomed by all communities as representing a calling indispensable to civilization."

The Pharmacology of Acetone.—The concluding portion of an article entitled *Organic Oximides: a Research on their Pharmacology*, by Dr. H. W. Pomfret, an abstract of a paper read before the Royal Society of London, published in the June number of the *Medical Chronicle*, is devoted to acetone. The author says he has examined the actions of acetone on the isolated tissues and organs, and has found that, except in the case of voluntary muscle, these actions differ in little from those of propylaldehyde. Nervous depression is the cardinal feature of the general action of acetone on the frog. Injections have paralyzed the spinal cord. In muscle-nerve preparations acetone quickly depresses the irritability of the nervous path.

It is in its action on voluntary muscle that acetone diverges most from the aldehydes. Pure acetone causes no contractures in muscles, and the muscle irritability is depressed rather than the contractility. In fact, the action of acetone on voluntary muscle he has found to closely resemble that of ethyl alcohol.

On the vessels of the tortoise and excised sheep's kidney, acetone has not been found to possess any action, beyond at times an equivocal contraction.

Acetone is almost innocuous to the frog's heart in all but very strong doses, when the only action is depressed systole with final arrest in diastole.

Seeing, therefore, the resemblance in action found to exist between a ketoxime and an aldoxime, and also between isonitrosoacetone and an aldoxime; seeing, further, the resemblance in action between the involved aldehydes and ketone, it must follow, as a corollary, that the influence of the oxime group must in each case be the same. This influence is that of a nitrite, as was also found to be the case in the aromatic aldimines.

The only discrepancy arises in the actions of acetoxime and of isonitrosoacetone on voluntary muscle. They both give rise, when present in strong solution, to the development of some contracture, a phenomenon which can not be ascribed to acetone.

During the course of this research it has been sought to explain the nature of muscle contracture, and it has been determined that the phenomenon is probably due to direct irritation of the nerve end plates, the irritant in the case of these oximide bodies being an aldehyde, or, perhaps, more accurately, the COH group.

In support of this contention several facts may be here adduced.

It is an active process associated with an increased formation of heat.

Tracings show the onset and decline of contracture to be in relationship with the shortening and lengthening of the latent period.

The development of contracture is prevented by curare.

A primary increase of irritability in the nervous path of muscle-nerve preparations can be traced to the end plates.

This irritability, better expressed as exalted conductivity of the end plates, becomes more marked as the power of the aldehydes to cause contracture increases.

The decline of contracture is synchronous in its onset with the loss of conductivity through the end plates.

Experiments on the oxidation of acetoxime and isonitrosoacetone have led to the detection of an aldehyde—pyracemic or acetylformic aldehyde. This formation of aldehyde, should it take place in the tissues, would then be a sufficient explanation for their giving rise to contracture. On the other hand, it might well be argued that the oxime group, while in all other respects giving rise to actions identical with those of nitrites, yet exerts a primary stimulant action on nerve centers and on the muscle end plates. Such an action this investigation has not disproved.

Persistent Sneezing under Chloroform Anæsthesia.—In the *Indian Medical Record* for May 16th Dr. E. L. Chalke, of Berhampore, gives the following account of a case:

"A well-proportioned Hindu male, aged thirty-four years, was admitted into the Berhampore Municipal Hospital as an in-patient, suffering from complete staphyloma of the right cornea with disorganization of the eyeball requiring extirpation. He had, besides, granular lids of the same eye of some years' standing.

"*Operation.*—As it was decided to remove the eyeball, the patient was placed on the operation table, and I administered the chloroform. When he was completely anesthetized, the district surgeon, Dr. T. J. Hackett-Wilkins, adjusted the stop speculum into the affected eye.

"Almost immediately this was done, the patient began sneezing persistently for a couple of minutes and recovered consciousness. In the meanwhile the speculum had to be removed. The patient was again chloroformed, and when completely under its effects the stop speculum was again adjusted, when the sneezing reappeared, the patient recovering consciousness as before. For the third and last time the inhalation was repeated, when the same events occurred on adjusting the speculum. As he had already inhaled a large quantity of chloroform, it was thought advisable to postpone the operation to a subsequent date. After the lapse of four days he was a *second time* placed on the operation table and chloroform was administered, a hypodermic injection of half a grain of cocaine having been previously given. He was very quickly anesthetized, and, the speculum being adjusted, the sneezing commenced again, and the man recovered consciousness. He was again chloroformed, but on this occasion a four-per-cent. solution of cocaine was dropped into the affected eye at frequent intervals as a local anæsthetic. When completely narcotized the stop speculum was adjusted, but no sneezing occurred, and the operation was performed without any further trouble.

"*Remarks.*—When the patient was chloroformed on the first occasion (three times) it was puzzling to discover the cause of the sneezing, especially when the patient was completely anesthetized—a stage when all reflex actions are temporarily abolished—but on carefully judging the time of the occurrence of the sneezing, soon after the adjustment of the speculum, the idea of combining the effects of cocaine as a local anæsthetic suggested itself, which was adopted only on the second occasion, but not until there had been a repetition of the sneezing as on the first occasion. The cocaine had the desired effect of deadening the sensibility of the eye and stopping reflex action.

"In order to illustrate the physiological action of sneezing in this particular instance, I shall try to explain briefly how this most probably occurred.

"It has been stated that the eyeball was chronically affected for some years from granular conjunctivitis and complete staphyloma of the cornea; consequently the sensory nerves of these structures must have participated in the inflammatory process and become hyperæsthetic. The distribution of these nerves is briefly as follows: The nasal nerve, a branch of the ophthalmic as it passes the inner side of the orbit, gives off three branches, the long and short ciliary and the infratrochlear, which supply sensation to the cornea, sclerotic, conjunctiva, and the integument of the side of the nose.

"The nasal nerve then passes through the shallow groove in the cribriform plate of the ethmoid and divides into an internal and external branch, supplying the mucous membrane and integument of the nose with sensation. It therefore appears that the irritation caused by the pressure of the speculum on the hypersensitive nerve filaments must have been transmitted to the nose by the nasal nerve, and excited the persistent sneezing so characteristic in this case, just in the same manner as the sun's light, falling strongly on the eye, produces a tickling in the nose.

"The next question which naturally suggests itself is, Why should reflex action occur when the patient is completely anesthetized? To explain this particular point I shall quote the words of a favorite authority on this subject: 'All parts of the body do not become insensible in equal times. Certain portions of the skin and subcutaneous tissue retain their sensibility with extraordinary tenacity: these are the matrix of the great toe nail, the margin of the anus, and the whole of the skin of the organs of generation. It is impossible to obliterate their sensibility without pushing chloroform to a degree which greatly surpasses that required for ordinary purposes.'

"As mentioned previously, the patient was perfectly anesthetized and the conjunctivæ and corneæ insensible to the touch of the finger, and the man was, for all ordinary purposes, sufficiently narcotized for the operation, but, owing to the hyperæsthetic condition of the nerves of the eye, reflex action was not completely annihilated, and the speculum being of a hard nature, pressing forcibly on the nerves, excited the sneezing."

Linear Craniotomy for Microcephalia.—Dr. John Barlow, surgeon to the Glasgow Royal Infirmary, contributes the following to the June number of the *Glasgow Medical Journal*:

"The case which I bring before you to-night is a girl, M. T., aged two years and eleven months, who first came under my notice in the Dispensary of the Glasgow Royal Infirmary nine months ago. Her father, an intelligent man, sought advice because the child could not walk or talk, and did not recognize any of the members of the household."

"Her condition was noted on three occasions at intervals of a month, and, as no improvement occurred, she was admitted into the Infirmary on the 23d of November."

"The histories of the father, aged twenty-nine years, the mother, aged twenty-six years, a sister, aged five years, and a brother, aged seven months, present nothing of interest. There is no history of syphilis. I was told that the mother never noticed the presence of the anterior fontanelle after birth in the girl. The mother thought that something must be wrong with the head of the patient's baby brother because it had the open fontanelle. It was noticed that during the first year after birth the child was in a sleepy or drowsy condition."

"When the girl was fifteen months old she burned her fingers three times in one day by placing her hand upon a hot teapot, but she did not cry much."

"She has never shown any interest in or recognized those about her. The father, who is evidently much attached to the girl, is quite sure that she does not recognize him. The parents naturally contrast the amount of intelligence manifested by the patient with that of her baby brother, who is two years younger and who knows them quite well, and whose eyes follow a train and animals at rest or in motion."

"She always passed her faces without giving notice, and during the last three months she has on several occasions eaten faces. When sleeping she cries out sometimes, and when awake she is often sitting up and the body swaying backward and forward. She has never had a 'proper cry,' but when she is restless the parents offer food, which is always taken. No preference for any particular kind of food has been noticed."

"On looking at the child, attention is arrested by the small head and relatively large face. The body generally is fat, but flabby. Measurements of the head gave the following results:

"Circumference at one inch above orbits in front, and occipital protuberance behind..... 17 inches.

"Antero-posterior diameter..... 6 "

"Diameter between parietal eminences..... 4½ "

"Diameter of skull at points one inch behind external angular process of frontal bones..... 3½ "

"Similar measurements were made of the head of a delicate girl of the same age who was in hospital, and in all there was an increase. There was a difference of one inch in what I may call the bifrontal diameter:

"Circumference..... 18½ inches.

"Antero-posterior diameter..... 6½ "

"Biparietal..... 5 "

"Bifrontal..... 4½ "

"The child could not walk, and could not stand erect without support. All the special sensations were blunted, and this was especially marked in the cases of sight and hearing."

"The reflexes—patellar, plantar, and pupillary—were apparently normal. The skin of the limbs, and especially of the legs, was cold relatively to that of the uncovered head, and was of a dull-red color."

"The girl was watched in hospital for four weeks, and during this time confirmation was obtained of the points to which I have referred."

"On 21st December the operation of linear craniotomy was per-

formed, with the assistance of Dr. Pringle. Chloroform having been administered, I made a curved incision six inches in length—the highest point of the convexity being near the median line—through the scalp upon the left side of the head. This incision extended to the pericranium. The flap thus marked out was raised from the skull. Two small arteries having been secured, a half-inch disc of bone was removed by means of a trephine at a point an inch and a quarter from the middle line, corresponding to the center of the skin incision (about midway between the anterior and posterior borders of the parietal bone). Into the hole thus made I introduced Keen's bone-cutting forceps, and by them [sic] I removed a strip of bone a third of an inch in width and extending from the trephine opening anteriorly and posteriorly for fully two inches, the portion removed corresponding to the skull from a little in front of the coronal suture to a point an inch above and an inch to the left of the external occipital protuberance. The pericranium was removed and subdural space was not opened. The flap of the scalp was then put in position and retained by a few silk worm-gut sutures, and the wound dressed in the ordinary way. The operation occupied thirty-five minutes."

"The after-history is very brief. The wound was dressed upon the 27th, and was found united by first intention. The highest temperature registered was 99°2° F., and there was little or no shock. On the 2d January she was removed to her home at Coatbridge, arrangements being made for her return in three weeks."

"The only change noticed since the operation was the increase in the temperature of the legs, and, on one occasion, the exercise of choice by the girl in the matter of food—she pushed away a cup of milk, but seized and ate a biscuit."

"On the 18th January I heard that the girl was keeping well and that some improvement could be noticed in her mental condition, but she could not be brought to hospital, as her sister had measles and she herself was sickening. On the 6th February her father wrote me that that she was better of the measles, but was very weak and took almost no food. He says, 'I am very sorry she has come home to get this backset, for I think she was getting on well before she took the measles.'"

"On the 7th February I went out to Coatbridge and found the girl in the languid condition common after measles, and heard that during the previous night she had got out of her crib and had aroused the father by going to his bed and putting her arms around him."

"On the 30th March I heard that the girl had recovered from her illness, and arrangements were made for her return to hospital, so that her condition could be noted."

"*Present Condition* (four months after operation).—In certain respects there is evident improvement. She can now walk without support, but with some uncertainty. The sensation of hearing is more acute, and she takes more notice of her surroundings. She can not talk, but she can indicate by sound that she wants food. It is less difficult to prevent soiling of bed linen by her excreta. She recognizes certain people, and will sometimes hold out her hand to me when I go near her bed. She still occasionally, when sitting in bed, swings the body backward and forward, but these rhythmic movements are not observed so frequently. She is quieter and much more easily managed."

"The bifrontal diameter is now four inches and an eighth instead of three inches and three quarters—an increase of three eighths of an inch."

"It is not my intention to deal to-night with the question of the relationship of the defective development of the brain to the early obliteration of fontanelles and of the sutures. There are those who, like Broca, regard the arrested developments and growth of the brain as the primary lesion, and the changes in the cranial bones as secondary; and others, as Virchow and Russell Reynolds, are of opinion that, owing to some defective nutrition, there is a premature obliteration of the cranial sutures, and, as a result of this, interference with the growth of the brain."

"If the former be correct, such an operation as I have described would be justifiable only to relieve pressure symptoms, such as perhaps the rhythmic involuntary movements of body or a portion of the body. If the latter—considering the life history of microcephalics, even when liv-

ing under special conditions, as in institutions, where we have living beings whom it is necessary to feed and clothe, who can not speak, and who are simply restless or unquiet if their appetites are not satisfied, and who thus live on unchanged—the operation of linear craniotomy might be performed with the object of lessening the pressure on the brain, giving the brain, as has been said, 'elbow room,' and allowing of its growth and development.

"Up to the present time the operation—or some operation by which portions of the cranial bones have been removed or divided—has been performed thirty-eight times, with four deaths. In two, death occurred within three hours after the operation, probably from shock; and in one, death occurred on the third day after operation with hyperpyrexia. It is yet too soon to speak positively as to the results of the operation in those who recovered. By the operation there is lessened one obstacle to brain development, and education, systematic and thorough, is necessary to bring about the slow development of mental power.

"In the case which I now show you no obvious increase, except in the bifrontal diameter, has occurred in the diameters of the skull. Such increase could not occur from removal of a strip from one side. It is my intention, however, at an early date, to remove a strip from the right side of the skull, and to connect the two furrows by removing a strip extending across the middle line from one to the other. There will then be a means of expansion laterally and from before backward. It was my intention to do this second operation at the end of last January, but the illness from measles has caused delay. I hope to have an opportunity of showing you the girl at some future meeting.

"[6th May, 1893.—The second operation was performed on 25th April, the wound was dressed five days later and was completely healed, and the child was sent home to-day.]"

Medical Men as Witnesses.—"A remarkable law concerning the examination of medical men as witnesses in negligence suits," says the *New York Sun* for July 14th, "went into effect in this State at the beginning of this month.

"It relates to the testimony of physicians or surgeons who are attached to any hospital, dispensary, or other charitable institution. Where such a man is required to testify in an action for the recovery of damages for personal injuries, in respect of information which he acquired in attending a patient at the particular institution to which he is attached, the new statute requires that the testimony shall be taken before a referee instead of being given in court before the judge and jury, as has always heretofore been the practice. However, the judge of the court in which the case is pending is empowered at any time, notwithstanding the fact that the deposition of the medical man was taken before a referee, to make an order requiring his examination upon the trial.

"The precise purpose of this change in legal procedure in reference to medical witnesses is not plain. Probably, however, the idea of the framer of the law was to relieve hospital surgeons and physicians from the burden of having to attend court at hours when it is inconvenient for them to leave their duties at these institutions. But it is to be noted that nothing is said in the statute about the place where the referee is to take the testimony, and it might well happen that it would be as difficult for a doctor to obey a summons to appear before a referee at his office as it would be to obey a similar summons to attend court.

"One objection to the new practice contemplated by this statute is that it will compel juries in many cases, so far as the evidence of doctors is concerned, to render their verdicts upon depositions which are read to them, instead of upon the oral testimony of witnesses given in open court. The appearance of a witness, his demeanor, and his manner of testifying, always afford the utmost aid to an intelligent jury in passing upon his credibility and the weight which ought to be given to his testimony; and it is a serious matter to withhold this aid, and to substitute evidence which is read by a lawyer from a written or printed document for the evidence of the witness given by his own word of mouth in the presence of the court. As has well been said by an eminent judge, 'all witnesses look alike in print.'

"We suppose it may be argued in support of this enactment, that physicians and surgeons ought not to be called away from important

cases where life is at stake, in order to dance attendance in the courts, oftentimes unnecessarily by reason of the repeated postponements of trials. No doubt there is force in this suggestion, but we think it will be found upon inquiry that our courts are very indulgent toward physicians whose engagements render it difficult for them to attend at any particular time, and that adjournments are often granted and testimony is frequently taken out of order so as to enable doctors to appear as witnesses without detriment to their practice.

"But, if it be true that medical men require the protection of such a statute, why is it confined in its operation to such of them only as are connected with hospitals, dispensaries, and charitable institutions? It would seem that these doctors are the very ones who could most easily obtain assistance and find others to take their places in case of an enforced attendance in court, while the private practitioner, who has no hospital work, might find it very difficult at short notice to procure the aid of another physician or surgeon to look after a critical case under his charge."

To Contributors and Correspondents.—*The attention of all who purpose favoring us with communications is respectfully called to the following:*

Authors of articles intended for publication under the head of "original contributions" are respectfully informed that, in accepting such articles, we always do so with the understanding that the following conditions are to be observed: (1) when a manuscript is sent to this journal, a similar manuscript or any abstract thereof must not be or have been sent to any other periodical, unless we are specially notified of the fact at the time the article is sent to us; (2) accepted articles are subject to the customary rules of editorial revision, and will be published as promptly as our other engagements will admit of—we can not engage to publish an article in any specified issue; (3) any conditions which an author wishes complied with must be distinctly stated in a communication accompanying the manuscript, and no new conditions can be considered after the manuscript has been put into the type-setters' hands. We are often constrained to decline articles which, although they may be creditable to their authors, are not suitable for publication in this journal, either because they are too long, or are loaded with tabular matter or prolix histories of cases, or deal with subjects of little interest to the medical profession at large. We can not enter into any correspondence concerning our reasons for declining an article.

All letters, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication. No attention will be paid to anonymous communications. Hereafter, correspondents asking for information that we are capable of giving, and that can properly be given in this journal, will be answered by number, a private communication being previously sent to each correspondent informing him under what number the answer to his note is to be looked for. All communications not intended for publication under the author's name are treated as strictly confidential. We can not give advice to laymen as to particular cases or recommend individual practitioners.

Secretaries of medical societies will confer a favor by keeping us informed of the dates of their societies' regular meetings. Brief notifications of matters that are expected to come up at particular meetings will be inserted when they are received in time.

Newspapers and other publications containing matter which the person sending them desires to bring to our notice should be marked. Members of the profession who send us information of matters of interest to our readers will be considered as doing them and us a favor, and, if the space at our command admits of it, we shall take pleasure in inserting the substance of such communications.

All communications intended for the editor should be addressed to him in care of the publishers.

All communications relating to the business of the journal should be addressed to the publishers.

Contributors who wish to order REPRINTS of their articles should do so on a blank prepared for that purpose, which will be sent to them by the publishers on receipt of a request to that effect. The order should be sent to the publishers, and not to the editor.

Lectures and Addresses.

ADDRESS OF THE PRESIDENT

AT THE OPENING OF THE FIFTEENTH ANNUAL CONGRESS
OF THE AMERICAN LARYNGOLOGICAL ASSOCIATION,

May 22, 1893.

By MORRIS J. ASCH, M. D.

FELLOWS OF THE AMERICAN LARYNGOLOGICAL ASSOCIATION: It is my duty first to thank you for the honor you have conferred upon me by electing me to the presidency of this association—an honor enhanced in value when I remember those who have preceded me in this chair; and, secondly, to bid you welcome once more to this city, where the American Laryngological Association held its first meeting on June 10, 1879; where, in October, 1873, the New York Laryngological Society was formed for the study of the larynx, pharynx, and adjacent parts—the first society formed for the purpose in any country, and from which our own association has been the natural outcome. Those of you here to-day who were present at that meeting will recall the enthusiasm of our first president, his words of counsel, and his prophecies of the future of laryngology. Were he here with us to-day, how more than satisfied would he be with the fulfillment of his hopes, reaching far beyond his most sanguine expectations! In his inaugural address he pleaded for the establishment of professorships of diseases of the throat, for the foundation of special hospitals, and for the addition of departments for the treatment of these diseases in hospitals already established. At the time he spoke there were in all this country but twenty-five teachers of the specialty; of these, but two taught laryngology exclusively; the other twenty-three combined their instruction with lectures on the diseases of the eye, ear, or chest. To-day laryngology is an intrinsic part of medical education, and the opportunities for its study, clinical and didactic, are universal. This result is largely due in this country to the industry, the genius, and the perseverance of Louis Elsberg, our first president, the pioneer of laryngology in America—its first professor here and the founder of the first clinic for diseases of the throat in the United States and perhaps in the world.

The literature of the specialty was so scanty and so scattered in 1879 that it was suggested that the association, as one of its functions, should prepare a digest of the progress of laryngology, compiled from the publications appertaining to it, and that this digest be supplied to the fellows and to outside subscribers. To-day not only are the special journals in excess of the need, but almost every medical journal, besides publishing articles by laryngologists on laryngology and rhinology, has its report on the progress of the specialty. It must be a source of gratification to the older members to witness the change. The younger specialist of to-day can scarcely appreciate how different are the conditions to-day. He can scarcely believe that, even so lately as the first meeting of this association, the laryngologist was looked upon by the older gen-

eration of medical men with a certain amount of distrust. The laryngoscope was considered a sort of physiological plaything, and I well remember the amused incredulity shown by one of our prominent medical men when he was told that tubercular laryngitis could be diagnosed by it prior to any pulmonary manifestations. That to-day the study of these diseases is universal, and knowledge of the laryngoscope part of the training of every American physician, is, I sincerely believe, due in this country to the influence of the members of this association, who have conscientiously upheld its importance and have given it dignity by the conscientiousness of their work and the value of their researches.

At the time the association was formed it was the belief of some of its founders that its members should be drawn only from those who directed themselves wholly to the study and practice of the specialty, but it was not meant that the laryngologist should be only a laryngologist, or that the specialist should be dissociated from general medical science; no one knew better than these men that to be a good laryngologist it was necessary to be thoroughly trained in every department of medicine, and that not theoretically, but practically; but it was deemed wisest, in the inception of the association, that its majority should be composed of those who were prominent in the specialty, and thereby give it importance in the eyes of the rest of the medical world. For myself, I am fully in accord with the advice of Mackenzie to the younger members of the British Laryngological Society that, while devoting themselves to their specialty, they should continue to practice general medicine and surgery during the first ten years of their career. In his inaugural address at their first meeting in 1888 he says: "It is impossible that a man can be a really good specialist without possessing a general knowledge of disease, and when I say general knowledge I do not mean such a knowledge as can be obtained in a student's career, or even such as can be acquired by the holding of minor appointments at the termination of a hospital curriculum; what I consider requisite is such a familiarity with morbid processes as can only be acquired by those who are in the habit of using all the resources of their art in combating the great varieties of ills which flesh is heir to. In my opinion, only those who have acted as general practitioners for some years, or have held appointments as physicians or surgeons to general hospitals, are thoroughly equipped for practicing as specialists. It is only after thorough knowledge has been obtained in many departments of medicine that training and experience can be focused with advantage on a single point" (Presidential Address delivered at the first meeting of the British Laryngological Society, November 14, 1888).

These words of the great master are most true, and I commend them to you when you are called on to advise a young graduate in his selection of a career.

Much that was pointed out at our first meeting as being needed has been accomplished. The plea for systematic teaching has been heard, and in all the post-graduate schools and in the medical colleges of this country laryn-

gology finds itself the equal of any of our sister specialties. Am I claiming too much for this association when I say that to the men who formed it fourteen years ago this result is largely due? The advance in our knowledge of the pathology and therapeutics of diseases of the throat and nose since that time is known to you all. Very crude, comparatively, were the appliances and methods of that time. The galvano-cautery was an uncertain agent. How many of us beginning an operation with it had to complete it by some other procedure? The electric light was a thing unknown, and the application of the electric motor to nasal surgery had not been foreshadowed. Laryngeal tuberculosis was an incurable disease. Krause and Heryng had not yet given the results of their labors to the world, and the removal of the larynx was an operation that made the boldest of us shudder. Our armamentarium was limited in comparison with the instruments we now possess: a Mackenzie's lamp and reflector; laryngeal and pharyngeal mirrors; a set of forceps—Mackenzie, or some other pattern; Schrötter's tubes; Storck's guillotine, some brushes, and applicators; a powder blower, with a number of extraordinary instruments, usually the invention of the specialist himself—and utterly useless in the hands of any one else—constituted our working capital. What we possess to-day of appliances and instruments I need not detail to you. Every day brings forth something new, either in the form of an instrument, some new pathological fact, or some method of relief or cure. That all of these will prove to be valuable I do not assume, but out of the vast mass which is being heaped up by the faithful workers something will surely be extracted that will bring honor to its author and relief to mankind. The study of the physiology and diseases of the anterior and posterior nasal passages and their accessory cavities has given us most valuable results, and so closely has their relation been traced to diseases of the ear that now the treatment of these last diseases is coming within the domain of the laryngologist. The ophthalmologist invokes his aid also in diagnosing and treating the catarrhal affections of the eye. To one of our own fellows, too early called away from the theater of his labors, Dr. Hooper, of Boston, a great part of this is due.

If, then, in fourteen years so great an advance has been made, it is not too much to expect that in the near future the value of our work will be increased, and the result of the labors of this association will give added knowledge to the world in every branch of our specialty. I speak advisedly when I say the labors of this association, for I believe that most valuable work is being done by it, and the incentive of our annual meeting elicits in its papers the results of faithful observation and laborious research, while their discussion is sure to bring forth opinions and facts from the members which their large clinical experience renders most valuable.

It is a matter of congratulation that our association is so largely composed of those who, by their position as teachers or at the head of extensive clinics, are so thoroughly competent to pass judgment. While, then, we look forward with anticipation to the work yet to be done, and

encourage the ardor of those who, zealous in their task and prominent by their success, are still foremost in the pursuit of knowledge, we must also halt to mourn the loss of one who has fallen by the way, in the vigor of youth and in all the glory of his intellect. Such a loss has befallen us in the death of our late associate, Dr. Franklin H. Hooper. Although still young, he had made his mark as a faithful and able investigator. Thoroughly trained in the laboratory of Harvard, he brought to his work, with the capacity developed by a thorough education, the desire to utilize to the fullest degree the advantages he enjoyed. When we were last year in Boston his absence from our gathering was a disappointment to us all, for all missed the eloquent learning which would have illuminated our discussions, the zeal with which he would have defended his opinions, and the gentle courtesy which would have added grace to our social intermissions. His scientific work is known to all here. His labor in demonstrating the relation of adenoid hypertrophy to ear diseases was at once appreciated by the medical profession, and was the means of bringing into general notice the operation for its removal which has since become so universal. Such a void as the death of Dr. Hooper causes is difficult to fill; and it is fitting that at this meeting, the first held by the association since his death, it should cause to be placed in its *Transactions* its appreciation of his merits and its sincere regret at his early demise.

At its present meeting the association will be called upon to take action on certain amendments to the Constitution and By-laws, of which notice has been given by the secretary, and it will also decide in what manner it will utilize the time allotted to it at the coming Congress of American Physicians and Surgeons at Washington in 1894. It has been decided by the executive committee of this body that an hour and a half of each session shall at its next meeting be occupied by one of the participating organizations, and that each society selected to perform this duty shall prepare its own programme for the period assigned to it by the committee, and select its own speakers. You will decide in what way this time shall be occupied: whether by the reading of papers or by a discussion on some question of interest to the general profession as well as to the specialist; and you will also indicate whom you elect to represent you on this occasion.

Now, gentlemen, as the time of our session is limited, and as there are several papers of interest on the programme for to-day, I will not detain you longer, but bid you Good-speed in your work. Knowing what we have already accomplished, I confidently trust to the members of this body to continue their labors for the advancement of our specialty in the future as faithfully as in the past. As teachers, as workers in the difficult path we have chosen, and as worthy upholders of the dignity of our task, each and every one of you will reflect credit on the profession. It is with no desire to magnify the importance of this association if I say that to its labors I believe is largely due the practical advancement that has been made in late years in the treatment of diseases of the throat and nose. That it will continue to do so in the future I sincerely trust. The

older fellows have nearly fulfilled their allotted tasks; on the younger members will devolve the honor of continuing the good work that has been begun, and we know that our standard will be borne right manfully.

If I might be permitted to give a word of counsel in the capacity in which I stand before you to-day, I would urge the importance not only of studying but of teaching our art. There is no incentive to acquire knowledge equal to that of imparting it. It will keep you in the front rank, for to disseminate it is necessary to possess, and one must always be abreast of the progress of the day in order to honestly satisfy the requirements of the student. An Eastern sage once said: "Much have I learned from my teachers, more from myself, and most of all from my scholars." Take the lesson to yourselves, and in its fulfillment you will find the reward of your work.

Original Communications.

THE TREATMENT OF GRANULATING WOUNDS.*

By W. W. VAN ARSDALE, M. D.,

ADJUNCT PROFESSOR OF SURGERY IN THE NEW YORK POLYCLINIC;
ATTENDING SURGEON, GOOD SAMARITAN DISPENSARY;
ASSISTANT SURGEON, NEW YORK CANCER AND MOUNT SINAI HOSPITALS.

The great advances made in the methods of treating and dressing wounds within the last few years have consisted chiefly in substituting more and more (as our technique improved) aseptic for antiseptic surgery.

To the reader of the literature on wound dressings and on the management of wounds a tendency becomes manifest on the part of the authors to interfere with the normal process of repair as little as possible, and this as a direct result of biological methods of investigation.

These advances, however, almost all pertain to the treatment of primary wounds—that is to say, to fresh surgical wounds intended for primary union, which naturally absorb most of the interest of the surgeon. Indeed, the results which we witness in primary operations are so gratifying in certain cases that we do not hesitate to accept the methods advocated in our literature and very generally in use as fully adequate for our present purposes. And although we may continue to improve in our technique, the improvement will probably be more in the direction of uniform success and in combating those general systemic conditions more removed from the field of operation (although influencing the behavior of the wounds none the less on that account), and amenable to treatment by methods other than purely surgical.

But if in many of our hospitals we see beautiful results after primary operations, where the wound could be closed and left unmolested, we also see, principally in our dispensaries and in general practice, a number of wounds which must of necessity heal by secondary intention, and

in contemplating these we can not but feel that their management might be improved.

In the more recent literature these granulating wounds appear comparatively neglected, although the subject is certainly an important one on account of the frequency with which these wounds are encountered in daily practice.

I do not at present refer to such injuries as certain scalp wounds which, although originally contused wounds, can be readily transformed into clean-cut wounds and healed by primary intention. But I refer mainly to those contused and lacerated wounds where death of the tissues, more or less extensive, takes place in consequence of the primary injury and which therefore heal of necessity by granulation.

It is my lot to have referred to me for treatment a number of patients suffering from granulating wounds who have previously been under treatment by others either at their homes or at clinics and dispensaries.

From observation of such cases, I find that it is a very general practice to treat granulating wounds in much the same manner as primarily aseptic ones are treated. The most frequent dressing met with consists of iodoformized gauze placed directly over the wound, with more or less absorbent gauze or cotton, or both, over this, held in place by a bandage. The idea underlying this proceeding is to keep the wound dry, and by inspissating the secretions to prevent their becoming putrid.

As a consequence, however, of this dressing, and *whether the wound when first seen was put through a course of antiseptic cleansing or not*, we very frequently find conditions of inflammation present in these wounds due to the accumulation of the secretions on the wound and in the surrounding tissues—conditions for which we may use the familiar term retention, and which disappear with the establishment of free drainage.

These wounds appear reddened and swollen at the edges, the surrounding tissue presents a phlegmonous infiltration, there is much local pain, especially on pressure, and the patient is somewhat feverish and ill at ease.

I am well aware that it is very generally maintained that by thoroughly disinfecting these wounds which are expected to heal by granulation, we can get them to heal without any appreciable amount of secretion or suppuration, and it was thought for a time that these wounds could actually be rendered free from micro-organisms.

We know, however, from bacteriological investigations by Bosowski, Ghrisky and Robb, Lang and Flach, and others that even in our primary wounds, treated either by the antiseptic or the aseptic methods, numerous micro-organisms are always to be found. It is therefore not probable that we can hope to render and maintain our granulating wounds entirely free from micro-organisms.

If we do meet with granulating wounds, however, which show no perceptible amount of secretion, we encounter a further disadvantage of the dry iodoformized dressings, in that the gauze sticks tightly to the wound and can not be removed without lacerating the granulations.

The method most commonly used to prevent retention

* Read before the Section in General Surgery of the New York Academy of Medicine, June 12, 1893.

in granulating wounds consists in dampening the dressing with some aqueous solution and covering it over with a layer of protective impermeable to air. This is what I shall here term the moist dressing. It is in general use for certain infected and sloughing wounds, where it certainly renders excellent service.

From time to time, however, articles appear in our literature recommending the use of moist dressings for all wounds, and especially for granulating or partly sutured wounds (Weber).

The advantages alleged for these dressings are the following: There can be no retention of secretions under them, since drainage is always complete; consequently depletion of the tissues ensues, and with it increased circulation and more rapid repair. There is no pain, because there is no tension. There is no elevation of the bodily temperature from absorption. Moreover, they can be quickly and painlessly removed. But those who have tried the extensive use of moist dressings are not all satisfied with them, at least not for general use.

These dressings, by keeping the surface of the wound always warm and moist, act as poultices, and increase the secretions from the wound inordinately. The granulations are apt to become exuberant, and this retards the healing of the wound. The aqueous solutions very frequently cause annoying eczematous conditions of the skin in the environment of the wound, especially in the poorer classes, or when sublimate solutions are used. Acute oedema with exfoliation of the epidermis is of common occurrence, and not infrequently we meet with a painful acute oedema of the areolar tissue beneath the skin.

The proliferation of all kinds of bacteria in these moist dressings soon renders them putrid; and especially in the sublimate dressings where the sublimate is rendered inert by the action of the albumin in the secretions (formation of albuminate of mercury insoluble in water). Therefore frequent change of dressings is necessary. The natural transpiration of the skin surrounding the wounds is somewhat interfered with by the use of the rubber tissue. If there is any sloughing, this process is much more extensive than it would be if the wound were kept dry, and the scar forming after these wounds have healed is consequently dense and distorting and oftentimes painful. Finally, the chemical antiseptic substances used in these dressings irritate the wounds and make them appear inflamed—so much so that almost all wounds which we see in these antiseptic days are actually irritated wounds.

Of late, and especially since the appearance of Dr. Halsted's admirable paper on the treatment of wounds, many granulating wounds are dressed in this city in a manner somewhat similar to that advocated by Schede for healing wounds under the moist blood-clot.

Over the wound, disinfected if necessary, is placed a small piece of gutta-percha tissue, over which absorbent material is held in place by a bandage.

Of those wounds so dressed by others which have happened to come under my observation, as well as those which I have myself treated in this manner, the majority have been far from satisfactory.

However small the piece of tissue was cut to cover the wound, the wound has always presented reddened and swollen edges, been painful to the touch, and had a macerated appearance. The granulations have been exuberant and oedematous and the term required for healing has been prolonged.

In short, this method partakes of many of the drawbacks of the moist dressings, without the advantage possessed by them of perfectly free drainage.

Some years ago, in 1884, while studying the various dressings for granulating wounds in the hospital, I used, among others, oily dressings.

Carbolic oil does not recommend itself to our use, since it possesses all the disadvantages of a carbolized dressing, and it is not aseptic.

The oil that showed the best results was a pure olive oil in which balsam of Peru was dissolved. (This combination, I believe, is still in use for certain cases in some hospitals.)

It had disadvantages, however. It was comparatively a thin fluid, dispersing readily over the surfaces and dressings, and could not be well confined to the wound itself; it appeared to become rancid or undergo a change on standing. It would not take up more than one and a half per cent. of the balsam.

I therefore looked about for some other oil which should combine all the desirable qualities of a dressing for granulating wounds without these drawbacks. And this I found in castor oil.

This oil, being soluble in alcohol, will take up large quantities—fifty per cent. and more—of the balsam of Peru.

It is viscid enough to remain for any length of time in direct contact with the wound, and will remain on those portions of the dressing on which it is originally spread.

It does not, however (if properly applied), prevent the absorbent gauze dressings from taking up blood or secretions from the wound, and does not therefore interfere with drainage. The oily solution saturates the fibers of the gauze, while the aqueous fluids are drawn into the interstices. While, therefore, the wound itself remains moistened by the oil and balsam, it is nevertheless drained of its aqueous moisture.

However much a granulating wound may discharge, it always appears dry and clean when this oily dressing is removed, provided sufficient absorbent material was applied with the dressing, which is an important point.

The oil does not appear to turn rancid when mixed with the balsam of Peru. The mixture will keep any length of time. Bacteriological examinations of the mixture are not, however, complete at this date.

The balsam of Peru is known to be a reliable antiseptic, and is of good service in dressing certain wounds, but it is too irritating to the wounds for general use when used pure, besides being somewhat expensive.

Inoculations made for me from various specimens of Peruvian balsam on agar soils at the New York Polyclinic laboratory failed to produce any cultures of micro-organisms.

As to the castor oil: this can be heated to any degree

deemed necessary; but this must be done previously to the admixture of the balsam. Since this oil comes to us directly from the manufacturers, I have not considered it necessary to subject it to further procedures for sterilizing it, and especially as our knowledge of the sterilization of oils is still somewhat incomplete. To sterilize oil it is necessary to subject it to a temperature of 160° C. for at least two hours. It appears probable, however, that in the balsam solution we have a mild antiseptic mixture, but not one exerting an active antiseptic action on the wounds.

For general use I prefer a four-per-cent. or five-per-cent. solution of the balsam in the oil; but a ten-per-cent. solution occasionally does good service. It is of great importance to use only the best qualities of both the ingredients, as otherwise the product will not be satisfactory. The solution should have a rich, dark-brown color, and be perfectly clear.

No systemic effect of the oil is to be expected, since castor oil does not exhibit any acrid qualities until acted upon by digestive ferments.

I am not aware that this mixture has been used extensively for dressing wounds, although I have myself recommended it in lectures and dispensary instruction very widely and for a number of years.

The method of application of this solution as a dressing is very simple. A bunch of plain or sterilized absorbent gauze is spread with this solution over an area somewhat larger than the wound to be dressed. This is most readily accomplished by the use of a large brush dipped in the solution. The amount applied is graduated according to the size of the dressing and the period during which the dressing is to remain in place. Generally speaking, it is sufficient to have the solution permeate the first four or six layers of gauze. The gauze is now simply laid on the wound, so that the oil comes in contact with it; then a protective layer of rubber tissue or oiled paper is spread over all, and then the bandage applied. I have used this simple dressing in many thousands of cases during the last six years, and have found it very satisfactory for all sorts of granulating wounds, especially contused and lacerated wounds of every description, as well as for burns, furuncles, incised abscesses, etc.

In many cases of sutured wounds it has done excellent service, and it has not interfered in any way with primary union when no infection was present.

For certain cases, however, modifications of this simple dressing are advisable.

In the first place, any of the antiseptic or astringent powders can be first dusted lightly on the wound; the oily dressing over these will prevent the powder forming an eschar or crust, causing retention in the wound. For this purpose I have come to prefer the subiodide of bismuth, although any other powder—iodoform, dermatol, etc.—may be used.

Again, antiseptic gauze may be used instead of the sterilized gauze—and here I have found the dry pyocetanin gauze advantageous. The oily solution does not dissolve the coloring matter, and therefore this is a comparatively clean dressing. If there is much secretion of pus, more

over, the aniline dye is bleached, while the secretions are disinfected. Iodoformized gauze, however, can not be used to good advantage with the balsam oil, because the glycerin in this gauze does not harmonize with the oil.

Iodoform powder, however, may be added to the solution in quantities of two or three per cent., and it will be dissolved and rendered inodorous. (Oleum balsami peruviani ricinatum compositum: Balsam. peru., gr. xx.; iodoformi, gr. x.; olei ricini, ʒj.) The advantages of this method of dressing wounds, then, are the following:

The secretions from the wound are immediately taken up by the absorbent gauze, and thus drainage is established in the tissues surrounding the wound; by removing the secretions from the vicinity of the wound the occurrence of eczematous conditions is prevented.

The formation of epithelium over granulating surfaces progresses more quickly and easily than under any other kind of dressing.

The granulations do not adhere to the dressing, hence the change of dressings is painless and very quickly effected without hemorrhage, and consequently with little danger of reinfecting the wound.

The dressings need not be changed often, twice a week generally sufficing on the average. The wound itself is kept comparatively dry, which checks the proliferation of micro-organisms and the formation of ptomaines in the immediate vicinity of the wound. There is no absorption of the ptomaines, because the secretions on the wound are not under pressure. There is no elevated temperature, as in our dry dressings, on account of the free drainage. There is no irritation of the wound, as is the case in all antiseptic dressings.

On the other hand, however, this dressing is no protection against erysipelas infection of the wound, as the moist sublimate dressing probably is. In this it resembles the iodoformized and bismuth dressings. Furthermore, it is not a proper dressing for eczema or eczematous ulceration, since it does not partake of the character of an ointment.

The dressing does not actively prevent suppuration; it simply drains the wounds and keeps them in a clean condition. And in this it closely resembles our purely aseptic dressings on operative wounds.

We know that wounds made and treated under the aseptic régime (in contradistinction to the antiseptic practice) actually contain larger numbers of micro-organisms than the antiseptically treated wounds do. And yet, notwithstanding this fact, the aseptic wounds give better results. This was proved by Tavel, whose work corroborates that of Welch. Accepting it as a fact that there are micro-organisms present in granulating wounds as well as in the aseptic ones, and pyogenic ones in addition in all cases of suppuration, it is contended that these granulating wounds do better under the oily dressing, by virtue of its better drainage, than they do under antiseptic dressings, which exert an irritative action upon the wound surface.

Since the pathology of the repair of granulating wounds does not essentially differ from that of so-called primary wounds, the difference being more a quantitative than a qualitative one, we may think of using this dressing on

sutured fresh wounds where we expect primary union. In several smaller operations of this kind I have used it with success, it acting very much in the same manner as a simple aseptic dressing. But besides the possible prospect of allowing us to do away with the aseptic fever—which is, in a certain degree, a sort of retention (although a retention of non-septic products)—it offers no advantages over the methods in use at present.

I desire at the present time to recommend the dressing principally for all sorts of granulating wounds as a bland dressing which shall favor epithelial growth and insure drainage without irritation.

TUBO-OVARIOTOMY

AT THE SIXTH MONTH OF PREGNANCY.

RECOVERY.

By D. L. PEEPLES, M.D.,

NAYASOTA, TEXAS.

LUCY S., aged thirty-eight years, the mother of seven children—the last of which was born in September, 1890, about three months after the operation, the history of which is here-with detailed—called to consult me concerning scanty menstruation and a perceptible and continual abdominal enlargement, with pain from time to time, which gradually increased in severity.

The patient stated that she had first observed a slight irregularity of the catamenial periods about two years previously, accompanied occasionally with uneasiness, and finally pain became intensified. A year later irregularity continued, and the menses were accompanied by a disagreeable mucous discharge. At this time the abdomen was considerably enlarged and a hard substance could be detected on introducing the index finger a few inches into the vagina. Neither the patient nor myself entertained any idea of pregnancy. Owing to the severity of the pain, the patient could not attend to her household duties and copulation was prohibited because of the excruciating pain attending it. The mucous discharge somewhat resembled scanty menstruation, although at times it became hæmorrhagic in character.

An examination revealed an ovarian fibroma, and, as the general health of the patient was good, I advised immediate

surgical interference, to which suggestion she readily consented, and after a preliminary course of treatment, in which agents calculated to promote natural action of the excretory organs were used, the operation was done on June 5th, the strictest antiseptic precautions being employed. Anæsthesia having been secured, the abdomen was thoroughly cleansed and washed with a 1-to-2,000 bichloride solution, followed by sulphuric ether.

An incision was made about two inches to the right of the median line, commencing an inch and a half above the symphysis pubis, and carried upward eight inches. It was noticeably surprising to find so thin an abdominal wall as lay over the most prominent portion of the tumor; for not only was the peritonæum exposed, but even before I thought I had reached it it had been divided and I had actually cut into the tumor. Bleeding and capillary oozing were very extensive, notwithstanding the constant use of sponges, the application of catgut ligatures, and the employment of torsion. Upon entering the abdominal cavity I discovered almost unlimited adhesions to the intestines and also a strong attachment to the right anterior superior spinous process of the ilium by a kind of elastic, fibro-cartilaginous substance, which was also attached at about the middle of the crest of the ilium. Both of these attachments were separated by carefully dissecting them away, and the adhesions were gradually and gently ruptured by digital manipulation.

The tumor, which was one of the most vascular I ever saw, was elevated as far as possible and the pedicle ligated in close proximity to the uterus. After removal, and being drained of blood and serum, the tumor weighed four pounds and a half.

The cavity was carefully cleansed with sterilized hot water packs to arrest capillary oozing, and I concluded to risk sponging the bleeding surfaces with a 1-to-3,000 bichloride solution, which were then dusted with iodoform. I was much confused by the still enormous size of the uterus, and my assistants agreed with me in the opinion that there was another tumor *in utero*. As I had not the courage, however, to attempt its removal, the question was left for future consideration. After waiting a few minutes to assure myself that capillary oozing had ceased, the wound was closed without drainage, approximation of the surfaces being secured by deep and superficial sutures, the peritonæum being sutured in conjunction with the abdominal wall. The wound was dusted with iodoform, a strip of bichloride gauze laid on it lengthwise, and over it pads of absorbent cotton, the whole being held in place and the abdominal wall supported by broad strips of adhesive plaster applied crosswise.

The patient having come out of the anæsthesia, morphine and atropine were given hypodermically, and quinine and whisky were administered internally, and she was allowed to rest. Four hours later she was given ten grains of quinine, an ounce of whisky, and ten minims of deodorized tincture of opium, and this treatment was continued with but little variation for eight days, the opiate being occasionally increased as the case demanded. The patient slept during the greater part of this period, being aroused only for the administration of medicine, and food was not given until the eighth day. There was no movement of the bowels for seven or eight days; no vomiting of any consequence; no tympanites; the fever was of a slight character; and there were no indications for drainage.

Stitches were removed from time to time according to the exigency of the case; there was no suppuration externally, and the wound healed beautifully and almost entirely by adhesion. Dressings were made as often as requisite. The bowels were moved by drachm doses of sodium and potassium tartrate given every few hours, and by carefully administered enemata of warm,

soap-water. After the first movement of the bowels they were kept in a lax state, and the quantity of opium was diminished from day to day until it was discontinued. The administration of quinine was finally reduced to three times a day during the last part of the second week, the quantity of whisky was gradually diminished, and its place supplied with soups, broths, etc. The patient began to sit up in two weeks, and walked during the fifth week after operation. In two months she was sufficiently recovered to return to her household duties. In September, 1890, about three months after the removal of the tumor, she gave birth to a stout and robust child, the labor being unaccompanied by any unusual trouble. Soon after confinement she returned to her former work and has since been in perfect health.

I was very ably assisted during the operation by Dr. J. P. Burnett and the late Dr. Harris.

THE DIAGNOSIS OF ENTERIC FEVER.*

By GUSTAVUS ELIOT, A. M., M. D.,

NEW HAVEN, CONN.

RECENT advances† in the treatment of enteric or, as it is more commonly called, typhoid fever give to the diagnosis of the disease increased importance. Medical writers and teachers have generally declared that it is difficult to make the diagnosis of enteric fever until the course of the disease has been watched for five or ten days. Hutchinson says that the diagnosis is always difficult and sometimes impossible during the first week (Pepper's *System of Medicine*, vol. i, p. 311). Practitioners have generally been contented to wait for ten or fifteen or even more days before deciding upon the nature of the complaint from which their unfortunate patient has been suffering. The sick man, of course, has been anxious all the time to know the name of his ailment, and has been deluded by being told that he had some other less serious disease. If at length the physician has become convinced that his patient really has enteric fever, he has calmly declared to the sick man or his friends that the disease has run into typhoid fever.

In many cases, unquestionably, the patient has passed through the course of typhoid fever, and has recovered or died without the physician in attendance having ever learned or declared the true nature of the disease. On the other hand, many patients have died, and their friends have been told that the cause of death was typhoid fever, when in reality the patients did not have that disease, but died of some other entirely different disorder.

The object of this dissertation is to inquire if the early diagnosis of typhoid fever is as difficult as it has been represented to be; what symptoms are most characteristic of it; what diseases it is liable to be mistaken for, as well as what diseases are liable to be mistaken for it; and how it can be distinguished from these other diseases.

The symptoms upon which we have been taught to rely in making a diagnosis of enteric fever are the course of the temperature, the diarrhœa, the character of the diarrhœal

discharges, tenderness and gurgling in the right iliac region, tympanites, and the eruption.

Those which are generally described as most characteristic of the disease are the course of the temperature and the eruption.

Wonderlich, to whom the profession owes such an incalculable debt for popularizing clinical thermometry, in attempting to prove the great usefulness of the thermometer in enteric fever hit wide of the mark. He did not exaggerate in the slightest degree the importance of the thermometer as a guide to the diagnosis and treatment of the disease; but he believed, and distinctly taught, that this instrument furnishes important indications with regard to the diagnosis of the disease, which, I am sure, the experience of each one of you has shown to be fallacious. The schematic diagram, representing the course of the temperature in an imaginary case of enteric fever, which he devised, and which has been reproduced in such recent works as Wilson's *Treatise on the Continued Fevers* (opposite page 156), and Hutchinson's article on Typhoid Fever in Pepper's *System of Medicine* (vol. i, p. 282), has done more than any other one thing to retard the progress of exact knowledge of the disease. His attempt to render our knowledge more exact in this instance has really resulted in making it more inexact.

Experience has proved that, even when the course of the disease is not modified at all by treatment, the temperature does not, as a rule, follow the course of daily morning remissions and gradually increasing evening exacerbations during its first week, which he believed to be typical of the disease. Still less does it do this when, as is usually the case, the course of the fever is more or less modified by powerful therapeutic agents. This peculiar course of the temperature, moreover, even in the exceptional cases in which it is observed, does not become available as an aid to diagnosis until after the patient has been under observation for several days.

The eruption, the value of which is so highly esteemed by many teachers as an aid to diagnosis, does not, as a rule, appear until five or six days have elapsed.

These two diagnostic factors, the course of the temperature and the eruption, not being available as aids to diagnosis—the one until the patient has been under observation for several days, the other until he has been ill for a number of days—it is not strange that the notion has become prevalent that an early diagnosis of the disease is generally difficult and sometimes impossible.

Diarrhœa is not a very reliable symptom upon which to base a diagnosis, because in most cases the patient has taken more or less laxative or cathartic medicine before sending for a physician. On the other hand, in a considerable proportion of cases, especially mild ones, diarrhœa never occurs.

Iliac gurgling is a common phenomenon, and not at all peculiar to enteric fever.

Iliac tenderness, on the other hand, may be very slight, or may be absent altogether.

It is clear, therefore, that it is difficult to make the diagnosis of enteric fever if one relies upon the symptoms which are generally described as of most importance.

* Read at the one hundred and first annual meeting of the Connecticut Medical Society, May 25, 1893.

† See the *New York Medical Journal*, Aug. 6, 1892, vol. lvi, No. 6.

But aside from the intrinsic difficulty of solving some of these diagnostic riddles, it must never be forgotten that one reason why an early correct diagnosis is made so infrequently is because practitioners forget the possibility of the existence of enteric fever. The disease is one which, it seems almost superfluous to remind you, commences, as a rule, very insidiously. I once saw a young woman taken with a severe epileptiform convulsion who a few hours later had a temperature of 104°. Careful inquiry failed to elicit any previous symptom of ill health. She died after a few days, and on post mortem examination the extensive ulceration of Peyer's patches with enlargement of the mesenteric glands left no doubt in any one's mind that she died of enteric fever.

Such cases are, however, very exceptional. Generally the patient has been feeling indisposed for several days, and perhaps has taken a few doses of some domestic or popular remedy. He may then present himself in the physician's office, and remark in an offhand way, as he enters the consulting room: "I am having a little malaria, and I want you to fix me up so that I will not have to stop work, for I am very busy just now." It happens not infrequently, it is painful to confess, that the physician falls into the trap thus unintentionally set for him, and, without making a thorough examination of his patient, forgetting the possibility of the existence of a more serious disease, declares with easy grace that the case is one of malaria or biliousness—terms used by successive generations of practitioners as a cloak beneath which to hide their careless observations and their pathological ignorance.

If, now, such a patient is really suffering from typhoid fever, as proved by the subsequent development of the symptoms, even if the disease is still in its early stages, careful inquiry will, in nearly every case, reveal the presence of a group of symptoms which, taken together, point very strongly to the existence of that disease, and in many cases warrant one in making a positive diagnosis the first time the patient is seen.

The great trouble is that many physicians do not seem to consider the possibility of the patient's having typhoid fever until he has had successive intestinal hæmorrhages, or his hair has commenced to drop out. It is my firm conviction that every careful practitioner who treats a case of typhoid fever ought at least to have suspected the existence of that disease the very first time he sees the patient, and that not to have considered the possibility of the presence of that disease is an evidence of carelessness closely bordering on criminality.

Let me repeat again that the reason why so many men fail to make an early diagnosis of typhoid fever is not that it is a difficult thing to do, but because they neglect to consider the possible presence of that disease.

Generally, the first, and by far the most common, symptom of which patients in the early stage of typhoid fever complain is headache. When the physician is first consulted, the headache, having come on rather gradually, has generally lasted several days, and has been almost constant. It may have been of either moderate or great severity. This gradual, insidious onset of the symptoms has

given rise to the statement in the text-books that it is generally impossible to fix definitely the beginning of the disease. My experience has taught me that this teaching is erroneous. Although at first the patient declares that he has been sick several days or about a week, it generally is perfectly possible, if he is moderately intelligent and is seen fairly early in the course of the disease, by careful inquiry, to fix upon one particular day on which he began to suffer from headache and perhaps also from chilly sensations, and before which he was in his usual health. Whenever a patient complains of headache which has lasted several days, the physician should always satisfy himself that the patient has not typhoid fever before concluding his examination.

No one ought ever to prescribe for a patient without inquiring in regard to the existence of headache. Consequently, unless headache is really absent in any particular case, and it very rarely is, there is no excuse for overlooking the possibility of the existence of enteric fever.

If this symptom is present, the next thing to do is to count the pulse. This will generally be found to be accelerated. I do not recollect that I have ever seen a patient at the commencement of enteric fever who had a pulse of 72 or lower. If protracted headache and acceleration of pulse are both present, one must next take the temperature. This should never be omitted in any case where there is headache and accelerated pulse.

If there is elevation of temperature and acceleration of pulse with headache which has lasted several days, the probability that the patient has enteric fever is very strong.

Inquire next if he has had chilly feelings—which I remember to have heard the late Dr. Alonzo Clark, of New York, call diluted chills—not repeated at regular intervals on successive days, but occurring frequently and irregularly for several days. These are very different from the chills which occur in the course of malarial affections, and are strong corroborative evidence of the existence of enteric fever.

Nosebleed is an occasional early symptom. Its presence is confirmatory evidence, but its absence is so common that little significance can be attached to the fact that it has not been noticed.

If no laxative or cathartic has been taken and there is diarrhœa, the movements being soft in consistence and of a yellowish color, we have additional evidence that the disease is typhoid fever. If cathartics have been taken, the diagnostic value of the symptom—looseness of the bowels—is greatly lessened. On the other hand, even when enteric fever exists, it frequently happens that there is no diarrhœa.

These half dozen symptoms are the early symptoms of greatest diagnostic importance.

To make the argument complete let us look for a moment at the other side. If the patient who is sick has not had headache there is very little probability that he has enteric fever. If his pulse is 72 or less, one would seldom be mistaken in declaring that the disease is not typhoid fever. Similarly, if the temperature—no antipyretic measure having been adopted—is below 99° F., one would

hardly be justified in thinking that his patient has enteric fever.

In the absence of all of these symptoms—namely, headache, quickened pulse, and elevated temperature—one need not hesitate to assure a patient that he has not enteric fever.

If, on the other hand, these are present, the probability is considerable that the disease is enteric fever, and this probability is increased if there is obtained a history of chilly sensations frequently repeated for several days, of repeated epistaxis, and of diarrhœa. Iliac gurgling and tenderness are also corroborative symptoms, which should always be looked for, and, if present, strengthen the diagnosis.

Turning now to still another side of this subject, the question is naturally suggested, What diseases are likely to be and what actually are mistaken for typhoid fever, and under what circumstances is an erroneous diagnosis of typhoid fever made?

When typhoid fever really exists, but is not correctly diagnosed, it is in this vicinity most frequently called malarial fever and at a later stage typho-malarial fever. This mistake generally depends upon a mixture of ignorance and carelessness. I do not care to attempt to maintain at the present time that typho-malarial fever never occurs. I presume that every one is aware that this term should, however, be strictly limited to cases of disease which are due to the simultaneous action of the typhoid and of the malarial poison. It is my firm conviction that most cases of so-called typho-malarial fever are in reality cases of typhoid fever. If a malarial element is present in some of them it is possible to remove it promptly by appropriate treatment. With regard to cases of so-called malarial fever it should be remembered that most fevers which are caused by malarial poison are of a distinctly intermittent or remittent type. If, therefore, a case of continuous fever occurs, which is uninfluenced by adequate doses of the ordinarily used antiperiodics, there is good reason for challenging the diagnostic accuracy of any one who pronounces such a case malarial fever. In most cases of this kind the disease is enteric fever. Bilious fever is another term which is still occasionally heard, chiefly among men whose acquaintance with medical literature has not extended to publications of recent years. I believe that it is generally recognized by practitioners who are familiar with modern medical literature that there is no pathological or clinical foundation for recognizing any form of disease as a distinct entity under this name.

The vital statistics of our city and State show a number of deaths reported as due to malarial and typho-malarial fevers which is almost equal to the mortality reported from typhoid fever. There is little doubt that the majority of these reported cases represent mistakes in diagnosis, where enteric fever has been overlooked and called by another name.

The diseases which a careful practitioner will bear in mind when he makes the diagnosis of enteric fever are intermittent fever, remittent fever, and acute catarrhal inflammation of the respiratory organs. In some cases it is

impossible to make an absolutely certain diagnosis the first time the patient is seen. All three of these conditions may be accompanied by chills, by acceleration of the pulse, by elevation of the temperature, and by headache. In intermittent fever the complete subsidence of the fever in the interval between the paroxysms quickly settles the doubt, which may have existed if the patient had been feeling in poor health before the occurrence of the paroxysm, if the chill had been slight, and if the pulse was rapid and weak. In remittent fever the recurrence of chills at tolerably regular intervals, the lower rate of cardiac pulsation with less diminution of its force, the profuse perspiration, the prompt and favorable influence of adequate antiperiodic medication, and the absence of abdominal symptoms, will generally enable one who takes an unprejudiced view of the case to come to an early decision as to the nature of his patient's malady.

Quite as puzzling as any others are the cases in which the patient has, as we are accustomed to say, taken cold, and in consequence has suffered for several days with headache and anorexia, has perhaps taken one or several doses of cathartic pills so that he has had pains in his abdomen and looseness of the bowels, and at the time when he is examined has some elevation of temperature and somewhat quickened action of the heart. Time is an important aid to the diagnosis of these cases, which generally improve rapidly under appropriate treatment, while in cases of typhoid fever the symptoms do not improve, but, on the contrary, particularly if expectant treatment is followed, generally grow worse.

Turning, now, to another side of the subject, what diseases are erroneously called typhoid fever?

I recollect that a man past middle life consulted me as an office patient a few times, in whose chest I discovered phthisical consolidation of a large part of the upper lobe of one lung. He died a few months later under the care of a practitioner of long and extensive experience. The son of the deceased subsequently told me that the doctor said that his father had typhoid fever. Now, perhaps that doctor and the relatives of his patient believed that the man actually had typhoid fever; but I did not, for I knew that the man had consumption, and that it would almost certainly kill him in the course of a few months, as it undoubtedly did. But cases of chronic consumption are not nearly as likely to be mistaken for typhoid fever as those of acute tuberculosis. Some of these cases are very difficult to distinguish from typhoid fever. Their onset, however, is generally distinctly more gradual and indefinite; the headache is a less striking symptom, the abdominal symptoms are less clearly defined, the thoracic symptoms are more marked, the daily variations of temperature are less regular and more extensive, and sweating is more common and more profuse.

Now and then we hear of some woman whose death is alleged to have been caused by typhoid fever, or even by typho-malarial fever, who had a baby two or three weeks before she died. Now, without presuming to deny absolutely the possibility of this sequence of events, when you and I read or hear of such a case we do not believe that

the woman really had typhoid fever. Most of us, I think, feel pretty confident that the woman died of puerperal septicæmia.

In any case, when the patient has a high temperature and a quick, feeble pulse, the single fact that the patient has been confined a few days previously ought to lead the physician to doubt very strongly the existence of enteric fever.

Acute ulcerative endocarditis might perhaps be mistaken for typhoid fever. The petechial eruption of the former is, however, entirely different from the roseolar papules of the latter. The temperature of the former is more erratic, and the endocardial friction sounds, which are so constant in the former, are exceptional and accidental in the latter.

Typhus fever is so very rarely seen here that it is scarcely necessary to mention the great stupidity or hebetude (as the books call it), the flushed and congested cheeks, and the petechial eruption so characteristic of this disease.

Septicæmia and pyæmia might be mistaken for typhoid fever, but generally careful examination will reveal some adequate cause for these disorders. In addition, the wide daily range of temperature, the profuse perspiration, and the great prostration are sufficiently distinctive to remove doubt.

What has been said has had reference chiefly to the early diagnosis of enteric fever. A few words of the later symptoms.

The eruption is not infrequently present when the patient first consults his physician. If not, it generally appears in three or four days, and is then an important aid to diagnosis. The more a man looks for it and the more he becomes accustomed to it, the more valuable information it gives him.

Recurrent intestinal hæmorrhages constitute another aid to diagnosis late in the course of the disease. Many, I fancy, would feel inclined to question the accuracy of a diagnosis of inflammation of the bowels if the patient died in three or four weeks of recurrent hæmorrhages from the bowels.

The occurrence of sudamina during the later stages of the disease and the falling out of the hair during convalescence are occasionally of interest as affording some confirmation of a diagnosis made several weeks before.

I will not trespass longer upon your time to discuss further the individual symptoms of the disease or to enumerate and differentiate the different local diseases which, through carelessness, might be overlooked. It should be a matter of routine to exclude disease of each individual organ before deciding that the patient is suffering from any general or infectious disease.

Fewer mistakes in diagnosis would be made and better results in treatment would be obtained if every practitioner would bear in mind the following rules:

1. Never prescribe for a patient until you have counted his pulse and asked him if he has a headache.
2. If he has a headache and his pulse is above 72, never omit to take his temperature.

3. If his temperature is elevated, his pulse accelerated, and his head aching, never forget to ask yourself if he has typhoid fever.

4. Do not postpone making your diagnosis until the patient has been sick two or three weeks. Make it the first time you see him, or at least at the very earliest possible moment.

MANAGEMENT OF DAMAGED INTESTINE IN STRANGULATED HERNIA.*

By H. HORACE GRANT, A.M., M.D.,

PROFESSOR OF SURGERY IN THE HOSPITAL COLLEGE OF MEDICINE, LOUISVILLE.

WITH reference to taxis in strangulated hernia I take it to be pretty well settled, in view of the safety of present surgery and the satisfactory results of recent operations for radical cure, that the theoretical treatment of all hernias, certainly strangulated, should be operative. The various accidents and dangers of returning uninspected an intestine subjected for an uncertain period to an unascertainable degree of constriction, and to an often unknown amount of manipulation, do not need recalling. Practically, however, such treatment is not always applicable. Still, it is not extreme to say that all hernias certainly strangulated twenty-four hours even without vomiting; all hernias certainly strangulated, in which vomiting comes on late after pain and obstruction, as indicating constitutional rather than local influences; all strangulated hernias in which vomiting has occurred, that have been manipulated; and all strangulated hernias in which the symptoms of collapse are appearing, should receive operative treatment at once.

In recent hernias in all situations, and particularly the femoral, this obligation is even more imperative.

To be practical, there arise at the operating table two sets of questions: First, Have we a dangerously damaged gut? Second, If the gut is dangerously damaged, shall we temporize, make an artificial anus, or resect?

As to the first question there must always be uncertainty, but that uncertainty involves great danger. Treves, in his late work on *Operative Surgery*, page 523, recommends that the "doubtful bowel" be returned to the peritoneal cavity. Whenever there is enough doubt about the condition of the gut to be termed "doubtful," I am convinced it should receive different treatment altogether. It is impossible to decide in some instances by either the appearance of the gut, the duration and tightness of the constriction, the history as to vomiting, or the constitutional condition, whether the gut will recover, nor is the apparent restoration of color and circulation always a reliable guide.

Superficially the color may appear normal while necrosis has already begun in the deeper tissues. I offer an illustrative case:

CASE I.—A man, aged thirty-four; admitted to the City Hospital February 18, 1893, at 12 M., with a large tumor of the scrotum. From the patient it was learned that the hernia was an old one, never before strangulated, had been down four days,

* Read before the Kentucky State Medical Society, at Frankfort, Ky., May 11, 1893.

taxis had been done outside the hospital by two physicians without result, no action from the bowels for four days, pain inconsiderable, and no vomiting. There was no impulse on coughing; taxis by the house surgeon was without effect, and hot applications were made.

During the night the patient vomited two or three times and complained of pain. I saw him at 10 A. M. on the 19th. A tumor of the size of a small coconut was found; normal temperature; pulse, 80. Immediate operation, without taxis. The sac, somewhat discolored, was filled with a dark-red serum. The colon, vermiform appendix, and ileocaecal valve presented. The constriction was very tight, the bowel greatly discolored, and presented on the colon two black patches each of the size of a dollar. The constriction was divided and the mass covered with cloths wrung out of hot water changed every five minutes for an hour.

At this time the normal color had almost perfectly returned, the black discoloration was quite gone, and the circulation seemed fully re-established. Under chloroform the constriction was freely divided and the tumor returned carefully, a drainage-tube put in, and the wound left open. General peritonitis developed on the third day, and at the autopsy Dr. Rodman and I found the whole mass in an inflamed condition, with two spots ready to slough, but no perforation. To have made an artificial anus or to have done a resection would, in this case, have involved removal of the head of the colon, and the formidable operation was not to be undertaken in the surroundings.

Plainly the danger of septic peritonitis is almost as great as that of perforation, and so long as any question of the vitality and aseptic condition of the viscera remains, it should be kept out of the peritoneal cavity. If the gangrenous portion is omentum and can be cut away, the danger is thus removed.

CASE II.—March 14, 1893, I saw with Dr. Cochran and Dr. Kelly, of Louisville, Mrs. K., aged forty-two; she had a tumor in the right groin which had been irreducible for two years, but she had been suffering for two days with pain, intestinal obstruction, and occasional vomiting; the pain was severe. No more taxis was made than to verify the diagnosis. Immediate operation. Sac at femoral opening was filled with dark-red fluid and an omental tumor as large as the thumb, two inches and a half long, and becoming gangrenous and adherent. This was drawn out and tied off, and a healthy-looking bowel seen in the bottom of the wound. The omental stump was stitched to the ring at the bottom of the wound, which was closed up without drain. Recovery without temperature or any sign of suppuration.

It appears that in these two cases strangulation and gangrene existed without much constitutional disturbance, and in the first the return of color was not a safe guide to the future treatment.

In future I shall return to the cavity only such of its contents as I am sure are living and aseptic. A little later a plan will be discussed for the treatment of doubtful intestine.

For the second practical consideration three plans of treatment are open: The temporizing, which should consist in free division of the constriction, excision of all septic-looking peritonæum, and the withdrawal of the intestine until sound tissue appears, when the bowel should be sutured through its outer layers to the abdominal wound, cov-

ered with iodoform gauze, and watched for two or three days, if necessary, to be safe. This method was first suggested by Rovsing and Graefe. If the bowel recovers, it is, of course, returned; if not, resection is done or an artificial anus is made.

With respect to the artificial anus it is always to be remembered that such a step is usually but preliminary to an always dangerous and difficult one of restoration of the continuity afterward, and is therefore only to be commended in an extremity.

Treves (*op. cit.*, page 524) advises, in making an "anus præternaturalis," that the stricture be left undivided, lest the protective adhesions be destroyed. Such a course must be unsafe in the extreme.

Lockwood* reports thirty-seven cases of artificial anus made in St. Bartholomew's Hospital, London, in which a free incision was made into the tumor without the removal of the diseased tissues, and usually without division of the stricture. Of these thirty-two, or 88.57 per cent., died, presumably from arrested peristalsis and septic infection.

The method suggested by Poulsen† is perhaps the best. He opens and irrigates the sac, divides the stricture, draws out sound bowel and fastens by sutures, as in Rovsing's operation.

When perforation occurs, the open end is closed with Péan's forceps and kept protected with gauze; after a few days the protrusion is destroyed by thermocautery or scissors, and the enterotome is used to divide spur after Dupuytren's method. Poulsen reports three recoveries and two deaths by this method—a not very encouraging report.

It is found, after the incision of a gangrenous tumor and the establishment of the artificial anus, that though there is a free escape of fecal matter, the pain and vomiting are not always relieved.

This is due to interrupted peristalsis in the upper part of the intestines and to beginning sepsis. If, however, the constriction is freely divided and all dead tissues are removed, the wound irrigated and made clean with gauze packing, the symptoms are usually relieved, even if fatal issue comes later.

CASE III.—In December, 1891, I saw Mrs. C., aged seventy-four; small femoral hernia, strangulated three days, with usual symptoms. The sac was found gangrenous as well as the bowel. No separation of adhesions was made, and the bowel was not drawn out. Free discharge of fecal matter took place, but the patient continued to vomit occasionally, as well as to suffer some pain, and died on the fifth day after the operation, of exhaustion.

CASE IV.—I saw at 6 A. M., March 16th, Mr. G., of Middletown, Ky., who had been suffering from constipation and nausea, with some abdominal pain, for three days, but continued about the house. On the afternoon of the 15th he took a dose of salts. During the night he was attacked with vomiting and very severe abdominal pains. He summoned at midnight a doctor, who found a tumor in the right groin about the size of a hen egg; no taxis was made, but hot applications and opium were ordered.

* *Proceedings of the Royal Medical and Chirurgical Society*, 1891.

† *Annals of Surgery*, January, 1891.

I saw him at 6 A. M. The tumor was an old femoral hernia, usually reducible, for which no truss had ever been worn; it was tightly strangulated and had been irreducible for three days. The patient was asleep and had not vomited in four hours; pulse, 72; temperature, 98°. Immediate operation. Sac was filled with dark-red serum which spurted out on section; sac was gangrenous and the bowel sphacelated and offensive. Two inches were drawn out and healthy gut was sutured through serous membrane only to the healthy wound above the gangrene, then the bowel was split open. The patient recovered well from the operation without fever or pain, though he died from acute mania and voluntary starvation in the sixth week.

The third method of treatment, or resection, is of course the ideal treatment, when the consideration of the patient and surroundings permit. In his abstract, above referred to, Lockwood arrives at a conclusion, from statistics, in favor of resection.

I have collected from the current literature of 1892, 1893, and private communication, reports of seventy-one cases of gangrenous hernia operated on in the three ways. The St. Bartholomew's Hospital cases are not included in these statistics. In fifteen of these cases an artificial anus was made, with five recoveries and ten deaths; in nine cases the temporizing method was employed, with subsequent return of the gut, four recoveries and five deaths, one of the patients who recovered having fecal fistula; of the forty-seven resections, twenty-two recoveries and twenty-five deaths. Thus we have for artificial anus five recoveries and ten deaths, or thirty-three and a third per cent.; return of bowel after it looked safe, four recoveries and five deaths, or forty-four per cent.; resection, twenty-two recoveries and twenty-five deaths, or forty-seven per cent.

Of course these statistics are less valuable from the fact that many deaths from each method are not reported, and the doubtful successes from the first two methods are often left unpublished. But the resection statistics are of special value, as the work was done by a few operators—all skilled surgeons—and most likely represent all their work at that date. The above tables of reference are submitted.

These forty-seven resections were done by eight operators and indicate that under favorable surroundings surgical skill can do even more by the ideal method than by temporizing or compromising.

The various methods of resection can not be discussed here.

I present to your inspection the clamp I have before described. With it I am able to make the resection in experimental cases in fifteen minutes. I have not yet perfected the mechanism of the instrument.

I conclude, from the review of the subject: 1. All doubtful gut should be kept out until the question is settled, for two or three days if necessary, under inspection. 2. That when the surroundings are favorable, the experienced surgeon should resect the gangrenous gut, and after thorough antiseptic irrigation make immediate suture, unless the patient be very old, feeble, or in collapse. 3. That when the surroundings are not favorable, nor convenience and experience at hand, the dead tissues should be cut away, thoroughly irrigated, healthy gut drawn out and sutured and packed with gauze, with the view of closing the fecal fistula after two or three weeks.

SOME NEW FEATURES IN THE ETIOLOGY AND TREATMENT OF CHOLERA INFANTUM.*

By J. F. CHMELICEK, M. D.,
DETROIT.

It has been my happy lot to practice medicine among the population occupying the tenement houses of New York for the past three years. I call it a happy lot, first, because it has given me the opportunity to treat more cases of cholera infantum, or so-called summer complaint, than all the other diseases of children put together; second, because it is the best field for young physicians open for observation, and there are unique cases that can not be found in clinics or dispensaries, as you come in direct contact with the most unhygienic and unsanitary surroundings, and in direct contact with the bare truth. I do not need to go into a long and time-absorbing description of those large tenement houses, with which everybody is more or less familiar, but I will describe the one I have connected with my observation, and will mention it with the first case that came under my treatment.

It was in the latter part of June of 1890 when I was aroused one morning to hurry down to see a patient in East Seventy-third street, who was suddenly taken sick after a very warm, sultry

* Read before the Detroit Medical and Literary Association, June 19, 1893.

night. Walking alongside of big tenement houses, I came to the number indicated in the message. I noticed a great display of meat before a butcher shop that was located in the same house, a grocery store next to this, and a saloon on the corner, an Italian fruit stand completing the quartette. Upon entering the hall, I almost fainted with the terrible smell of half-decomposed meat being boiled in the back room of the butcher shop, from which all the vapors entered the hall and ascended to the upper floors. Before I reached the top floor I perspired freely, and had to gasp for fresh air. The house was fully occupied by sixteen families, numbering in all eighty-two persons, forty-two of whom were children, and of this fully half below five years. Every door was open, but the windows leading to the dark air shaft were closed to avoid the draft, as I found out later. The door leading directly into the kitchen of the apartment to which I was directed was also open, and passing through I came in contact with my patient lying on a lounge in the front room, of which the windows were tightly closed; immediately I opened the windows, but the rush of the foul air from the floors below made such a terrible draft that I ordered the door leading into the hall to be closed. The heat from the stove and radiating from the roof (this being on the top floor) made the room as hot as a furnace. After getting the history and making the examination of the child I made the simple diagnosis of cholera infantum, and sat down to the table to prescribe.

There was such a buzzing of flies leaving the oilcloth-covered table as I had never seen before, and, on my mentioning this fact to the people, I was told they were lucky, for the people down below had the ceiling almost black with them, of the truth of which I had plenty of opportunity to satisfy myself later on. At that time I did not pay any more attention to it, the child being fed at the table and being in dentition. I ordered a general bath lasting five minutes, with friction, then cut off all food supply except milk with limewater prepared according to Dr. W. H. Thomson's formula—viz., cream, half an ounce; milk, two ounces; linewater, two ounces; sugar of milk, one drachm—and, prescribing powders of calomel well triturated with saccharum lactis, left and promised to call the next morning. The same day, about three o'clock P. M., I was hurriedly summoned to see my patient, as he was in convulsions, with high fever. I immediately departed for the house, ordered mustard poultices to be applied to the abdomen, and myself prepared a bath, finding the convulsions due to some intestinal irritation. The child soon rallied, but the people insisted on giving some other medicine, the powders having caused more vomiting.

I gave the common chalk mixture with an addition of bismuth, and inquired if the child had been fed as I had ordered. I was told it was, except that instead of using milk sugar they used a teaspoonful of common sugar from the bowl standing on the table; out of mere curiosity or impulse, I looked in, but I can not describe my surprise at finding the sugar covered with a black, crawling mass of flies, and having the appearance of raisins more than sugar; and on driving them away and examining it I found the side of the bowl covered with the excreta of the flies, also making the granules appear almost gray. My suspicion was aroused, and on looking around I found a piece of soiled linen thrown carelessly in the corner of the kitchen, also vomited matter on the floor, covered with flies. Before leaving I received an invitation to call on the floor below and see another patient, a girl of eight months with the first dentition; child feeble, being fed on bottle since four months old; people used condensed milk diluted with water drawn directly from the pipe; they also gave brandy in sweetened water, as they had lost one child a year before, and had been told to do so by the former physician the child took on an average from two to three table-

spoonfuls of brandy in water a day, its thirst being immense; this naturally required the addition of sugar, which was exposed as carelessly as with the former case in an open receptacle for the benefit of the flies in another room. After I left the room I went home, and being at the time a recent graduate, I took out some books and informed myself on the subject thoroughly, but not to my satisfaction, as I have not found in the leading text-books any mention made of the etiology having any connection with the use of sugar, or of flies acting as carriers of the infection in coming and going from the soiled floor and linen into the sugar receptacle, and conversely, depositing feces on the food to be consumed. The night following I was called to attend two more children in other parts of the city, but, the next day being very sultry, the increase in the little patients was enormous, three more being in the house adjoining the one mentioned above, and one more in the same house; this was on June 26th. All of these children were taken sick suddenly and all were fed more or less on artificial food; many of them were given sweetened water with different flavors, but mostly brandy; also watermelons bought from the Italian fruit-dealer on the corner. Vomiting and purging were predominating in those who were not teething; fever, colicky pains, and convulsions in those who were teething. After carefully examining and comparing the facts I came to the conclusion that there existed a direct proportion between the number of flies in the rooms, the amount of sugar consumed, and the cleanliness of the parents; also the existence of raw meat in the immediate neighborhood. That after removing the child from the house and giving him nothing but cold limewater sweetened with a little glycerin, the child got better in a few days. I regarded medicine containing sugar as doing more harm than good, and endeavored to impress my patients' parents with the idea that leaving the child twenty-four or forty-eight hours without food would not starve it, but feeding it with polluted sugar water, or sweetened milk, with the sugar used from the receptacles exposed to the flies, would be certain death. During the summer I treated fifty-six cases with but two deaths, my favorite prescription being one of these: During severe vomiting, spir. amon. arom., gtt. j; glycerin, gtt. x; aquæ calcis, 4 c. c.; dose, 4 c. c. every hour or two. Along with this I ordered two baths of five minutes' duration daily, and nothing but pure boiled milk, mixed with equal portions of limewater, and kept on ice or in a tightly corked bottle until used. I fed my pug dog on milk sweetened with the sugar obtained from one of these houses, with the result of giving him diarrhoea. During the winter I had experimented with unslaked lime and glycerin water, and found out that five per cent. of glycerin added to boiled water would dissolve twice as much of lime as pure water would. This solution, then, added to boiled milk will keep it indefinitely if tightly corked, and even if exposed to the atmosphere it keeps it some time without giving acid reaction. The next summer of 1891 I started out to treat my first case of cholera infantum with nothing but freshly boiled milk, to which I added the above-described solution, and paying more attention to the mothers than to the children and instructing them how to keep their children healthy without filling their stomachs with brandy and paregoric.

I gave solution, in proportion of two ounces to eight ounces of milk, and in extreme prostration I gave five drops of brandy in five per cent. of glycerin and limewater. This proved sufficient in my hands. I disposed of twenty-three cases (I left for Europe in August) without a single death. The summer of 1892 was passed with thirty-eight cases; one death due to oedema of the lungs. My suspicion as to the probable cause was very well illustrated during the last summer. I was called to see two patients in one house on Avenue A, just off

the horse market, where a horse had been killed and left lying for days previously; the cases were both on the ground floor (this is considered fortunate for a New York physician) and the rooms were filled with flies. As I came prior to my promise, the mother of one of the children had taken her baby down to the river front two blocks below, and while I had to wait I noticed the flies coming and going directly to the dead horse, exposed to the hot sun's rays, and on the mantelpiece there was a bottle containing some mixture around which flies swarmed, and it occurred to me that the mother was feeding her little one on so much dejecta washed from the mouth of the bottle at regular intervals. The child got well on withdrawal of all medicines. The adjoining houses were full of little patients treated by other physicians.

Without going further, I sum up and say that there is good reason to believe that cholera infantum is due to direct infection, which is propagated by flies, sugar, and fruits as a medium, and is aggravated by improper feeding, hot weather, and exhausting diseases, such as dentition, malarial disease, and rickets. Its treatment should be confined mostly to improvement of the surroundings, teaching the mother the simplest rules of hygiene and how to prepare cow's milk, and cut off all supply of sugar and substitute glycerin in its place. I come now before you, gentlemen, with the plea that you give to the paper your kind consideration and the treatment a fair trial, and those who have more facilities also strict investigation as to the bacteriological question. The record of one hundred and seventeen cases treated in the same manner with but three deaths, with hardly any medication, should also be accounted for. The bath I use is of 85° F., lowered with a few pints of cold water to 65°, while the patient is in the bath tub, and friction is given. In very extreme cases I have withdrawn food for forty-eight hours, giving nothing but glycerin and limewater in teaspoonful doses, with a few drops of brandy in those passing the acute form. The amount of milk I limit to one pint or less in twenty-four hours throughout the illness. The average age of my patients was eleven months and three weeks. I wish to impress the reader with the fact that I have described cases of cholera infantum, and not cholera morbus, as he may think. (See below.)

NOTE.—After I had furnished my paper, which I thought to be original, I read in the *New York Medical Journal* of the 3d inst. the communication of Dr. Savtshalk, of Russia, who has experimented on the capability of flies carrying the microbe of cholera. He fed flies on broth containing cholera dejecta and found that for a considerable time thereafter the flies expelled faeces loaded with active cholera microbes. I was also unaware of the present Surgeon-General Sternberg's recent remarks before the New York Academy of Medicine, in which he is reported to have said that his own experience had led him to look upon the fly as a veritable cholera-infection carrier. I am pleased that such eminent observers have come to the same view to which I was led spontaneously three years ago.

485 BEAULIEU STREET.

The Death of Dr. John Rae, the famous Arctic explorer, is reported as having taken place at his home, in London, on Monday, the 24th inst.

NITROGLYCERIN HYPODERMICALLY FOR THE RELIEF OF THE EPILEPTIC PAROXYSM.

By H. ELLIOTT BATES, M. D.,

POUGHKEEPSIE, N. Y.

THE beneficial results which follow the administration of nitroglycerin in angina pectoris, and the rapid relief of those headaches accompanied by small, wiry pulse, pallor of the face, and sudden faintness, and often the relief of a severe neuralgia, led to the question, Can nitroglycerin be utilized to relieve the arterial spasm of the epileptic attack, thereby to establish consciousness, relieve the convulsive movements, prevent the after-exhaustion, and to prevent as far as possible the effects of the anæmia of the brain?

The use of this drug and nitrite of amyl has long been advocated at the beginning of an attack as soon as the least suspicion of an aura arises—i. e., to abort the attack—but its use after the attack has been established, when the sufferer lies where he has fallen, with rigid limbs and unconscious of all surroundings, has not been advocated to my knowledge. Obviously it called for the employment of the hypodermic method of medication and it was given a trial.

In the first case the patient had had attacks for four years. At this time he lay as he had fallen, rigid and totally unconscious, with violent muscular convulsions, foam about the mouth, and all the other symptoms of an epileptic seizure. A hypodermic injection of one one-hundredth of a grain of nitroglycerin was given, and before the needle could be withdrawn total relaxation took place, consciousness returned, and the patient called for a drink of water.

Another case was seen in a severe convulsive seizure. The history was given of frequent attacks of the grand mal, with a distinct aura, and the attack followed by malaise and exhaustion which lasted for several days.

Here the administration of the drug was followed by speedy and very satisfactory results.

In a third case, seen four times, the method has proved of great value, as the patient while in the attack is very violent—an object of terror to his family and the neighborhood. The use of the drug was followed by a prompt return to consciousness. The method has been tried in twelve cases in all without a failure. Once a second dose of one one-hundredth of a grain was required, but that was entirely successful.

The number of cases is small, but *non numerandæ, sed perpendendæ observationes*.

In all the cases the after-effects of the attack were markedly lessened, the patients recovered without the fatigue and general demoralization, and the sudden transition from an object of terror to a rational being has been of considerable value to patient and physician. It is not claimed for the method that it is curative. It does shorten the attack, saves fatigue, and I believe has some influence upon the frequency of the attacks. The after-treatment consists of the administration of the bromides in a bitter infusion, hops being preferred, and the use of minute doses of nitroglycerin.

This paper is written in the hope that the method will be given a trial, and that it may prove of some use to the physician in treating what is usually an urgent condition.

THE
NEW YORK MEDICAL JOURNAL,
A Weekly Review of Medicine.

Published by
 D. APPLETON & Co.

Edited by
 FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, JULY 29, 1893.

A HOUSE DIVIDED AGAINST ITSELF.

It is unfortunate that the interests of the medical profession of the United States are so varied that each year the possibility of securing harmonious action which will tend to the general advancement of the profession's influence and interests seems to be more and more remote.

Dr. J. C. Culbertson, in his valedictory article as editor of the *Journal of the American Medical Association*, called attention to the fact that that association was not holding its own, and added that, unless action that would modify a number of the by-laws was taken, there was imminent danger of its disintegration and of the formation of another body of national character that would attempt to do the work that it ought to accomplish.

Recent years have witnessed the multiplication of societies of specialists until to-day there appears to be no specialty that is not represented by at least one national society. For some specialties there are two societies in existence. The work of these societies of specialists is very unequal, a few good papers being presented, together with a number of mediocre essays.

Some of these special societies, such as the American Ophthalmological Association, keep a sharp watch that their fellows shall not injure the dignity of their position, and unprofessional conduct is visited by expulsion.

Mr. Ernest Hart, who, as the editor of the *British Medical Journal*, has had ample opportunity to become acquainted with the various factors contributing to the success of a national medical association, has recently been in this country as the guest of the American Medical Association. He contributes to his journal for July 15th some of his impressions of the medical profession in America. He refers to New York, with its wealth of clinical material, its largely developed hospitals and schools, its prosperous practitioners and consultants, and its reputed assumption of a certain leadership that some think too self-confident, with its roots not yet deeply set. It is to be deplored that the New York physicians are so unfortunate as to have given this impression—one that is not, it will be admitted, original with Mr. Hart, but one that we have heard from the graduates of our medical colleges, from the physicians that attend our post-graduate courses, and from the physicians of the South and the West that come in contact with New York practitioners. While it can not be admitted that New York physicians, as a rule, assume a superiority and importance that neither their personal qualifications nor the sum-total of New York's contributions to medical science justify, it can not be denied that some of them have aided in disseminating this impression.

As a result of this, so much sectional difference has been aroused, and the organization of the annual specialty congresses all over the United States has been so assiduously developed, that it very naturally appears to Mr. Hart that some difficulty may be found in restoring unity of professional sentiment and action. He has also been impressed with the facts that nowhere else than in America could the results of a common understanding on the relations of the profession to the public and of their duties to each other be more valuable, and that nowhere else does there exist a stronger need or a more useful sphere for medical thought and knowledge in guiding municipalities and executive officers in questions of public health and the government of public institutions, the endowment of science, and the maintenance of adequate standards of education and examination. "The future of the higher life in America," he says, "and the development of culture and mental progress, the struggle against commercialism and the blinding and corrupting worship of the dollar, lies largely with the professional classes. The medical tradition is essentially a protest and an antidote against this curse of new communities."

This kindly criticism is made by one that has, we believe, the interests of the medical profession of the world at heart, and it can not but do us good to see ourselves as others see us. It remains for our representative men to attempt to secure uniformity of action by our societies, so as to remove the existing opprobrium of the profession of the United States being a house divided against itself.

INTRAPERITONEAL HÆMORRHAGE.

The annual oration for 1893 before the Medical and Chirurgical Faculty of Maryland was delivered by Dr. Reginald H. Fitz, of Harvard University. The paper is an absorbingly interesting one and lacks little if anything of meriting the title of a classical essay. We find it reported in full in the *Maryland Medical Journal* for June 17th. The practical points of diagnosis and treatment occupy the chief places in the paper. Dr. Fitz would make a division of intraperitoneal hæmorrhages according to the gravity of the loss of blood as well as according to the situation of the escaped blood in the peritoneal cavity. The location of the hæmorrhage will often have much to do with the subsequent presence or absence of septic infection. Intraperitoneal hæmatocoele—a shut-in hæmorrhage—is generally pelvic in origin and site, occurs in women, and forms a tumor. If the bleeding does not continue and the conditions for recovery are favorable, there will frequently be an uneventful absorption of the clot. But the pelvis, being a region favorable to a septic infection of contained clots, may become the arena of a destructive inflammation of the surroundings. This may result in a discharge by the rectum, by the vagina, or by other channels, or rarely we meet with a quiet absorption without septic complications; and the possibility of these occurrences "is an insufficient justification for a severe operation for their prevention." These hæmorrhages, therefore, should be intelligently separated one from another, whether

they are immediately dangerous or only remotely so, and whether or not they are comparatively harmless.

The immediate danger from these extravasations is in rapidly progressing anæmia. The difficulty attending the diagnosis of these cases is illustrated by the following sentence of Dr. Fitz: "An exploratory laparotomy has often proved to be the only means by which the diagnosis has been established, and has repeatedly made clear that there has been no intraperitoneal hæmorrhage, which had been suspected." Only by that full knowledge of the complications arising from abdominal aneurysm, cancer, ectopic gestation, and many other conditions can the "diagnosis by exclusion" be made out. Veit has shown that there are no physical signs sufficient to prove the presence of a large quantity of blood free in the peritoneal cavity.

Dr. Fitz has a good opinion of laparotomy in carefully selected cases, but he is not an advocate for an early exploratory operation. If this operation is done, the case is ushered at once from the medical into the surgical domain. "If this is employed," he says, "the treatment becomes of necessity abdominal and surgical, whereas in many instances it should be medical or, if surgical, then vaginal or rectal." He favors medical treatment whenever it is feasible, for it either permits the patient to get well without the use of the knife or it renders possible an easy operation when needed, and one not demanding the maximum of skill. In this view of the case, we naturally expect to find Dr. Fitz an earnest friend of the operation of vaginal puncture, and from his remarks at the close of the oration we are led to infer that he has had a large and successful experience in that direction. He quotes Zweifel's statistics as to the forms of treatment other than by laparotomy as follows: By expectant treatment, 144 cases, of which 16.6 per cent. were fatal; by puncture, 66 cases, with 15 per cent. fatal; by vaginal incision, 30 cases, only 10 per cent. fatal.

The avoidance of laparotomy in these cases, except when there are well-defined and cogent reasons, may be set down as the teaching of this admirable and most readable discourse.

MINOR PARAGRAPHS.

WHATNOTS AS NECESSARY FURNITURE FOR A QUARANTINE STATION.

The Melbourne correspondent of the *British Medical Journal* states that the visitor to the quarantine station at Point Nepean is struck by the quantity of whatnots, in all kinds of designs and in various kinds of woods, indiscriminately scattered over the buildings. It appears that some years ago there was an unexpected demand for accommodation, owing to several large passenger steamers being sent into quarantine at the same time. The number of bedroom utensils was found inadequate to supply the wants of the inmates, and it was deemed necessary to telegraph for an additional supply to Melbourne. The telegraph operator being a lady, the delicate medical officer directed that a telegram be sent: "Forward at once to quarantine station one hundred whatnots." In those days anything ordered for the station was sent, no matter at what cost, and a contractor supplied the whatnots at short notice, at \$30 each.

THE CROTON WATER.

NEW YORK's water supply is not of such poor quality as some good people imagine; still, the measures that the board of health is reported to be about to take for its purification are such as would hardly be taken if the board did not feel that the water was in need of improvement. We have not much faith in those measures, but they will doubtless do no harm beyond using up money to very little purpose. The residents of that part of Westchester County in which the Croton water-shed is situated have observed that, whenever a new dam is completed and a fresh portion of territory is flooded, too little attention is paid to preparing the ground to serve as a place of storage for uncontaminated water, but barn-yards, privy-vaults, and other unsavory belongings of the deserted dwellings are allowed to remain to take their share in forming the bottom. It is to be hoped that in the further prosecution of the reservoir work more care will be taken as to such matters.

THE CHOLERA IN NAPLES.

Dr. Young, of the United States Marine-Hospital Service, having informed Surgeon-General Wyman of the presence of cholera in Naples and of the impossibility of enforcing the American immigration regulations at that port, has been ordered to refuse to give bills of health without their enforcement. This action is expected to have the effect of compelling the transportation companies either to conform to our rules or to stop bringing us immigrants by way of Naples.

DEATH FROM FOOT-BALL.

A MAN, aged twenty-seven years, a member of one of the Brooklyn teams that play foot-ball on Sunday, met with a fatal injury in a game played about a week ago. He received a kick in the abdomen, and his death ensued in about forty-eight hours. The game played by these teams is said to be different from that played by college undergraduates.

A RECENT CORONER'S JURY'S VERDICT.

At Highland, New York, the body of a drowned woman was taken out of the river recently. A jury, regularly constituted for the holding of an inquest, is reported to have rendered the following verdict. "We do say upon oath that the deceased came to her death by being found in the Hudson River, cause of death unknown."

THE "HEALING SPRING" OF HARLEM.

THE medicinal virtues attributed to a certain spring in Morningside Park seem to be imaginary. Worse than that, the water has been shown to come from an old well and to be badly polluted with sewage. Consequently the well has been ordered by the board of health to be filled up, and the water of all the wells remaining on Manhattan Island is to be subjected to the board's scrutiny.

THE ENGLISH DOCTOR'S VACATION.

MR. ERNEST HART very amiably and sincerely states in one of his recent papers on matters connected with his recent visit to America, that it is idle and foolish for any British doctor who has the leisure and the necessary means to think of spending his autumn elsewhere than in America.

ITEMS, ETC.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending July 25, 1893:

DISEASES.	Week ending July 18.		Week ending July 25.	
	Cases.	Deaths.	Cases.	Deaths.
Typhus.....	2	4	0	1
Typhoid fever.....	18	3	13	3
Scarlet fever.....	64	5	52	5
Cerebro-spinal meningitis.....	5	3	14	12
Measles.....	189	5	177	9
Diphtheria.....	111	34	99	37
Small-pox.....	3	0	11	1

A Novel Competition for Nurses.—The editor of the *Hospital*, a London weekly journal, asks us to print the following:

In the course of the discussion on Nurses' Homes, which took place at the International Congress at Chicago, Dr. Billings, the president, expressed the view that it was about time that women manifested the latent power claimed for them in a practical and definite form. He pointed out, for example, that it had been left to man—an impotent, weak creature as women knew him to be—to design and erect homes for nurses and training-school buildings. Architects and male experts had exhausted their ingenuity in designing such buildings, and he thought that congress was a very appropriate platform from which to invite the exhibition of woman's latent power by urging the superintendents to elaborate plans and enumerate each item which a model nurses' home and training school should contain. We have had much pleasure in falling in with Dr. Billings's suggestion, and have decided to organize a competition which will be open to any woman engaged in nursing from any part of the civilized world. The following details of the proposed competition will no doubt be of interest:

Attached to a Hospital or under Separate Management.—Two prizes—namely, a first prize of \$75 (£15) for the best plan sent in for competition, and a second prize of \$25 (£5)—are offered by the editor of the *Hospital*, London, England, for competition among lady superintendents, matrons, and nurses in the British Empire, the United States, and the countries of Europe.

Competitors must send in the proposals in type-written form, which must consist of two parts: (1) A statement setting forth categorically all the rooms and accommodation which are necessary in order to make the proposed nurses' home a model of what such an establishment should be where room is provided for from fifty to one hundred nurses; (2) a second statement and plan prepared in similar form which provides accommodation for from one hundred and fifty to two hundred nurses. Each of these specifications—(1) and (2)—must be accompanied by plans drawn in a uniform scale, and must explain how the proposed home for nurses can be extended, should the growth of the establishment render such a step necessary.

Conditions.—1. The competitors must send their names and addresses by November 1, 1893, to Dr. J. S. Billings, U. S. Army, Washington, D. C., and all plans and proposals presented for competition must reach Dr. Billings not later than January 1, 1894.

2. Dr. Billings, Dr. Henry M. Hurd, superintendent of the Johns Hopkins Hospital, Baltimore, Md., and Miss Sophia S. Palmer, superintendent of the Garfield Hospital, Washington, D. C., are appointed as the judges of the papers and plans submitted in this competition, and their decision will be final. Should the papers and plans submitted demand such a course, the judges reserve the right of withholding any award.

3. All proposals must be type-written on one side of the paper only, and all plans must be drawn to a uniform scale of one eighth inch to one foot.

SPECIAL NOTE.—It is proposed to publish an account of the competition, with a selection from the competing plans, such publication to be undertaken by the Scientific Press (Limited), 428 Strand, London, W. C., at their option, to whom papers and plans will be sent by the judges after they have made their award.

The Conditions of Admission to Practice in Iowa.—The following resolutions have been passed by the Iowa State Board of Medical Examiners:

First.—That from and after this date, June 27, 1893, this board will not issue certificates to practice medicine and surgery, in Iowa, except upon satisfactory examination, to the graduates of any medical college not requiring as a condition of graduation four years of medical study, including not less than three graded courses of medical lectures, of not less than six months each—no two of which said courses shall be within the same calendar year.

Second.—That while this board appreciates and commends the efforts made by the various national associations of medical colleges to raise the standard of medical education and have each adopted a curriculum of study greatly in advance of former years, this board under our present law, and the decision of the Supreme Court thereon, can not and will not recognize as "of good standing" any medical college belonging to such national association except upon compliance by announcement and practice, in letter and in spirit, with our schedule of minimum requirements.

Third.—That this board will not recognize, nor be bound by, any contracts between medical colleges and their students, either expressed or implied by their matriculation.

Fourth.—That any medical college failing at any session to conform to our requirements shall, upon satisfactory evidence thereof, be regarded as not in good standing for the session thus defective, and the secretary is hereby directed not to issue certificates to the graduates thereof except upon the authority of this board.

Fifth.—That this board recognizes and will exercise the right under the law to refuse certificates to the graduates of any medical college, without reference to its standing, upon palpable evidence of incompetency, or upon conviction of a felony in connection with the practice of medicine; or to revoke certificates for like causes. Further,

Whereas, A number of medical colleges in the United States and Canada have adopted and require a four years' graded course of medical lectures as a condition of graduation, and others have expressed a determination to do so, therefore,

Resolved, Sixth.—That after July 4, 1893, no medical college shall be recognized by this board as "of good standing" within the meaning of Section 1, Chapter 104, Laws 1886, that does not require as a condition of graduation four graded courses of medical lectures of not less than six months each—no two of which said courses shall be within the same calendar year.

Seventh.—That graduation from any college of dentistry and veterinary medicine or of pharmacy upon a satisfactory examination in anatomy, recognized by this board as of good standing, may be accepted as the equivalent of the first year's course of medical lectures by colleges requiring as a condition of graduation the graded courses above specified.

Eighth.—That the secretary of this board be and he is hereby directed to furnish all the medical colleges of the United States and Canada, and the secretaries of the respective national associations of medical colleges, together with the leading medical journals of the country, with a copy of the foregoing resolutions, and of our schedule of minimum requirements, and publish the same in the *Monthly Bulletin* of the State Board of Health.

The Pan-American Medical Congress.—The following named committees are announced: *Committee of Arrangements.*—Dr. Samuel S. Adams (chairman), Dr. J. R. Wellington (secretary), Dr. G. L. Magruder (treasurer). *Executive Committee.*—Dr. Samuel S. Adams (chairman), Surgeon-General George M. Sternberg of the army, Surgeon-General J. Rufus Tryon of the navy, Surgeon-General Walter Wyman of the Marine-Hospital Service, Dr. S. C. Busey, Dr. G. Wythe Cook, Dr. Carl H. A. Kleinschmidt, Dr. H. L. E. Johnson, Dr. Llewellyn Eliot, Dr. H. H. Barker, Dr. C. W. Richardson, Dr. W. Sinclair Bowen, Dr. George S. Ober, Dr. G. L. Magruder, Dr. J. R. Wellington, and John R. Walton, D. D. S. *Committee on Reception.*—Dr. S. C. Busey (chairman), Surgeon-General George M. Sternberg, Surgeon-General J. Rufus Tryon, Surgeon-General Walter Wyman, Dr. J. Ford Thompson, Dr. Charles Hagner, Dr. Louis Mackall, Dr. J. Taber Johnson, Dr. T. Morris Murray, Dr. G. Byrd Harrison, and Dr. Joseph H. Bryan. *Commit-*

tee on Entertainments.—Dr. G. Wythe Cook (chairman), Dr. G. N. Acker, and Dr. Thomas E. McArdle. *Committee on Registration.*—Dr. Carl H. A. Kleinschmidt (chairman), Dr. John S. McLain, and Dr. Johnson Elliot. *Committee on Railroads.*—Dr. H. L. E. Johnson (chairman), Dr. E. L. Tompkins, and Dr. J. Foster Scott. *Committee on Printing.*—Dr. Llewellyn Elliot (chairman), Dr. Thomas N. Vincent, and Dr. F. B. Bishop. *Committee on Halls and Exhibits.*—Dr. H. H. Barker (chairman), Dr. J. T. Winter, and Dr. C. M. Buchanan. *Committee on Ways and Means.*—Dr. C. W. Richardson (chairman), Dr. John Van Rensselaer, Dr. William Dillenback, Dr. Henry B. Deale, and Dr. William Compton. *Committee on Information.*—Dr. W. Sinclair Bowen (chairman), Dr. E. Oliver Belt, and Dr. F. S. Nash. *Committee on Hotels.*—Dr. George S. Ober (chairman), Dr. William E. Handy, and Dr. D. O. Leech. Mr. Ernest Hart, the editor of the *British Medical Journal*, and Professor Czerny, of Heidelberg, will be among the distinguished guests. Practically all of the governments have appointed official delegates to the congress in response to the invitation by the President of the United States. The United States Government will be represented by six delegates. The larger cities of all the Latin-American countries have appointed delegates to participate in the proceedings of the Sections in Hygiene, Climatology, and Demography, and on Marine Hygiene and Quarantine, and similar appointments are expected to be made by the cities of the United States. Seventy-six similar delegates have so far been appointed by the governors of States in the United States. A large number of delegates have been chosen by the medical colleges of the United States and other American countries to attend the Section in Medical Pedagogics, under the presidency of Professor J. Collins Warren, of Boston. A Section in *Materia Medica and Pharmacology* has been organized under the executive presidency of Professor Joseph P. Remington, of Longport, N. J., with Professor F. G. Ryan, 3739 Brown Street, Philadelphia, as English-speaking secretary. This section promises to be one of the most important of the entire congress. Delegates have been invited from all the pharmaceutical societies and colleges in all the Americas. Those contemplating attendance are invited to prepare papers on pharmaceutical topics. Titles should be sent at once to the secretary.

Letters to the Editor.

BUTCHERS' REFUSE.

NEW YORK, July 24, 1893.

To the Editor of the *New York Medical Journal*:

SIR: There is a nuisance in New York that no one seems to mind, no one to guard. I mean the butchers' refuse-collecting wagons. Any one who is obliged to traverse the crowded streets of our tenement districts between the eighth and eleventh morning hours will sometimes once in every half an hour, but sometimes every five or ten minutes, be shocked by a most heavy, foul, sickening smell, which he perceives as emanating from the by-going or standing, filled or filling-up, but always imperfectly-closed, collecting wagons. The refuse is piled up at the butcher's for several days and, it being unguarded against, enters into a rapid decomposition and then is collected. The collection itself is odious: the refuse being taken out in open baskets is, these being deposited there on the street, assorted and measured, at which procedure nearly every piece of foul fat or bone is rehandled, the repugnant smell in the mean time saturating the air all around. Between the procedures the wagons are usually opened also, and then both the sources their exhalations combine. I have been repeatedly stricken, without noticing such a wagon at all at first, with its smell at distances varying from thirty to fifty feet, and at the third and fourth story of a house, wherein it entered through the open

windows. The wagons themselves are all more or less defective and allow free escape of the gases; when they are full—and this is often to excess—the refuse is in some cases imperfectly covered, in some left uncovered, and they are then slowly driven through the streets, leaving whole floods of their baneful smell behind. Is this smell so harmless that no notice needs to be taken of it at all by the authorities? Is this some other kind of decomposition than that of dead animals on the street or of other animal decaying matter there, which all is so carefully and rapidly removed? Decidedly not! Animal decomposition in the free access of air with moisture and heat is always similar, and the danger of the decaying animal matter of the street and that of the butcher is practically the same and simply proportionate.

But how well-nigh ridiculous, then, seems the contrast between the nearly air-tight, whole dead-animal wagons and the neglected mostly semi-open wagons of their dead parts! As a small illustration of the harmfulness of the gases in question, let this be served: I was present at Mrs. B.'s, 423 East Seventy-second Street, a patient convalescing from cholera morbus. The lady was sitting on the bed all free from vomiting and diarrhoea for nearly twenty-four hours, when at once a foul smell, which proved to be that of a wagon collecting the refuse of a butcher in the neighboring house, filled the room (the patient occupies the second story of the house). Immediately upon inhaling this odor the patient complained of it and was taken with nausea and vomiting, followed by general prostration. There was absolutely no other imaginable cause for this than the overwhelming influence over the weakened nervous system of the foul gases—a nervous poisoning. And it is not simply the gases; there are certainly disseminated beside them the germs of the animal decomposition, which for the greater part are pathogenic germs, along our streets, where hundreds of weak children and invalids inhale them.

There is a help to this condition. Let the board of health give the subject proper attention, and if the press will assist, we shall soon see the refuse collected fresh, in early mornings, rapidly, and in clean and air-tight wagons. How far more grateful a field here than that of the critic of street excavation and Croton water!

ALOIS F. HEDLICKA, M. D.

A TAPEWORM REMOVED FROM A CHILD EIGHTEEN MONTHS OLD.

ANN ARBOR, MICH., July 19, 1893.

To the Editor of the *New York Medical Journal*:

SIR: The writer desires to record the following clinical note of a case that recently came under observation:

The first segment of the worm passed from the child on June 30th last. My diagnosis was made and treatment begun on the following day.

The treatment resorted to in this case consisted in first placing the child upon a restricted diet for two days, then the administration of four drops of oil of male fern in half a teaspoonful of glycerin night and morning, and also every second day five grains of compound jalap powder as a cathartic. On the tenth day of treatment the worm passed from the child entire. While the above-mentioned mode of treatment may be no better than the numerous others with which physicians are familiar, yet I desire to make record of it because it has been uniformly successful with me in several cases of *taenias* in adults.

While *taenia* may develop in the human being at all ages, from infants five days old* to the most aged, yet it is quite rare

* Professor S. G. Armor in Flint's *Practice of Medicine*, 4th edition, p. 618.

to find it in young children, since a child's mode of living is not, as a rule, such as will lead to the development of tapeworm.

J. A. WESSINGER, M. D.

Book Notices.

A Text-book of Medicine, for Students and Practitioners. By DR. ADOLPH STRÜMPPELL, Professor and Director of the Medical Clinique at Erlangen. Second American Edition. Translated, by permission, from the Second and Third, and thoroughly revised from the Sixth German Edition. By HERMAN F. VICKEY, A. B., M. D., Instructor in Clinical Medicine, Harvard University; Physician to Out-patients, Massachusetts General Hospital, etc.; and PHILIP COOMBS KNAPP, A. M., M. D., Clinical Instructor in Diseases of the Nervous System, Harvard University; Physician to Out-patients with Diseases of the Nervous System, Boston City Hospital, etc. With Editorial Notes by FREDERICK O. SHATTUCK, A. M., M. D., Jackson Professor of Clinical Medicine, Harvard University; Visiting Physician to the Massachusetts General Hospital, etc. With One Hundred and Nineteen Illustrations. New York: D. Appleton & Co., 1893. Pp. xxiii-1043.

This new edition of a text-book that the translators state in their preface is used in twenty-eight medical colleges in the United States contains the revisions of the sixth German edition, and so numerous are these additions that the present volume is virtually a new work. The text has been increased by fifty-eight pages, and eight new illustrations have been added.

In the chapter on typhoid fever suitable reference has been made to the experimental inoculation of animals with the typhoid bacilli, and to the difficulty of explaining how and under what peculiar circumstances these bacilli penetrate into the human body. The author suggests that the cases of "pneumotyphoid" are caused by primary pulmonary infection with the typhoid bacilli, thus taking a position against the theory of contemporaneous pneumococcus infection. He states that the nervous phenomena are due to the toxins elaborated in the system by the bacillus. Reference is made to the metatypoidal hemiplegia or aphasia that may be due to hæmorrhage, embolism, or a localized encephalitis. Acetanilide, kairin, thalline, and phenacetine are now referred to in the treatment.

In the chapter on scarlet fever the influence of the "chain-forming" micrococcus of Löffler in causing, at least, the complications of the disease is mentioned, also the necessity of suitably disinfecting the nose.

The chapter on small-pox has been enlarged by a section on the character of the variolous poison. While there is reference to the failure of the French experiments of 1865 to inoculate cows with the contents of variolous pustules and thus produce vaccinia, there is none to later investigators' successful attenuation of variolous matter in the cow.

The translators have made a useful addition, in the chapter on diphtheria, by giving Lovett and Munro's tracheotomy statistics and Dillon Brown's intubation statistics.

A chapter on influenza has been added. The author believes that the disease is caused by a specific germ. A section on amœbic dysentery has been added by the translators to the chapter on dysentery.

In the chapter on cholera the important rôle played by toxins in causing the symptoms of the disease is adverted to.

The chapter on malarial diseases does a great injustice in giving Marchiafava, Celli, and Golgi credit for discovering the *Hæmatozoon malaria*; we are glad to say that later in the chapter the translators properly credit Laveran with this discovery. It might be imagined that Strümpell was uncertain regarding the ætiology of these diseases, because he retains his old reference to Klebs' and Tommasi-Crudeli's supposed *Bacillus malaria*, to which no one nowadays attaches the slightest importance.

The translators might have enhanced the value of their brief chapter on typho-malarial fever by reference to the discoveries of Kinyoun and others of the *Hæmatozoon malaria* and the typhoid bacillus in patients affected with this disease. So, also, have they failed to make any reference in the chapter on yellow fever to Sternberg's important researches regarding this disease.

The chapter on septic and pyæmic diseases takes advantage of the latest discoveries in calling attention to the fact that, while it is not probable that all the septicopyæmic diseases are identical, still septicæmia, in the narrower acceptation of the word, corresponds more to an intoxication of the body, whether due to the toxins of organic metabolism [putrefaction of the author] or to those generated by the pyogenic bacteria.

A description of Pasteur's method of treatment has been added to the chapter on hydrophobia. And in the chapter on malignant pustule the method of attenuation of the anthrax bacilli is referred to.

The chapter on tuberculosis of the larynx now refers to the local treatment with lactic acid and with balsam of Peru, but it does not seem to us that it is to surgery rather than to endolaryngeal manipulations that we must look for the best treatment of this condition. Surgery has not a brilliant record in the treatment of the local manifestations of tuberculosis; in fact to-day it is yet pursuing experimental investigation of the subject, and laryngotomy would serve to remove but a part of the diseased tissue. It seems as if this chapter might be omitted, like that on syphilis of the larynx, that was in the first edition.

Strümpell is not prepared to say that there is absolute proof that the *Diplococcus pneumonia* is the genuine cause of pneumonia. In the treatment of the disease, he states, antipyretics are seldom useful, though antipyrine is to be preferred if any antipyretic must be used. We do not believe it is preferable to acetanilide; we are surprised to note the omission of any reference to the administration of apomorphine; and the doses of strychnine mentioned can usefully be employed much oftener, and in ordinary pneumonia as well as in that of alcoholic persons.

In the chapter on tuberculosis directions for staining the bacillus have been incorporated.

The criticism of the translators on the uselessness of an exploratory and an operative puncture in the treatment of pleurisy with effusion is merited.

The former brief section on actinomycosis has been expanded into a chapter in the present edition.

Attention is directed to the fact that any micro-organism may cause acute endocarditis. Brief references have been added in the section on congenital heart diseases to patency of the foramen ovale, to defects in the interventricular septum, to persistence of the ductus Botalli, and to congenital mitral and aortic stenosis. The employment of baths in the treatment of valvular heart disease is commended, and there is a description of the mechanical treatment of circulatory derangements advanced by Oertel.

The subject of the examination of the contents of the stomach by means of the stomach-tube has been rearranged, and

sections on hyperacidity and supersecretion of the gastric juice and on melæna neonatorum have been added. The chapter on gastric hæmorrhage has been omitted from this edition.

It seems to us that the editor is justified in his criticism of Strümpell's insistence on the necessity of a wet nurse, especially in consideration of the advances in the preparation of artificial food for infants.

In the chapter on typhlitis and perityphlitis the editor calls attention to the inconstant relation of the appendix to the cæcum. He commends a plan of treatment for this disease recommended by Dr. Sabine; food is abstained from until the temperature is normal, water is given freely, and stimulants are sparsely allowed, morphine is given in doses of about an eighth of a grain when there is pain or restlessness, no attempt to move the bowels is made, and a hot poultice is applied over the abdomen. This plan limits peristalsis, delays tissue metamorphosis, and secures bodily and mental rest.

In the chapter on stricture and obstruction of the intestines the translators urge early recourse to laparotomy.

A section has been added describing acute febrile jaundice.

Strümpell suggests that the term "articular neurosis" is more suitable than "articular neuralgia" for cases in which there is neuralgia of the joints.

The editor calls attention, in the chapter on habitual headache, to the necessity of determining in every case of persistent headache whether there is astigmatism or hypermetropia.

In the chapter on disturbances of motility reference is made to the use of the absolute galvanometer and to the faradaic reaction of degeneration. Very brief references to tic convulsif, to acromegaly, to ataxic paraplegia, to myriachit, to paramyoclonus multiplex, and to electrical chorea have been added; and Herter's table showing the functions of the segments of the spinal cord at the level of the various nerve roots has been introduced.

In a brief note on Morvan's disease the editor states that it is merely myelosingosis associated with neuritis; indubitable cases of the latter disease have been reported as Morvan's disease, and Zambaco Pasha has called attention to the fact that the patients whom Morvan originally reported as suffering with analgesic panaritium were actually affected with anæsthetic leprosy; so the theory of this identity is untenable.

A summary of the focal symptoms of tumors in different parts of the brain has been inserted. We are surprised to note the editor's apparent sanction of the excision of epileptogenous cortical foci.

The chapter on tetanus is made to conform to our present knowledge by the addition of a reference to the *Bacillus tetani*.

A chapter on the traumatic neuroses and one on acute poliomyelitis have been added.

Many of the chapters in the volume have been rearranged and minor facts inserted. The translators have made the occasion of the appearance of a new edition an opportunity to modify a number of expressions, thus perfecting the literary style of the work. The new edition merits an increase of the popularity that has been accorded its predecessor.

A Treatise, Practical and Theoretical, on Cancers and the Cancer Process. By HERBERT SNOW, M. D. (London), etc., Surgeon to the Cancer Hospital. London: J. and A. Churchill, 1893. Pp. xlii-371.

THE writer's position in the Cancer Hospital of London has given him exceptional opportunities for the study of this dreadful and dreaded disease, and his book is an outcome of his experience there. We think he would have done better to entitle

his book *A Study of Malignant Diseases*. It is not creditable to physicians as educated men that they cling so persistently to these ancient terms which are so often used arbitrarily to express the fancy of those who originated them. The author's definitions are clear and terse. There can be no misunderstanding such a statement as this: "Practically every cancer is but a mass of actively growing cells." With regard to the etiology of the disease, a subject which is just now evoking the most earnest discussion and investigation, he is disappointing. He objects to the microbic theory of its origin, and thinks there is no evidence to favor the parasitic nature of the bodies described by Armand Ruffer as "parasitic protozoa." The enormously important work in this field which has been done by Metschnikoff, Adamkiewicz, Sawtschenko, and others, chiefly Russians, is not mentioned. He lays great stress upon the influence of the nervous system in causing malignant disease, pointing to the preponderance of cases in the breast and uterus to establish his statement. But unfortunately a very great number of these cases do not occur in women who are excessively emotional or at a time of life when the emotions are most active. Besides, a history of irritation and irritants is so common in all forms of the disease, and in either sex, that his argument is not well sustained. His classification of the disease into nine forms with genera and species is complicated and neither so scientific nor rational, we think, as a classification upon an anatomical and histological basis. We are glad to see that he has called attention to the fact that a considerable number of the so-called benign neoplasms take on malignant changes, and it is well to impress decidedly upon the profession the fact that the line of distinction between benign and malignant growths is extremely difficult to fix; hence the necessity of early and careful attention in all forms of new growth. In his remarks concerning treatment he expresses approval of the extensive use of the cautery, both actual and chemical. In this we think he is correct, and it is probable that the exclusive use of the knife is responsible for not a few failures which might have been obviated by the use of other means. His chapter on cancer of the uterus is not very satisfactory. So much has been done in this field, such extensive additions to our knowledge have been made, especially by German operators, if not always with such results as could be desired, that it would seem as if a more exhaustive treatment of the subject might have been expected. A considerable number of very excellent plates illustrates the histological peculiarities of the various forms of the diseases described.

Cholera: its Causes, Symptoms, Pathology, and Treatment. By ROBERTS BARTHOLOW, M. D., LL. D., Emeritus Professor of Materia Medica, General Therapeutics, and Hygiene in the Jefferson Medical College of Philadelphia, etc. Philadelphia: Lea Brothers & Co., 1893. Pp. vii-13 to 132.

THE author has sought to make a practical book in the smallest compass, avoiding historical accounts of successive outbreaks and disquisitions on disputed etiological points. In his first chapter, on the history of cholera, he properly characterizes cholérine as an unscientific term when used, as it sometimes is, to denote a mild form of cholera that may develop severer symptoms; as there is no case of cholera without the spirillum, the presence of this organism makes the case of supposed cholérine one of cholera. The name cholérine might be properly applied to those sporadic cases of choleroïd disease, sometimes also appearing in circumscribed epidemics, that have been observed in various parts of this country and have caused Dr. Bartholow to believe that the comma bacillus has become naturalized here and maintains itself, if but feebly. As he truly states, only a proper bacteriological investigation can set-

tle this question, and such an investigation was made last December in a supposed outbreak of cholera at Little Rock, when the absence of the cholera spirillum was conclusively demonstrated.

There is a slight error on page 17 in the statement that when the third case of cholera appeared in Havre, on August 3, 1892, the disease was already existent in epidemic form in Hamburg. The first case of cholera in the latter city appeared on the night of August 14-15th, and the disease became epidemic immediately thereafter. It seems to us that the statement on page 20 that "when Hamburg was attacked with cholera no communication could be traced with any infected locality" is likely to give the reader the impression that the Hamburg epidemic originated *de novo*. Such a position is untenable, for Reincke, the chief of the Hamburg health department, stated that there had been a number of Russian immigrants in Hamburg who had come from suspected localities; and that city had been, previous to the appearance of the epidemic, in communication by sea with Russia as well as with France, in each of which countries cholera existed.

The author considers at sufficient length the two facts of supreme importance in the ætiology of cholera: the influence of bad hygiene—State, municipal, and personal—and the influence of the cholera spirillum. The predisposition of food purveyors to become affected with cholera, to which the author refers, seems to be explicable by the facts that flies, as Sawtschenko has shown, may diffuse the microbe, and that the latter easily propagates in the insects' intestinal canal.

The symptoms and pathology of the disease are described separately in a brief and comprehensive manner.

The final chapter, on the treatment of cholera, gives the prophylactic measures, including quarantine and the latest therapeutical methods in vogue in India, Europe, and America.

The volume is written in the author's usual pleasant style, and will satisfy the desire of any one that wishes to obtain the most recent information on the subject.

Manual of Practical Medical and Physiological Chemistry.

By CHARLES E. PELLEW, E. M., Demonstrator of Physics and Chemistry in the College of Physicians and Surgeons, New York, etc. With Illustrations. New York: D. Appleton & Co., 1892. Pp. xiv to 314. [Price, \$2.50.]

This book is an extension and amplification by the author of thirty lessons prepared for the students of the Medical Department of Columbia College, first published in pamphlet form in 1889. It deals with all of the matters in physiological chemistry with which medical students should be familiar, and the general practitioner will find it the best book of its kind published in this country. The subject becomes every year of more and more importance, as the questions of digestion and assimilation, and the treatment of their disorders, become more complicated, and depend more upon our absolute knowledge of their chemical processes. Every one will be repaid by the careful study of this book, containing as it does chapters upon food-stuffs, the organic and inorganic constituents of the body, and upon the analysis of drinking waters and the urine. To many it will be rudimentary doubtless, intended as it is chiefly for beginners, but there are large numbers of practitioners who will find here much food for examination and thought. Some such book is indeed now indispensable.

An Introduction to Practical Bacteriology for Physicians, Chemists, and Students. By Dr. W. MIGULA, Lecturer on Botany in the Grand-ducal Technical High School of Karlsruhe. Translated by M. CAMPBELL, and edited by H. J.

CAMPBELL, M. D., M. R. C. P., etc. With Nine Illustrations in the Text and Two Plates. London: Swan, Sonnenschein, & Co.; New York: Macmillan & Co., 1893. Pp. vii-247. [Price, \$1.60.]

It is the author's purpose that this volume should serve as a short text-book for a course in bacteriology. The necessary outfit for bacteriological research is described, and instructions are given for examining living bacteria, for preparing nutrient media, for cultivating the micro-organisms on plates, in Es-march's tubes, by stroke or puncture, at high temperatures, and by anaerobic methods for staining the bacteria, spores, and flagella, and for mounting. Certain of the more important microphytes are described so that the student may recognize and study them. The volume is essentially a practical one that is not intended to supplant the larger and well-known textbooks on this subject, but to serve as a guide for students in biology and for physicians whose time does not permit of elaborate and extensive investigation of the subject.

Transactions of the American Association of Obstetricians and Gynecologists, vol. v, for the year 1892. Philadelphia: William J. Dornau. Pp. viii-529.

Transactions of the Southern Surgical and Gynecological Association, vol. v. Fifth Session, held at Louisville, Ky., November 16, 17, and 18, 1892. Published by the Association, 1893. Pp. xl-434.

THESE two volumes, covering practically the same ground, and the work in large measure of the same men, give a very fair idea of the industry and progress of American workers. The day is happily past when such workers can be referred to as either uneducated or unscientific. They are gathering the best that the world can give them and adding to it. These volumes also demonstrate that it is no longer to New York, or Philadelphia, or Boston that we are to turn exclusively for excellence and originality; development has been going on in all directions. This fact must have a most important bearing upon the welfare of the people of the entire country.

Miscellany.

Cholera in Calcutta.—At a meeting of the Calcutta Medical Society, held on May 10th, as reported in the June number of the *Indian Medical Gazette*, the president, Dr. Kailash Chunder Bose, read a paper entitled Some Points regarding the Prevalence of Cholera in Calcutta. He said:

"The early history of cholera is quite obscure, and the theory of its origin has been chiefly based upon the idle conjectures of the ancients, who in their feeble attempt to describe the pathology of the disease have linked it with their religion and dismissed the subject by simply attributing cholera to the vengeance of the gods and to the misfortune of the land where it makes its appearance. The Bishuchika and the Mohamoree of the Ayshed are in all probabilities the cholera of the English authors, but the description of the phases of the disease as given in that sacred work differs from the statements of the Western authors in more points than one. In one of the sacred books of the Chinese Whoongshwho describes a disease whose symptoms are in many respects similar to those of the Bishuchika of the ancient Hindus. The Mohammedan writers of the middle ages have also made mention of the disease and its outbreak in Egypt and Arabia, but the way in which they have treated the subject does not help us in the least in knowing the nature of the illness. Gaspar Correa, a Portuguese, was the first European who described an epidemic outbreak of cholera in Hindustan in the year 1503. Sydenham states that cholera morbus was

raging in London in 1676. From these records it shows that this direful disease was certainly known to the ancients, and that it has visited every country, not even the remotest islands and isolated populations excepted. I do not like to take up your time by going over the subject in detail, but will try to confine myself to facts which directly concern Calcutta. As no reliable history of the first visit of cholera to Calcutta can be had from authentic record, we need not attempt to trace it out. Dr. Macnamara, who has almost exhausted the subject, mentions that in 1781-82 cholera was very deadly in Calcutta, and the Government reported to the home authorities that it had pursued its course northward. Cholera, the most dreaded of diseases, has selected Calcutta for its home, and it is from here that its germs are sent to different parts of the world, where, under favorable circumstances, they grow and bear fruit. People who have no idea of Calcutta, the City of Palaces, will likely want to know the reason of its being the center of cholera, and for them it needs that I must give in a few words the geographical position of Calcutta and the habits of the people who reside in it. Calcutta lies on the left bank of the river Hooghly, and its height above the sea-level is only eighteen feet. Its site is decidedly flat, and its inclination is not toward the river, but toward the salt lake which lies on its east. Its soil is soft and moist. During drought the ground water stands from thirteen to fifteen feet below the surface level, while during rains it rises to the ground level. In Calcutta the summer is long and the winter short; May and June being the hottest, and December and January the coldest months of the year. The rainy season commences from the 15th of June, and lasts till the end of August. The average rainfall is 66 inches. The highest temperature is 100° F., and is generally in May, and the lowest temperature, in January, is 60° F. The climate of Calcutta is hot, moist, and therefore very favorable to the growth of all kinds of micro-organisms. The northern portion of the town is the most populous portion, and forms the native quarter. The southern portion is entirely occupied by the Europeans, and is therefore the cleanest and healthiest portion of the city. Of the people who reside within the city, only twenty-nine per cent. are born in Calcutta, and the rest have come from the various parts of the world. The construction of its buildings which adorn the city is very defective in the native quarter of the town, and rooms have been built quite regardless of the fundamental rules of hygiene. Nearly half of the northern portion of the town has been occupied by bustees or clusters of huts inhabited by the lower class of citizens. At the center of each big bustee you will find a tank or pond excavated by the landlord for the water-supply of his tenants. The tank is used for cleansing utensils of the bustee people; in it they wash their body and take their daily ablution, domestic animals are washed in the bustee tank, and the water of such tank forms their drink. The bustee men, from their idle habits, do not care to exert themselves for the supply of fresh water, which is only kept at a reasonable distance from their bustee. The arrangement of the huts in a bustee is altogether bad; the huts are raised in such a fashion as to preclude the intrusion of the sun and obstruct the perflation of air. A correct picture of a bustee can be had from the annual report of Dr. W. J. Simpson, the energetic Health Officer of Calcutta. It is usually from the existence of such bustees that the town is infected with diverse zymotic diseases, and the first case of cholera, when this direful disease makes its appearance in Calcutta, would invariably be from a bustee. Fifteen years ago, when I was attached to the Campbell Hospital, I invariably noted that the first case of cholera which was admitted into the hospital was either brought from a bustee in Manicktolla, or in Entally, and from the total number of cases admitted it was found out that nearly two thirds of the cases were in men who had recently come to Calcutta. Now it is time for us to consider from what sources cholera gets access into the town, and how far it is possible to ward it off. To achieve the first object would require much knowledge and careful study of the history of cases that come under treatment. In the year 1890 Dr. Simpson issued a form of certificate to be filled up by the medical attendant stating therein the cause, source, and duration of the disease under which death has taken place. I don't know what led the health officer to discontinue this practice. If these certificates were recorded they would have served a valuable document for the health officer in forming his idea of the cause and source of diverse epidemics, which now and then break out

in Calcutta and its suburbs. Of the sources through which cholera comes to Calcutta I would try to trace them under two heads: first, sources which are within the town—that is, *inborn*; and second, sources which spring up from extraneous causes. The first includes sanitary defects, of which I would beg leave to point out one or two here.

"Neglect of clearing out the streets has been followed by very bad results. In the African portion of the town, I mean to say Burra Bazar, the lanes and alleys are never cleared once in a week, and the deposit of refuse and *débris*, favored by the moist heat of the atmosphere, harbors diseases of diverse nature. Cholera and typhoid may spring up from this source alone.

"The underground system of drainage contrived to carry the sewer and waste water of the town is a process which, for many reasons, can never be carried into Calcutta without the fear of its being a source of ill-health and disease to the inhabitants of the town. I shall later on mention what relation it bears to the propagation of cholera. I admit that the city has undergone much improvement within the last twenty years, but still there remains much to be improved. It is not my duty to point out all the defects of our town, for they are well known to the health officer, who spares no pain or trouble to advise the corporation on these matters. But there are many things which, unless brought to the notice of the health officer, can never be attended to by him. For instance, the health officer may not know that, in the lanes of Burra Bazar, the *débris* is allowed to decompose and give off noxious gas which contaminates the atmosphere which the people of this district breathe. In case of death happening from typhoid, dysentery, cholera, small-pox, you will invariably find that the soiled rags, linen, and beddings are thrown recklessly on the street, and sometimes underneath, or in the immediate vicinity of the watering-pipes (hydrants), and there they remain until the domes who collect old rags for shipment to foreign countries remove them. Could any one of us form an accurate idea of the mischief which would arise from this source alone? In the houses of people who live in Burra Bazar, the old-fashioned well excavated in the immediate vicinity of privies or sewer traps still exists, and its water, though not used for culinary purposes, is used for ablution during the night when filtered water ceases to run through the pipes. In some of the houses reservoirs for storing filtered water have been kept in close proximity to the sewer trap. The cesspools and gullies are no less dangerous than the soiled linen of cholera patients. If any one of you present here doubts the existence of such nuisances in the heart of the town, and in the most paying portion of it, I would ask him to drive through the Shama Bae's Lane, Narain Pershad Babu's Lane, Armenian Street, Hunsucker Lane, and Cotton Street, and then he will be able to estimate the amount of evil wantonly allowed to exist through the negligence of the corporation. Carrying water by the bhisties, and supplying it to the people who live in lanes and alleys, where the pipe-water is not yet distributed, is a practice quite unsafe for the health and well-being of the people. Besides those just mentioned, there are many other sources of such evils which I have not time to mention, but which might also with propriety be included in this list. Of the sources which lie without the town and through which cholera often comes within it, none is more dangerous than the practice of getting milk through the *gallas* who live in the suburbs of Calcutta. I occasionally come across cases of cholera where bad milk had been the cause of the disease. If you all believe in the germ theory of cholera, you can not but believe that milk is the best medium through which the bacilli could get access into the system. There is a class of men who only take raw milk in a certain number of days in the month, and the chances of their falling victims to the disease are always very great. Dr. McLeod, while lecturing on milk before a large and influential body of gentlemen, has left nothing on the subject, and any further discussion on it would, I am afraid, be mere repetition of the arguments already urged by the learned professor. Does boiling prevent the growth of the micro-organism? The itinerant confectioners who come from the adjoining or distant villages to sell sweetmeat have sometimes brought cholera with their sweets. Calcutta being the center of commerce, where thousands of men daily come from various parts of the world, it becomes a difficult task to enumerate in one place the numberless factors of cholera, from which it may at any moment develop and spread over. Besides those just mentioned, there remain a few others

which require a passing notice. We all know that the use of filtered water during an epidemic of cholera is of more value than hundreds of therapeutical agents sprinkled over the town to prevent spread of this disease, and this filtered water has, in many instances, been denied to the people by the corporation of Calcutta. It was only the other day cholera broke out in a bustee in Mooktarām Babu's Street; this bustee was supplied with filtered water. The landlord could not pay his water-rate in due time. The water connection was cut off when cholera was existing within the bustee, and two or three patients were laid up with it. The medical inspector with his usual remarks applied to the authorities for the immediate reconnection of the water-pipe, but the authorities could not find a provision under which they could connect the pipes before the payment of arrears of rent. Another case similarly appalling, but at the same time quite amusing, lately occurred in the Jorasanko division of the town. Here the water connection of a cholera-stricken house was cut off for the debt of another individual who lived in the adjoining house. I need not now tire your patience with the description of the municipal arrangement of our town, but would at once revert to the question of cholera which forms the principal subject of our discussion.

"Cases of cholera have been reported to have occurred from the use of some special kind of food, such as stale or preserved meat, crabs, lobsters, and other shell-fish. Over-ripe and unripe fruits have been known to produce cholera. A respectable European family, consisting of six members, was reported to have taken over-ripe papais, and suffered from choleraic symptoms, and one of the members died in ten hours. I know an instance where a young Bengali Babu indulged too much in mangoes and fell a victim to cholera. The symptoms in this case were quite unmistakable. Indiscriminate use of lichens and berries has been in many instances the cause of diarrhoea and dysentery, and sometimes their use has been followed by cholera. Two young girls, sisters, were brought under my treatment for purging and vomiting said to have been the effect of indigestion brought on by the free use of watermelons. There were pieces of undigested watermelons in the vomited matter; the stools were slightly tinged yellow, but the patients were found to be sinking fast, and soon the stools became characteristic. In the absence of another case of cholera in the vicinity, I could only attribute the disease to the use of watermelons. These two cases, I am glad to be able to say, ultimately recovered.

"Green mangoes, plums, pineapples have often been known to produce gastro-intestinal irritation, and in isolated instances they have actually produced cholera. A young boy, aged eight, was placed under my treatment for cholera; he had cramps and spasms all over the body; his pulse, though not absent altogether, was still flickering and rapid; retching and vomiting were persistent; stools frequent and characteristic, but the urine never ceased to flow. The history revealed that he was taking the same kind of food with the other members of his house, but he took some green mangoes, which, as he said, upset him. His sister, a girl of five, who took some green mangoes with her brother, had acute dysentery, and had to be confined to her bed for ten or twelve days. The first stool she had after a full dose of ipecac contained, among other things, thin slices of mangoes.

"Dr. Payne, during his incumbency as the health officer of Calcutta, reasonably thought that if all the tanks of Calcutta were filled up with any kind of material, no matter whether it be town refuse or garbage, all possible chances of cholera could be removed. He carried his theory into practice. The result, however, proved abortive; for, during the process of filling up tanks, several valuable lives were lost from an outbreak of cholera in the neighborhood, so that where there was no cholera before, cholera was actually invited. From the subsequent results of this new procedure, we could safely infer that the learned doctor intended to remove one disease by the introduction of another of a still more formidable nature. Dr. Kenneth McLeod, who succeeded Dr. Payne, carried out tank-filling with great caution. He only urged for the obliteration of such tanks whose existence was calculated to be detrimental to the health of the neighbors. He was entirely against the use of garbage in filling up tanks. Dr. W. J. Simpson, the present incumbent, has clearly proved that by re-excavating filthy tanks he could greatly improve the condition of the bustee in which it existed. The Marcus Square in Machoa Bazar Street is an instance where

the condition of the bustee was surprisingly improved after the tank was re-excavated. Cholera and diarrhoea, which were yearly reported in this bustee, however, entirely ceased to exist.

"In Calcutta there is no special season for cholera. It may appear at any time during the year, but the most favorable season for its outbreak is summer. Before the introduction of the filtered water into the city the mortality from cholera during the months of March, April, May, and June was always very high. Elderly women used to read hymns and prayers in honor of the presiding deity, and great restriction of diet was observed. Potatoes, pumpkins, melons, rotten fish, etc., were scrupulously avoided. The advent of rains was looked upon with great eagerness, for it was the common belief of the people that cholera will disappear with the appearance of rains. During winter the city was perfectly free from the ravages of cholera. But a great change has taken place since then. October, November, December, March, April, and May are the favorable months for cholera. Whenever there is a sudden transition in the atmospheric temperature, cholera is almost sure to make its appearance. I have always noticed that cholera and the *Hori* festival of the Marwaris are linked together. You would invariably find cholera creep into the bustees of Burra Bazar during *Hori*, which lasts for at least seven days. This festival comes off on or about the 10th of March. It is generally during this festival people recklessly expose themselves to the influences of diseases. They take off their warm clothing and put pounds of red powder on their body which prevents the action of the skin. The red powder is known by the name of *galal*, and is prepared from the best kind of logwood. On account of the high price of the logwood, another powder, which is called *ahur*, has of late been introduced into the market to meet the demand of the poorer class of men. The *ahur* is prepared by the admixture of magenta and arrowroot in their various proportions. The powder is freely exchanged among people who observe the *Hori*. The usual place, where the amusement of dusting the red powder on the face and eyes of friends takes place, is on the terrace of the house and in the public road. It is more commonly on the terrace of the houses these people throng themselves quite regardless of the sun or rain. They drink *bhāng* to excess and only use sweets and pastry as their food. They keep up nights in debauchery and in the morning they take *bhāng* in full doses, and then as the sun rises they pour colored water on their body, which is sometimes besmeared with the dirt and filth of the streets. These irregularities are followed by serious illness. Cholera creeps in insidiously and attacks the debauchees by dozens. If a correct record be kept you would find that cholera among the people of Burra Bazar is introduced with the advent of *Hori*, a festival which ought to be removed by law.

"Whenever and wherever there has been congregation of men there have been deaths from cholera. In Orissa, where the gathering during the Rathjatra is always very great, the death-rate from cholera in that province has always been inconceivably great. Of the pilgrims who repair to the spot nearly one fourth of the number die there. Most of those who return to Calcutta are counted either as convalescents from cholera or still suffering from the sequel of the disease. It is after the return of such pilgrims that we get reports of cholera from different sections of the town. Formerly during the Kumbh *mela* at Hurdwar pilgrims used to die in hundreds, but since the authorities have enforced certain sanitary rules the mortality has been greatly minimized. There was no casualty during the last *mela*. The report given by Dr. Simpson regarding the outbreak of cholera in Calcutta during the Ardhodoya is replete with informations from which inference may be satisfactorily drawn on the point now under discussion. In Tarakespur and Byjnath, where pilgrims gather at the end of every Bengalee year, cholera invariably breaks out in an epidemic form during the *mela* and disappears after the festival is over.

"I do not know what the people in other sections of the town do with regard to the disposal of the cholera evacuations. In sections D E and G H people do not observe any special rule in removing the discharges from a cholera patient. The stools and vomited matter, as I have said before, are thrown on the public streets when they are collected in separate basins; but in case where such stools are passed on the bedclothes and on the floor, as is often the case, a thin layer of moist earth or ashes is sprinkled over them and allowed to stand over

for hours and then washed away with a small quantity of water. When cholera occurs in mercantile shops the shopkeepers minimize their labor by stretching gunny bags underneath the patient and keeping them in position until the patient is thoroughly cured or removed by death. The soiled bags when sufficiently dry are utilized in shipping cargoes to various parts of the town. Some dispose of them at a cheap rate to hawkers. As regards the soiled woolen stuffs and costly cotton fabrics, they are sent to the dhobies for washing, and the dhobies carry the seeds in different directions.

"Theoretically speaking, cholera is contagious and segregation of the sick is absolutely necessary to prevent its spread, but experience has taught us to negative this theory, and I know of instances where people who closely attended upon cholera patients were never affected with the disease. In the wards of the Campbell Hospital cholera patients were kept in one row with the other cases, and no patient was ever reported to have caught the contagion. Similarly in the Medical College Hospital the cholera and the accident wards were separated by screen partitions, and still there was no spread of the disease. The nurse of the cholera ward, who was always attentive and kind to the patients, was never known to have suffered from any slight indisposition for a single day; on the contrary, she enjoyed excellent health and was the strongest of her batch. It is a common practice among the natives of this country that they flock round the sick-bed, and still they do not carry the infection. I knew an instance where a fond mother closely nursed her three children down with cholera, and subsequently died of it, but still the mother escaped. What could be more favorable circumstances for the development of the micro-organisms than those under which the bereaved mother was placed? Her hands were actually soaked in cholera stools for hours, and still she had no symptoms of the disease. It is needless to multiply instances; enough it would be to say that cholera is not communicable from man to man, and is therefore not directly contagious. It can only develop when the micro-organisms get access into the alimentary canal of an individual pre-disposed to its influences. I do not believe that micro-organisms could enter into the lungs and develop symptoms.

"We can not put reliance on the mortuary returns of our city. The cholera and tetanus columns of the register have been reserved by the registrar of deaths to fill them up during emergency; when the cause of the disease is not forthcoming he would at once put it under the column of cholera. In cases when an infant body is brought before him he puts it under the head of tetanus. I had a melancholy occasion to go to the burning ghat, and during my short stay there I noted the irregularity and reported the matter to the health officer. Several deaths caused by the reckless use of strong purgatives have been recorded as deaths from cholera.

"It has of late been conclusively proved that cholera is due to the presence of a specific micro-organism in the system, and this micro-organism has been detected in the evacuations of cholera patients or in the intestines of those who have died under it. This specific germ has been designated by Koch as comma bacilli on account of its comma-like shape. Its nature and the mode of its cultivation have been given in the standard works on the disease. The germ theory of cholera has been universally accepted, but there are disputes regarding comma bacilli being the specific micro-organism of cholera. Klein and other workers have ignored this positive assertion of Professor Koch. Professor Cunningham has strong reason to disbelieve the arguments urged in support of comma bacilli. The germ theory is not original, and nobody could claim that he was the first man who worked in this direction. Whatever progress the germ theory has made in the literature of cholera, it is in reality an idea taken from the ancients. The pathologists of the eighteenth century had also worked on this tract, but with their comparatively less knowledge of the microscope they failed to discover the micro-organisms. Who do not know that there are myriads of micro-organisms floating with the motes on the air we breathe, and who do not know that we constantly swallow micro-organisms and digest them before they get sufficient time to develop ptomaines within our system? Professor Hünigberg, a German worker, came down to Calcutta more than a quarter of century ago to study cholera. He opened a big hospital in Jorabagan to receive patients in all stages of the disease. The treatment he adopted was the injection of quassa hypo-

dermically; evidently he did it with the object of killing the micro-organisms, for quassa is a poison to all lower organisms. The result of his treatment was anything but satisfactory, and the philanthropic gentleman ultimately left the country. The laurel reserved was for Professor Koch, who discovered the special micro-organism in the discharge of cholera patients.

"They [the micro-organisms of cholera] have been found to thrive well in an alkaline medium, with a definite amount of heat and moisture. When the stomach of a person fulfills all the conditions necessary for the development of comma bacilli, it is then the person into whose system they have got access suffers from all the symptoms of the disease. Professor Koch has, after repeated trials, concluded that the comma bacilli are the specific micro-organisms of cholera. These bacilli under favorable circumstances retain their vitality for a much longer period than what they are generally supposed to do. They only wither at a temperature above 50° C. or at one below 15° C. Professor Koch has found by experiments that these bacilli are completely destroyed by any strong acid. Its cultivation is better conducted in sterilized milk and in well-water. The bacilli themselves are not capable of producing the symptoms, but the ptomaine they produce within the system has been said to be the cause of the disease. The question here arises how this ptomaine is generated within the system by these bacilli? Have we got any means to ascertain the composition of this chemical product, if I can call it so? Do diverse kinds of bacilli produce diverse kinds of ptomaines? Do we know the length of time which the ptomaine requires to act as ptomaine? We must be satisfied on these points first before we can accept such theories.

"Before accepting the theory of the comma bacilli we must try to know whether such comma bacilli have ever been discovered outside the field of cholera. Dr. W. J. Simpson, in his most interesting lecture on Pilgrims and Cholera, has distinctly said that he discovered comma bacilli in the water of Hurdwar, where there was not a single case of cholera. Comma bacilli have been found in the saliva of man. How would the learned supporters of the comma-bacilli theory explain or account for the following fact, which I beg leave to mention here: A party of twenty-two men went out to Kalighat to worship the goddess. They started from No. 9 Hunsucker Lane at about twelve noon and reached Kalighat at 1.30 p.m. They all put up in a hut situated on the border of a filthy tank. They used the tank water for cooking their food and some of them may have drunk this water. They ate one kind of food at about six o'clock in the evening; they returned to Hunsucker at 8 p.m. Between nine and ten in the night—that is, an hour or two after their arrival—nine members of the party had cholera, and nine died the next day. The rest—thirteen—who escaped, were opium eaters. How would you account for this unusually rapid growth of the bacilli and the rapid production of the ptomaine within the system? These people, I must mention, were fond of acids, and they must have taken sufficient quantity of acid with their food. If we are to believe in the comma-bacilli theory, we must satisfy ourselves by saying that these nine stomachs were in one condition.

"Professor Koch has said that these bacilli are entirely destroyed by the action of an acid medium. But most of the cholera cases happen in men who take lots of acid with their food and suffer from acid dyspepsia. I am afraid, gentlemen, I am tiring your patience, and therefore stop by bringing another fact for your discussion. Granting that comma bacilli are the specific micro-organisms of cholera, what becomes of the bacilli after the stage of reaction? I know that the answer you would give would be to this effect: that all the bacilli were wasted away in generating ptomaine. My next question would be that in native houses the beddings and utensils and the blanket kept on the floor of the room are not changed or removed until the patient is pronounced thoroughly cured and fit to walk about. What became of the convalescent patient and what would be the action of the fresh bacilli which have been rapidly growing within the moist bedding and blankets and freely entering into his system? If one attack of cholera does not offer immunity against another, how is it that the patient escapes from the second attack?"

The Reduction of Prolapsed Hemorrhoids.—In a paper entitled Brief Clinical Memoranda, read in the Section of Practice of Medicine

at the recent meeting of the American Medical Association, published in the *Journal of the American Medical Association* for July 16th, Dr. Henry D. Didana, of Syracuse, N. Y., said:

"Much suffering is occasionally the result of protruding piles. The victim usually manages, by taking compound licorice powder at night or some saline in the morning, to obviate constipation. Or he uses an enema after breakfast to secure a movement. The hemorrhoids descend, but they are replaced with little difficulty. Sometimes, however, they are very much enlarged or sensitive, and long-continued efforts to put them back prove a failure. The sufferer regrets that he has not heeded the advice of his neighbors and submitted to an operation. Regrets, however, are unavailing to give present relief. He sends for the family physician. The doctor works faithfully, inflicting much pain, and happily accomplishes his object. But not invariably. Now and then his best efforts are fruitless, and anodyne ointments and hot cataplasms are called to his aid. Meantime the suffering continues with little amelioration. The soothing influence of the applications becomes manifest after a long time, and the wretched tumors are put back where they do the least harm.

"A repetition of this misery and delayed relief is not an infrequent occurrence. Still, the long-suffering victim dreads a surgical operation of any kind, and tries to hope that each attack will be the last.

"Now, it may be some satisfaction to the doctor, as well as great comfort to the patient, to know a comparatively easy method of effecting reduction. This is it: Posture may be important, but the best one is not always required. In moderately severe cases the patient may be on his back with knees drawn up. If the hemorrhoids are very tender from strangulation and manipulation, cocaine should be applied till analgesia is fairly well established. Then the parts should be thoroughly lubricated with vaseline, and the tips of three or four fingers of each hand applied to the purple projections. Steady pressure is to be applied, while the patient is ordered to press down as he does in the defecation of hardened feces. Instinctively, and almost invariably, he shrinks and draws away from the pressure on the painful swellings, at the same time puckering the already too contracted anal orifice. But when he is made to comprehend that puckering renders reduction impossible, while resolute and persistent straining down relaxes and opens the orifice and allows the swellings to be forced back into the rectum, often semi-instantaneously, he will govern himself accordingly. Sometimes the performance can be terminated more speedily by having the patient assume a squatting posture, after the preliminaries have been attended to. Then the straining down seems to be more thorough and efficient, and the piles, liberated from constriction, slide homeward with little compulsion.

"This is the facile reduction of prolapsed hemorrhoids; and the patient can be taught to accomplish it early and easily without the aid of the physician."

The Old Country Doctor.—The following pen picture is taken from *The Christian Herald*, the journal edited by the Rev. Dr. Talmage. It is not signed with his name, but it bears an exceedingly close resemblance to his writing. Especially worthy of the eloquent divine is his peroration, where he says of the overworked old country doctor: "He deserves every kindness at our hands."

"Our country physicians," says he, "have so many hardships, so many interruptions, so many annoyances, I am glad they have so many encouragements. All doors open to them. They are welcome to mansion and to cot. Little children shout when they see them coming down the road, and the aged, recognizing the step, look up and say, 'Doctor, is that you?' They stand between our families and the grave, fighting back the troops of disorder that come up from their encampment by the cold river. No one hears such thanks as the doctor hears. They are eyes to the blind, they are feet to the lame, their path is strewn with the benedictions of those whom they have befriended. One day there was a dreadful foreboding in our house. All hope was gone. The doctor came four times that day. The children put away their toys and all walked on tiptoe, and at the least sound said 'Hush!' How loudly the clock did tick, and how the banister creaked though we tried to keep it so still! That night the doctor stayed all night. He concentrated all his skill upon the sufferer. At last the restlessness of

the sufferer subsided in a calm, sweet slumber, and the doctor looked up and smiled, and said: 'The crisis is passed.' When propped up with pillows, in the easy chair, she sat, and the south wind tried to blow a rose-leaf into the faded cheek, and the children brought flowers—the one a red clover top, the other a violet from the lawn—to the lap of the convalescent, and Bertha stood on a high chair with a brush smoothing her mother's hair, and we were told in a day or two she might ride out, joy came back to our house.

"And as we helped the old country doctor into his gig, we noticed not that the step was broken, or the horse stiff in the knees, and we all realized for the first time in our life what doctors were worth. Encourage them. They deserve every kindness at our hands."

The Bhau Daji Treatment of Leprosy.—In the *British Journal of Dermatology* for July Mr. Stanley Boyd says:

"Mr. Bhau Daji was a graduate of the Grant Medical College, Bombay. I am informed that one of his teachers, the well-known Dr. C. Morehead, suggested to him that he should study the treatment of leprosy. Accordingly Bhau Daji began a series of careful observations upon the various remedies which had a reputation among the natives for the relief of leprosy. He commenced work upon the subject before 1859, when Dr. Morehead left India, and, in 1862, I find a note of his having stated to Dr. Duff, of Calcutta, that he was trying a remedy in his 'charitable dispensary at Bombay which offered a hope even for lepers.'

"About 1868 letters from people who believed that they had been cured of leprosy by Bhau Daji began to appear in the Indian newspapers, and occasional articles in the *Times of India* show that there was a good deal of acrimonious discussion going on upon the subject of these 'cures,' and upon the propriety of Bhau Daji's action in keeping secret his method of treatment. Naturally medical men were very skeptical as to the reality of the cures, and the *Lancet*, 1868, vol. ii, p. 238—in the same volume which recorded Dr. Bakewell's report upon Beaupeithy's cases—stated that, among the seventy cases of relief or cure with which the Bhau Daji treatment was at that time credited, not one cure had been fairly proved, and expressed the opinion that the mode of treatment should be made known.

"Bhau Daji, however, made up his mind that the value of his remedy should be proved beyond a possibility of cavil before he made it public property, and the testing of a remedy for a chronic disease like leprosy would evidently require some years. He accordingly raised funds and established a hospital and dispensary for lepers. Here accurate records in the shape of notes, photographs, and drawings of the cases under treatment were kept. While engaged in this work, in January, 1873, he had an attack of apoplexy, from which he never recovered sufficiently to be able to work. He died on May 30, 1874, and it was generally believed that his secret had perished with him.

"I have been credibly assured that up to the time of Bhau Daji's death his own brother, Narayan Daji, did not know the name of the remedy. But, probably fearing that the value of his work might be lost, Bhau Daji had told it to three European friends, in confidence. This condition all felt to be binding, until one of them, a civil servant of high position, after inquiring from Bhau's executors and children whether they had any objection to his making the remedy known, placed the matter in my hands, giving me at the time a specimen of the remedy, his original pencil notes of several cases made on September 19, 1868, accounts of several other cases which appeared in print, copies of two statements sent by lepers to Bhau Daji, and certain letters from Bhau Daji himself. I ought to remark that the gentleman to whom I am indebted for most of my information was well qualified to make observations in such a matter. A judge by profession, and accustomed to deal with evidence of all kinds, he had recently passed through an all but complete course of study in a London medical school, and his interest in scientific matters of all kinds was well known in Bombay.

"On looking through the evidence, I felt sure that it would be insufficient to convince any one, because the observations recorded were not continued long enough to prove the relief or cure permanent. I therefore used every endeavor to discover what had become of Bhau Daji's papers, photographs, etc., at his death. They are said to have

passed to his brother, Narayan, who survived him only six months, but beyond this I have been unable to trace them. A short time ago, however, I was so fortunate as to discover that a boy who formed the best case of supposed cure in my collection is alive and well, earning his living as a carpenter; and I have received some valuable information concerning two other patients from Colonel Wilson, the present Commissioner of Police in Bombay, who was so good as to inquire after them for me. With these items in hand it seemed to me that I had sufficient evidence to justify me in bringing Bhau Daji's remedy prominently forward, and in asking those who have the opportunity to give it a trial. I hope further that some of the patients mentioned may still be traced and notes of them sent to the *British Journal of Dermatology*. In this paper I give the names and addresses of patients who wrote to the Bombay papers testifying to the value of Bhau Daji's treatment.

"With regard to the nature of the remedy: My informant told me that Bhau Daji came ultimately to rely upon one substance—the oil of the *Hydnocarpus incobrains*, known among the natives as kauti—which he used both for internal and external administration. Sometimes he colored the oil to render it less easily recognizable. I have statements of the directions given by Bhau Daji to two patients—one European, the other native. From these I gather that in the early morning at 8-8.30, of the oil was taken in boiled milk, and it is said to be 'not bad to the taste'; then the patient was rubbed all over with the oil; after two hours the oil was washed off in a warm bath. Sometimes the oil was directed to be applied again, and kept on until evening, when the patient wiped himself and went for a walk until he perspired; in other cases no oil was applied after the warm bath until evening, when it was again rubbed in over the whole body, and the patient slept in it. The oil was applied also to affected mucous surfaces: for example, it was to be run into the nasal cavities. The patients were ordered to abstain from pork, beef, and fish; from all alcoholic drinks, tea and coffee; they were allowed as much milk, fruit, and vegetables as they liked; also butter, eggs, mutton, and fowl.

"No ill effects were noted in any case which I have come across. Irritation and vesication did not result. Some patients complained that it caused a sensation of hunger. A native clergyman recorded, from observations on himself and others, that the curative effects were best marked after one and a half to two months, when the swellings subsided, redness lessened, tubercles softened, and ulcers healed. Red or grayish spots, he said, assumed a dark hue and became black, then the skin turned to the colors natural to the patient."

The Prevention of Cholera.—At the recent meeting of the Medical Society of New Jersey Dr. D. C. English, chairman of the standing committee, presented the following hints to communities threatened with cholera:

1. Inquire into the sanitary administration in your community and give your most energetic efforts to secure its improvement.
2. Obtain the service of men of sterling character and superior executive ability as members of your board of health.
3. Require frequent inspections and scrupulous cleanliness of all places, public and private, particularly every street and alley; every sewer, drain, cesspool, vault, and pit; every dwelling, store, and office, including the plumbing; every yard, outhouse, and stable.
4. Cause all surface wells to be examined and close up those which are found to be polluted.
5. Establish or perfect a system for the daily removal and safe disposal, by fire if possible, of all garbage, sweepings, rags, and other domestic refuse.
6. Be prepared to skillfully and effectually disinfect, at public expense, all infected persons, clothing, baggage, vehicles, and premises. Cause a supply of standard disinfectants to be kept ready for use by the health authorities.
7. Exclude from the markets all unwholesome food.
8. Provide and keep in readiness a suitable hospital for communicable diseases, and make engagements with physicians and attendants in anticipation of the need of their services.
9. Instruct the people in regard to the nature of the disease; its mode of communicability; the value of thorough sanitation; how to live; what to eat; the importance of using recently cooked foods; the

necessity for boiling drinking water; the uselessness of deodorizers and the benefit to be derived from a liberal use of soap and water, and from pure air and sunshine.

10. Prevent the entrance of infected persons and effects into your community. Isolate every "suspect." Keep ready for reference Circular No. 45 of the New Jersey State Board of Health.

To arrest its spread after its first appearance in a community:

1. Provide competent employees to carry out rules and directions of physicians and board of health.
2. Promptly and completely isolate all cases of the disease, and also all "suspects."
3. Watch all apparently innocent diarrheas.
4. Thoroughly disinfect all choleraic discharges from patients before emptying into place of deposit. Completely disinfect all vessels, clothing, bedding, and everything used by the infected person or in the sick-room or house. Burn all garments and articles which are soiled by contact with the discharges.
5. In case of death of patient wrap the body in a sheet or blanket which is saturated with a solution of bichloride of mercury, 1 to 500, and pack the coffin full of quicklime. Bury the body privately, with no attendants except those necessary to insure proper burial at least five feet below the ground surface.
6. Give information to the public as to the existence and progress of the disease. Discourage popular fear. Provide free medical service for the poor and have it promptly rendered. Urge upon the people the greatest care in the selection of digestible food and its proper preparation by cooking; present the danger from the use of unboiled water; the advantage of avoiding all excesses. Especially urge upon the people the observance of the strictest cleanliness of person and surroundings.

Rudolf Virchow.—The *Lancet* for July 8th publishes the following address delivered before the San Francisco Medico-chirurgical Society by Dr. Levi C. Lane, professor of surgery in the Cooper Medical College:

"Among the names of men who have lived in the nineteenth century, and who are destined to live in human memory, is that of Rudolf Virchow. Most men who have earned distinction have done so by concentrating their energies in one direction; the striking characteristic of Virchow is that he has reached eminence along several lines, and so much so that had his labors been confined to any one of these he would still have made himself famous. Teacher, writer, pathologist, politician, each and all has he been, and in later years he has also been an investigator in anthropology and in archeology. The medical studies of Virchow were pursued in Berlin, where he had the great advantage of coming in contact with Johannes Müller, from whom he imbibed that inspiring enthusiasm for medicine which has since incessantly animated the receptive student. His successful career as a student soon indicated his fitness as teacher, and he would at once have been given a position in the faculty of the Frederic William University had he not at that time developed qualities which have ever since been predominant characteristics—viz., those of active political partisanship; in this rôle the part he has played has been a famous one, that of opponent to the policy of the Prussian Government, and this adverse position to the ruling power threw so many barriers in his way to advancement that he sought in Bavaria a more friendly field, and there he was honored with the professorship of medicine in the famous school of Würzburg, where he had once been student. At this period pathology was a field rich in truths awaiting the hand of discovery, although some work therein had been commenced, for observation had noted many facts; yet these lay without order in disjointed incoherence, ready for a master hand to unite them in logical sequence and to give them their true interpretation. The leading students and writers in England on this subject were James Paget and John Simon; forty years ago the writings of each of these were familiar to the medical reader. Much pioneer work had to be done before the pathologist could successfully labor, and this work was the task of anatomy. The anatomy of Galen where in error was revised by Vesalius, Eustachius, Fallopius, and others, whose researches were honored by their names being bestowed on some part of the human body. Each bone, muscle, nerve, and vessel

having been carefully studied, anatomical research appeared complete, when Bichat announced that these structures were susceptible of division into tissues. In the midst of the terrors of the French Revolution, in 1801, Bichat gave the medical world his remarkable work on anatomy, in which one finds the first systematic classification of the tissues composing the body. In its work of analysis, research passed from the tissues to their components; the hand of Bichat opened the way and pointed toward a new world—a world of the 'infinitely little,' as Pascal names the microscopic field which lies beneath man—in contrast to the immensely great one which lies above and beyond him. A great pioneer in the work of making necropsies and of observing and recording the changes of structure due to morbid action was John Baptist Morgagni, who wrote his observations in a famous book named *Adversaria Anatomica*, a copy of which I exhibit to you; the title literally signifies the daily jottings of anatomical observation. The *Lancet* many years ago adopted as a motto for its section headed 'A Mirror of Hospital Practice' the admirable lines of Morgagni, in which he says: 'There is no other certain way to know medicine except to have collected many histories of disease and of post-mortem examinations, of one's own work as well as that of others, and to compare these together.' The microscope, as an indispensable adjuvant in histological and pathological study, came into use slowly. The older generation was content with macroscopy; one generation ago the laboratory and the microscope came into general use.

"After a few years' connection with the school at Würzburg, Virchow was called to Berlin and made professor of pathology in the Frederic William University. During his connection with the Bavarian school he made himself a conspicuous figure in the medical world by the publication of an elaborate work entitled *Handbook of Special Pathology and Therapy*. Besides editing this work, Virchow was one of the most extensive contributors to it; it commences with a volume written by Virchow on The General Forms of Disturbance and Disease (in the body) and their Ways of Compensation. In this work the student will find one of the most exhaustive studies of the subject of inflammation. With the co-operation of a number of the leading medical writers of Germany, this encyclopædic work was continued for several years; among its writers may be mentioned Drs. Bamberger, Griesinger, Hasse, Lebert, Traube, and Hebra, each an authority on his subject. In his contributions to this work one catches glimpses of the future Virchow, especially in the chapters on Thrombus, Obstruction of Vessels, and Embolism. This encyclopædic work does not seem to have reached completion, although it contains seven large volumes. During its publication Virchow commenced his *Archives of Pathological Anatomy, Physiology, and Clinical Medicine*. In this journal papers on these subjects of great merit have appeared; in fact, the critical censorship of the eminent editor was such that the appearance of an article in the *Archives* was a guarantee of its excellence.

"In 1851 Virchow became one of the associate publishers of *Cantstatt's Jahresbericht*, a review of the progress of medicine in all parts of the world. This work consists of two large volumes, published annually, and containing a compend of what was published in each and every different language, during the preceding year, in every section of medicine. When in 1856 he was called to Berlin and given the appointment of professor of pathological anatomy in the Frederic William University he was thirty-six years of age, therefore in the prime of mental and physical vigor, and his connection with one of the first German universities offered him an opportunity for the exercise of his best powers as teacher, lecturer, and writer. To give him an ample sphere for the teaching of his specialty there was erected, under his supervision, it is said, a large building near the Charité Hospital, specially arranged for pathological work. In the winter of 1857 to 1858 this building was rendered famous by the delivery of twenty lectures, in which Virchow elaborated and presented his doctrines of cellular pathology. These lectures, of which there is a good English translation, introduced a new era in medicine; in a style singularly attractive they gave to pathology a definite and enduring form, depicting the changes which disease impresses on the tissues, the constituent cell being the prime factor in all the morbid processes. The connective tissue, hitherto viewed as an unimportant or inert contingent of animal structure, was by Virchow first shown to have most invaluable func-

tions as an agent of repair, furnishing elements for the restoration to integrity of diseased or injured parts; while, as a neoplastic factor, the cell, whether of connective tissue or of epithelial origin, was shown to be the leading agent in the development of sarcoma, carcinoma, and other growths. Although subsequent research has rendered necessary a revision of some points of these doctrines, yet, in the main, they remain in integrity despite the efforts of some who would fain subvert them. The publication in 1858 of *Cellular Pathology* was followed in 1863 by one of equal eminence—viz., the *Pathology of Tumors*; the latter may be considered as the supplementary completion of the former. The pathology of tumors was also delivered within a period of five months as a series of lectures to an audience of students and physicians, and only one with untiring diligence and supreme capabilities for work would, as Virchow was then situated, have undertaken such a task. He acknowledges that without the aid of the stenographer, who copied the lectures, the work would have been impossible. The labors of Virchow have not been confined to scientific work; he is a friend to popular instruction and has liberally contributed his quota in that direction. A few years ago, in conjunction with Fr. von Holzendorff, he commenced the publication of a series of addresses in popular form on subjects within the domain of literature, history, medicine, and natural science. To-day the work has nearly reached the number of seven hundred addresses; those which have relation to medicine or to natural science have been supervised by Virchow. Although these addresses are popular in character, they have yet been prepared by their respective writers with such care that the educated reader will be repaid for the perusal of any of them.

"To what has already been mentioned, Virchow has added other literary work, consisting of memorial addresses, papers on public hygiene, and on topics kindred to medicine; here, especially in the addresses on Schönlein, Müller, and on Goethe as a naturalist, he has given evidence that his pen is at home in a field far removed from the pathological. Virchow took an active part in the deliberations of the famous association founded by Oken and named the 'Society of German Naturalists and Physicians.' Before this society he delivered, in 1865, an address entitled *The Importance of the Natural Sciences and their Development in Germany*. In 1890, when the International Medical Congress met at Berlin, by unanimous consent of the medical profession of Germany, Virchow was selected without a challenging rival as the one most worthy of the coveted position of presiding over that body, and the chaplet then placed on his brow was stirred by no breath of envy, since it had the sanction of the medical men of all nations.

"By mental constitution Virchow is a controversialist; by precept and by practice he has taught that unless a man when unjustly attacked defends himself, he is lacking in duty; besides the defensive he has also taken a boldly aggressive part in scientific and in political assemblies. One of the noblest efforts of Virchow's intellectual life is an address delivered ten weeks ago before the Royal Society of England. The subject was the 'Position of Pathology among the Biological Sciences.' Though delivered from the rostrum where Faraday, Huxley, Tyndall, Buckle, and other representatives of the best intellect of England had stood, no abler address had ever been delivered there. It was an offering at a noble shrine of the best fruits of one of the ablest and most thoroughly trained minds within the domain of medicine. In English as polished as his native Teutonic, and with a modesty which is ever the close companion of greatness, in simple and almost impersonal terms he recounted his services to the science of medicine. Virchow has made the whole medical profession heirs of his doctrine, but his lines of work and methods of research have been pursued with especial zeal by some of his pupils. Among these may be mentioned Recklinghausen, Wegner, Orth, and Grauwitz.

"I first saw Virchow at his practical course in the post-mortem room; he entered in haste, almost breathless, and at once proceeded to his subject. The cadaver, frozen and in a room ice cold, was examined according to the plan laid down in his manual entitled *Sections-Technik*. In the use of his special knife, which he called the 'pathologist's sword,' he displayed wonderful expertness and faultless accuracy. Holding the brain in one hand he cleaves it in parallel planes, so that it is divided into many thin lamellæ, which, like a book, can be opened

and closed at any point, and the whole can afterward be replaced in the cranium with but little signs of mutilation. Thus proceeding, disease at any point can be discovered. On one occasion the head of a horse that had died of glanders was the specimen chiefly considered; this head, sawed through longitudinally so as to present the nasal cavities studded with ulcers, lay for an hour before him while he discussed the pathology of glanders. When the fatal character of the disease is considered, it is evident there was no small risk in thus standing over and breathing the effluvia from such a source of fatal contagion. How accurate was his knowledge of the parts he was to consider in his demonstration was shown on one occasion, when, for the purpose of microscopic work, I had removed the merest fragment from a cerebellum. He instantly detected it, stopped in his lecture, and administered a reproof to the unknown marauder. Carelessness or inattention on the part of the student was at once observed and often chided. One whose eyes wandered through the window to something outside was notified that if he saw anything more interesting than the lecture he had better retire.

"Time is all too short for Virchow; for the completion of the work he always has on hand the day should number more than twenty-four hours. Not infrequently he spoke three times in one day; once I heard him lecture in the forenoon and deliver a long political speech in the evening, and in the afternoon of the same day he was engaged in sharp debate in the Reichstag; and all this while carrying on the writings before mentioned. Political life evidently has a fascination for him, for while these lines are being penned the telegram comes that he is a candidate for re-election to the House of Representatives. As a speaker Virchow is exceedingly calm and deliberate, and whether before a class of students or a political club he is never carried away by the 'torrent, tempest, and whirlpool of passion,' but his uttered sentences, scarcely distinguishable from his written ones, are clear, forcible, logical, and convincing. In person Virchow is of average stature, his expression is that of extraordinary courage; his attention once drawn to you you feel as if he were fixing you in focus on the object-glass of his mental microscope. A few years ago the French Government, on the occasion of the death of Claude Bernard, deputed Gambetta to pronounce an *éloge* on the great scientist. This oration, replete with supreme eloquence, closed with the remarkable words: 'We now offer our salutations to Claude Bernard on his entrance into immortality.' The hand of Death had then closed the door against Envy; but a few months ago the world was witness of still greater salutations which greeted the ear of one still living; men of all tongues and all climes where medicine is a cultivated science sent gifts, offerings, and congratulations to Virchow on the anniversary of his seventieth birthday. Among the offerings was a medalion of gold, the coinage of the gifts of many friendly hands. But as form chiseled from marble and feature limned by the pencil are perishable, these gifts of art were surpassed by another offering; this was a sheaf harvested from the best fields of German medicine, composed of fascicles written by hands trained by the great teacher. This offering, 'the enduring produce of immortal mind,' was the most noble and imperishable of all, since it was wrought by the merciful hand of Medicine; and, besides homage to the master, it contained a solace to pain and disease, a perpetual heritage of our race."

Ganglionic Fever.—Moussous (*Rev. mens. d. mal. de l'enf.*, June, 1893) considers that the suggestion of Pfeiffer and Starck that there is a special form of fever affecting children from two to twelve years old, and characterized by enlargement of cervical glands, is useful, since it classes apart certain cases of fever in children in which the course is short and the prognosis good, although the symptoms for a time suggest tuberculosis or typhoid fever. The patient suddenly, or after a few days of *malaise*, begins to suffer from pain in the neck, headache, depression, and nausea and vomiting. It is found that the temperature is elevated, and that the glands in the submaxillary region, and behind the sterno-mastoid, and at the back of the neck, all or any, and generally on both sides, are swollen and tender. Frequently in the early stage the buccal mucous membrane is very red, but no active inflammatory condition of the pharynx or tonsils is to be detected. All symptoms may disappear in a few days, or the fever may persist and the pa-

tient begin to suffer from paroxysmal cough resembling whooping-cough, or from pain about the umbilicus, or from both. In some cases the liver and spleen are enlarged. Constipation is a constant symptom, and Starck suggests that the disturbance is due to absorption of poisonous material from the retained feces. Moussous is inclined to attribute more importance to the reddening of the buccal mucous membrane, supposing that it is due to infection by some pathogenic microbe which later infects the ganglionic system. The symptoms may continue for days after the constipation has been relieved. The paroxysmal cough is attributed to enlargement of the tracheo-bronchial glands, and in the two cases he records Moussous was able to detect dullness and harsh respiration in the interscapular regions. The belly-ache is attributed to the extension of the inflammatory affection to the abdominal lymphatics. Treatment has not appeared to have much effect on the course of the illness, and Moussous suggests that the pathology of the disease is not the same in all cases.—*British Medical Journal*.

To Contributors and Correspondents.—The attention of all who purpose favoring us with communications is respectfully called to the following:

Authors of articles intended for publication under the head of "original contributions" are respectfully informed that, in accepting such articles, we always do so with the understanding that the following conditions are to be observed: (1) when a manuscript is sent to this journal, a similar manuscript or any abstract thereof must not be or have been sent to any other periodical, unless we are specially notified of the fact at the time the article is sent to us; (2) accepted articles are subject to the customary rules of editorial revision, and will be published as promptly as our other engagements will admit of—we can not engage to publish an article in any specified issue; (3) any conditions which an author wishes complied with must be distinctly stated in a communication accompanying the manuscript, and no new conditions can be considered after the manuscript has been put into the type-setters' hands. We are often constrained to decline articles which, although they may be creditable to their authors, are not suitable for publication in this journal, either because they are too long, or are loaded with tabular matter or prolix histories of cases, or deal with subjects of little interest to the medical profession at large. We can not enter into any correspondence concerning our reasons for declining an article.

All letters, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication. No attention will be paid to anonymous communications. Hereafter, correspondents asking for information that we are capable of giving, and that can properly be given in this journal, will be answered by number, a private communication being previously sent to each correspondent informing him under what number the answer to his note is to be looked for. All communications not intended for publication under the author's name are treated as strictly confidential. We can not give advice to laymen as to particular cases or recommend individual practitioners.

Secretaries of medical societies will confer a favor by keeping us informed of the dates of their societies' regular meetings. Brief notifications of matters that are expected to come up at particular meetings will be inserted when they are received in time.

Newspapers and other publications containing matter which the person sending them desires to bring to our notice should be marked. Members of the profession who send us information of matters of interest to our readers will be considered as doing them and us a favor, and, if the space at our command admits of it, we shall take pleasure in inserting the substance of such communications.

All communications intended for the editor should be addressed to him in care of the publishers.

All communications relating to the business of the journal should be addressed to the publishers.

Contributors who wish to order REPRINTS of their articles should do so on a blank prepared for that purpose, which will be sent to them by the publishers on receipt of a request to that effect. The order should be sent to the publishers, and not to the editor.

REASONS FOR THE
REMOVAL OF ABDOMINAL TUMORS.

By F. BYRON ROBINSON, B. S., M. D.,

CHICAGO.

PROFESSOR OF GYNÆCOLOGY IN THE CHICAGO POST-GRADUATE SCHOOL;
GYNÆCOLOGIST TO THE WOMAN'S HOSPITAL, TO THE POST-GRADUATE HOSPITAL,
TO CHARITY HOSPITAL, AND TO COLUMBIA DISPENSARY HOSPITAL.

(Continued from page 66.)

Abdominal Tumors produce Kidney Disease.—The kidney, in proportion to its size, has the highest nerve and blood supply of any viscus except the uterus. According to the recent investigations at Johns Hopkins University, the kidney is supplied only by sympathetic nerves. It is a common observation that abdominal tumors are followed by kidney disturbances; even the gravid uterus does not allow the kidney to escape its irritation. The kidney disease brought about by abdominal tumors is reflex. It is a physiological principle that an influence acting through the nerves alone can arrest all secretion. Minor degrees of irritation will suffice to increase, diminish, or change the kidney secretions. An irritation continued on an organ indefinitely and modifying its action may be sufficient to induce disease. Kidney disease resulting from abdominal tumors, from the very nature of the case, is chiefly chronic. The first point to consider as the initial step in chronic renal disease from abdominal tumors is partial or complete obstruction of urine flow from Bowman's capsule to the end of the urethra.

The second point to consider in chronic renal disease due to abdominal tumors is reflex irritation from distant viscera.

The third point of consideration in renal disease due to abdominal tumors is infection. As regards the first point—*obstruction*—the location and size of the tumor must be noted. A partially occluded ureter, through long-continued pressure, will cause renal disease. Under this head would be classed mechanical impediments to the flow of urine.

If the obstruction is sufficient it will create hydronephrosis. If the hydronephrosis is long enough maintained the kidney will secrete until blood pressure is acquired, and then in a few months atrophy.

The writer has proved by experiments on the dog's ureter that a ureter completely ligated will shrink a kidney to about one fifth its original size in five months.

The pressure of the tumor on the ureter is a silent process not often recognized by the attendant. The obstruction of the ureter is like the quietly growing intestinal stricture, which is rarely recognized until some terrible disaster reveals a long series of old pathological conditions. The main idea in the obstruction, however, is that it is partial, and by raising the difficulty of urine flow renal elimination becomes deficient. The blood then becomes waste-laden. If the obstruction is sufficient the result will be hydronephrosis, and being long continued (without in-

fection), the result is renal atrophy, as the writer proved by tying the dog's ureter.

The second point—*reflex irritation*—is more significant because it means that irritation from any viscus can be reflected on to the kidney over the renal plexus. The abdominal tumor irritates some contiguous viscus; the irritation quickly passes to the abdominal brain by way of the sympathetic plexus of said viscus, where the forces are re-organized and transmitted to the kidney. There is little doubt that the sudden rise of temperature from passing a sound into a man's bladder is due to reflex irritation transmitted from an oversensitive urethra. It is probable that the so-called urinary fever is reflex. It modifies circulation by inducing local anæmia and local hyperæmia. In this way nutrition quickly changes. Samples may be seen in strictures of the intestine or ureter where the walls above the stricture are greatly thickened. Reflex irritation from the tumor is important, as it alters renal secretion. The renal secretion may be (a) excessive, (b) decreased, or (c) disproportionate.

The chief point in regard to secretions in patients with abdominal tumors is a decreased or disproportionate secretion. It is common to observe a patient with a tumor to secrete a small quantity of urine heavily laden with salts. The amount of urine voided at times appears as an alarmingly small quantity. Natural reasoning from physiological and clinical bases attributes the decreased quantity of urine to the irritation from the tumor transmitted over the renal plexus. But autopsies on women who die of tumors prove it beyond the shadow of a doubt.

Disproportionate renal secretion from the irritation of abdominal tumors is also common. Albumin is the chief element found. But phosphates, urates, or sugar make up the varying scales of salts. Even the amount of water will vary within short limits.

The tumor from pregnancy is a common sample of disturbed renal secretions due to reflex action. Thus deranged renal secretion is frequently due to reflex irritation, depending on the presence of an abdominal tumor. The change in the secretion consists in increase, decrease, or disproportionate quantities. As each organ has its own distinct nerve plexus, so it should be understood that reflex action is carried along distinct anatomical lines.

As regards the third point—*infection*—in chronic renal disease from the presence of abdominal tumors a serious field appears.

The genito-urinary tract can be infected at any point from kidney cortex to urethral end. If the tumor presses severely enough on the urinary tract, a perforation will occur, and from this perforation infection will travel in either direction—toward the urethra or toward the kidney.

The result of perforation of the urinal tract will be nephritis and cystitis. The perforation is most likely to occur in the bladder, from which the infection ascends the ureters to the kidney. It is not necessary to have a large tumor to perforate the urinal tract; simply a suppurating focus is sufficient. It is not necessary to have a complete perforation of the urinal tract to allow infection to gain an

entrance, for the germs or their products (ptomaines) may penetrate a thin pathological wall. The final result of an infected urinary tract is urethritis, with parenchymatous or interstitial nephritis. The writer has observed some disastrous results from pyosalpinx perforating the bladder and intestines. It may here be noted that Doran, a most excellent observer, made post-mortem examinations of forty women who had died of ovarian tumors, and thirty-two had severe kidney disease. This means that eighty per cent. who died from ovarian tumors had kidney disease. No doubt the kidneys were diseased from the presence of the tumors. Obstruction, reflex action, or infection told the tale of renal disease from the tumors.

A good sample of obstruction, reflex irritation, and infection of the urinary tract is seen in cases of gonorrhœa in men which end in stricture and "catheter life." The stricture gradually arises in the urethra and marks the onset of obstruction to the urinary flow. This increasing obstruction induces constant reflex irritation, and yet the man is not subjectively or objectively sick. But now he begins "catheter life," which means infection. It means self-destruction by his own hands. Thus to obstruction and reflex irritation of the urethra he has added the fateful infection carried on his catheter, which too frequently makes the fatal march swiftly onward and swiftly downward.

The kidney suffers similarly from any abdominal tumor and chiefly by reflex irritation which passes from the abdominal brain by way of the contiguous plexus, where it is recognized and emitted on the large renal plexus to the kidney. The writer notes that those women who come to him for the purpose of having tumors removed have a very variable quantity of urea in the urine. At the Woman's Hospital the writer has the urea tested in every case of laparotomy, and the amount varies from five to eleven grains to the ounce. The tumor appears to play a significant rôle on the production of varying quantities of urea.

Abdominal Tumors produce Disease of the Digestive Tract.—It is probable that secreting or glandular organs suffer the most from abdominal tumors, because the main damage is through reflex action and the glands are the most highly supplied with (sympathetic) nerves. The digestive tract should be studied by means of (a) sensation, (b) motion, and (c) secretion. The slow, continuous pressure of abdominal tumors produces but little recognizable sensations from the digestive tract. Another point arises that from inexperience the patient can not localize the pain in the digestive tract, but refers it mostly to the abdominal brain; so that subjective sensations in the digestive tract due to tumors are of small value. As regards motion in the digestive tract in cases of abdominal tumors, one can say that in the great majority of fair or large-sized tumors motion is diminished and constipation is the rule. But the main study of damage of abdominal tumors on the digestive tract will be through the secretions. The secretions are altered in three ways: (a) they may be excessive, (b) they may be decreased, or (c) they may be disproportionate.

The final result is indigestion. The irritation from the tumor is carried on the plexus of any contiguous viscus to the abdominal brain, where it is reorganized and emitted

to the digestive tract over the gastric plexus, the superior mesenteric plexus, and the inferior mesenteric plexus. In any case the brunt of the forces end in the ganglia which lie just below the mucous membrane. The ganglia constitute what is known as Meissner's plexus, which rules secretion. If the irritation be of such a nature as to produce excessive secretion, diarrhœa may result. The excessive secretion will decompose and induce malnutrition.

It is common to observe in women with tumors spells of indigestion, and especially in times of excessive irritability. No doubt at such times the irritation assumes a prominence not experienced on other occasions. If the irritation is of such a nature as to decrease secretion, constipation will likely result. An inactive digestive tract is the forerunner of non elimination and a waste-laden blood. It is common to observe women with tumors to have almost no appetite for weeks at a time accompanied by constipation. No doubt the main chapter in altered secretion consists in what may be termed disproportionate secretions. The elements which make up the digestive fluid are not secreted in normal quantities; one element is deficient and another is excessive. The normal relations of acidity and alkalinity are changed so that constant fermentation arises. Again, from the irritation of an abdominal tumor individual organs do not secrete their normal quantity or quality.

The liver may secrete excessively or deficiently. The pancreas may do too much or too little. The irritation may cause segments of the alimentary canal to secrete excessively or deficiently and thus destroy the finely balanced secretion of the canal as a whole. The stomach or small intestine may by the irregular irritation do too much or too little or act irregularly. This produces decomposition in the fluid and fermentation results; such women are continually troubled with "wind on the stomach." Diarrhœa and constipation quickly alternate and the result is frequent attacks of acute indigestion.

Disproportionate secretion is the most frequent and disastrous, because the irritation from the tumor is irregular. It storms one day and sleeps the next. But the nature of irritation is to be inconstant and to rush pell-mell over the nerve plexuses or to assume a profound quietude. Irritation scampering over the plexuses month after month is sure to be followed by indigestion, malnutrition, anæmia, and the final ending of the poor patient is neurosis.

The subject of pressure of abdominal tumors on the digestive tract may here be considered. The effect of pressure acts in two directions—(a) on the alimentary canal and (b) on the tumor itself. The effect on the canal may be (a) to derange the secretion and motion of the segment pressed on; (b) to perforate the canal; (c) to obstruct the canal. The more serious effect of the tumor pressure on the digestive tract arises from the changes which result in the tumor itself. The changes arising in the tumor from the alimentary canal are: (a) inflammation, (b) adhesion, (c) suppuration, and (d) rupture. The main idea is that infection or its product (ptomaines) enters the tumor through the gut wall.

It frequently happens in laparotomy that some part of

the digestive tract is found firmly adherent to the tumor. The cause of this adhesion is the formation of exudates into organized tissue which binds the gut wall and tumor together. The irritation from the contact of the gut wall and tumor induces the passage of germs or their products (ptomaines) through the wall of the intestine, which gives rise to an exudate. The writer has fully satisfied himself that considerable inflammation, adhesion, and suppuration, which are found to exist in tumors, are due to the passage of the morbid matter through the intestinal canal.

It is not uncommon that one finds the gut attached to a tumor firmly from an inch to a foot in length when the great gateways of infection, the tubes, show no traces either ancient or recent. The vermiform appendix is a certain source of infection not only in abdominal tumors, but also is the source of much infection of the genital organs.

Considerable inflammation and adhesion of intestines (and occasionally other organs) when abdominal tumors exist is accounted for by infection passing through the gut wall into the tumor. As regards suppuration in abdominal tumors, due to infection arising from the alimentary canal, it may be said that suppuration is only a stage in advance of inflammation, and that inflammation is only a degree short of suppuration. So that in one sense they are the same process. In the case of inflammation the white blood-corpuscles have conquered the invaders and resented further progress, while in suppuration the invading infection destroys whole fields of vital tissue, leaving focuses of local death—necrosis. The pus formed by these infections through the gut wall may be safely evacuated by way of the alimentary canal. But frequent fatal issues follow either rapidly or through long exhausting processes.

The sympathetic pathological course which abdominal tumors induce in women are: (1) Irritation; (2) indigestion; (3) malnutrition; (4) anæmia; and (5) neurosis. The irritation passes by reflex action to the digestive tract (including the liver and pancreas). The irritation destroys in the digestive tract (*a*) the rhythm of the liver, pancreas, and alimentary canal by emitting irregular forces over the plexuses at irregular periods. The reflex action has no regard for rhythm. (*b*) The irritation produced by the tumor on the canal destroys its motion; (*c*) it destroys its sensation; (*d*) it destroys its normal secretion.

Indigestion is a natural result of imperfect rhythm, motion, sensation, and secretion of the alimentary canal. Long-continued indigestion results in malnutrition; malnutrition finally ends in anæmia. In anæmia the fluid tissue known as blood is deficient in its proportional constituents, and the innumerable nerve ganglia being bathed in waste-laden and impoverished blood, finally reduces the woman to an irritable condition or a neurosis.

(To be concluded.)

"Physiological Examinations of School Children of Washington are being made in order to determine the comparative rates of growth, influence of nationality, school hygiene, density of population, systems of physical culture, etc. Special measurements of the nervous system with the æsthesiometer, dynamometer, baræsthesiometer, and thermæsthesiometer are being made by Dr. MacDonald, to estimate the proper amount of study required, the proper age of advancement, etc."—*Medical News*.

A CASE OF ACUTE EMPYEMA OF THE ANTRUM OF HIGHMORE OF NASAL ORIGIN.

By JULIUS WOLFENSTEIN, M. D.,
CLEVELAND, OHIO.

MR. H., aged about thirty, consulted me on April 26, 1893. The patient states that he caught a severe cold in his head two weeks ago which ran an ordinary course until within the past three days, when he noticed soreness of the teeth and pain in the cheek of the left side. At the same time there was also a profuse discharge of pus from the left side of the nose. There is also a feeling of soreness in this side of the nose. The pain on the left side of the face is considerable, especially at night.

On examination, the right side of the nose shows slight swelling and redness of the mucous membrane. On the left side the mucous membrane of the lower turbinated bone is so swollen that nothing of the interior of the nose can be seen. After an application of a twenty-five-per-cent. cocaine solution a considerable quantity of pus can be seen in the nose, particularly in the region of the middle turbinated bone. This is removed and the nose is thoroughly cleansed. The patient is made to lie on a lounge on the right side with his head toward the floor. After several minutes the patient is again examined, and pus can be seen coming from the middle meatus in the region of the ostium maxillare.

The test with the electric light in the mouth of the patient shows transillumination of the right side of the face. The left side is perfectly dark.

The patient was instructed to wash out his nose frequently with a solution of Seiler's tablets, and was given one fourth grain of codeine several times daily to relieve the pain.

May 1st.—The patient reports that the pain has almost entirely ceased and that the discharge from the nose is less. Examination of the nose shows lessening of the swelling and redness. The electric-light test shows beginning transillumination of the left side of the face. The same treatment is continued with the exception of the codeine administration.

15th.—There is still slight tenderness of the teeth and cheek. The discharge has entirely ceased for three days. Transillumination perfect on both sides. The patient was ordered to continue the washing out of his nose with the Seiler's tablets for several weeks. As the patient was compelled to leave the city at this time, I have not seen him since the last date, but I received a letter from him on May 26th, in which he states that he has had no further trouble to date, and that he feels perfectly well in every respect.

Acute empyema of the antrum of Highmore of nasal origin seems to be a rare affection, since little or no attention is given it in our modern text-books on diseases of the nose and its accessory cavities. Without any attempt at completeness in the review of the modern text-books on this subject, I will only quote two or three of the leading authorities on the subject to substantiate the correctness of this assertion.

Let us first take Voltolini, surely a high authority on the subject, for it is to him that we owe one of the diagnostic methods in empyema of the antrum—*i. e.*, the so-called "*Durchleuchtung*," or transillumination. In his work, *Die Krankheiten der Nase*, etc. (Breslau, 1888, p. 343), he makes no mention of acute empyema of the antrum of Highmore, and, further, he ignores the fact that this affec-

tion may be of nasal origin. He simply says that it is due "principally to diseased teeth or following their extraction."

Schech, whose well-known treatise on diseases of the nose is to-day considered as the very highest authority on rhinology both in Europe and America, mentions acute empyema of the antrum; but among the aetiological factors enumerated he does not include "catching cold"—that is, acute rhinitis—in the first two editions of his work, the second edition of which was published as late as 1888. In the last two editions of his excellent text-book he mentions briefly acute rhinitis as a possible cause of acute empyema of the antrum.

Bosworth, in his late work on *Diseases of the Nose and Naso-pharynx* (New York, 1889, pp. 465-479), treats of this subject rather indefinitely, and, while he admits the possibility of an acute empyema of the antrum as a consequence of acute rhinitis, he does not seem to be thoroughly convinced of the fact. He speaks as follows: "I think it is an exceedingly rare event that disease of this cavity (*i. e.*, the antrum) results by an extension of inflammation through continuity of tissue" (*op. cit.*, p. 466). And further: "An attack of acute rhinitis is not infrequently attended with symptoms referable to the maxillary sinus, and hence may be an exciting cause of suppurative disease of that cavity" (*op. cit.*, p. 468).

These two sentences appear to me, at least, to contradict each other. Bosworth first maintains that disease of the antrum, under which term naturally empyema is also included, is very rarely due to "inflammation through continuity of tissue." Then further in his article he asserts that acute rhinitis may be a cause of empyema of the antrum. As I understand the pathology of this affection, this can only occur by "inflammation through continuity of tissue." At least this is the generally accepted view of the modern authorities on this subject.

Without quoting any more authorities, the general consensus of opinion concerning the aetiology of empyema of the antrum seems to be that it is not often of nasal origin; and as regards the acute variety of this affection, most authors do not even mention a nasal origin. Those who do concede a nasal aetiology seem to have doubts on the subject, and very guardedly say it "may" occur.

This is the principal reason that I have detailed the above case: to draw the attention of the medical profession to the fact that acute empyema of the antrum of Highmore is not so rarely a result of an attack of acute rhinitis, and should be so considered in the therapeutic management of this affection.

Without going into any prolonged discussion of the whole subject of empyema of the antrum, I would like to call attention to a few points in the aetiology, diagnosis, and treatment of this disease which may prove interesting.

First, I would call attention to an excellent article on this subject by Browne, published in the May number, 1893, of the *Journal of Laryngology, Rhinology, and Otology* (Empyema of the Maxillary Sinus, etc., pp. 214-221). This excellent article gives, with few exceptions, the

views held on this subject to-day, and its perusal can be highly recommended to all who wish to be informed on this subject.

In this article Browne asserts that empyema of the antrum is often due to "catching cold," and, further, he claims that in several cases the symptoms of the affection led him to believe that the empyema of the antrum "was primary to and independent of, if not causative to, the inflammation of the nasal mucous membrane" (*loc. cit.*, p. 215.) While I certainly do not doubt the accuracy of Browne's observations, I believe he stands alone to-day in his conclusions that acute empyema of the antrum of Highmore due to acute rhinitis may be a primary inflammation and not secondary to already existing nasal pathological conditions. Hence his assertion must be accepted with some pardonable doubt, at least until further corroboration by additional well-observed cases of similar nature.

Browne certainly takes the correct standpoint in maintaining that acute empyema of the antrum is often the result of acute rhinitis. This is definitely proved in the case detailed by me above, but, contrary to Browne's opinion as to the primariness of the empyema and the secondariness of the nasal manifestations, the nasal symptoms existed fully ten days before any symptom of antral complication appeared. Another case, that of a colleague, came under my observation recently in which the ordinary nasal symptoms of an acute rhinitis were present fully two weeks before any symptoms of empyema of the antrum were present. I think with our present knowledge on the subject there is no reasonable doubt but that, firstly, empyema of the antrum of Highmore is often of nasal origin, and, secondly, that acute empyema of the antrum is not a rare affection, and is a secondary inflammation depending, in most cases, on acute inflammation of the nasal mucous membrane.

As regards the value of transillumination in the diagnosis of empyema of the antrum, I do not believe in condemning this diagnostic method, in the words of Schrötter, as "an elegant plaything," nor do I believe that it is as important an adjuvant in the diagnosis of empyema of the antrum as one would be led to believe from the writings of Voltolini, Heryng, and others. From my experience with transillumination, I do not consider it a "quite reliable diagnostic measure in antral disease" (Browne, *loc. cit.*, p. 218). In the case detailed it is true the transillumination test proved the presence of an empyema of the antrum undoubtedly, and with the amelioration of the condition and the lessening of the empyema the affected side became more and more transilluminated. But this case has in my hands been the exception to the rule, and I have very often found an absence of transillumination on one or the other side, or even on both sides, of the face where I was positive that there was no antral disease. This observation has also been made by many prominent rhinologists, and most of these observers could prove that, in many cases where a decided umbra was present on one or both sides of the face, upon opening of the antral cavity no pus was found. So that from a positive standpoint transillumina-

tion does not stand the test of practical application. In other words, there is not always empyema of the antrum present in a case in which the face is not transilluminated. It has been generally believed that the test of transillumination had at least a negative side which was of value. In the words of Ruault (quoted from Browne, *loc. cit.*, p. 217), "we can have opacity without empyema, but we can not have empyema without opacity." Even this statement of the value of transillumination no longer holds good. It is true it is rather rare, but it does not happen that empyema of the antrum is present, and, in spite of this fact, there is no opacity of the face.

In the case of a colleague, mentioned before, there were all the typical symptoms of an empyema of the antrum—the bright-yellow discharge from one side of the nose, pain in the cheek and teeth of the affected side, the presence of pus in the nose after cleansing the same, and then, allowing the patient to lie down for several minutes on the unaffected side with his head toward the floor—and still, to my great surprise, upon introduction of the incandescent electric light into the mouth of the patient, the affected side was most beautifully transilluminated, in fact, to a greater degree than the unaffected side.

Taking all this into consideration, it may be said that transillumination is of value in some cases to corroborate an already established diagnosis of empyema of the antrum, but that it can not be regarded as a reliable method in the diagnosis of antral empyema, particularly if the other well-known symptoms of this affection are absent.

I think its greatest value rests on the fact that in cases of well-established antral empyema we can judge of the progress of the disease, particularly of an amelioration of the condition, by the increasing transparency of the tissues, which is in direct proportion to their more or less normal condition. This same view is also entertained in the article by Browne (*loc. cit.*, p. 219). Hence transillumination is of more value as an element in the prognosis than as a method in the diagnosis of antral empyema.

In conclusion, I would add a few words as to the treatment of acute antral empyema of nasal origin. I do not pretend to draw any definite conclusions from one or two cases, nor do I wish to use that often fallacious method of argument of *post hoc, ergo propter hoc*. In the case mentioned frequent washings of the nose with an alkaline and antiseptic solution resulted in a cure of the empyema in two weeks. I do not maintain that the empyema disappeared so rapidly as a direct consequence of the treatment, but I do believe that in acute empyema of the antrum of nasal origin simple remedies should be tried first. To keep the nose clean and to guard the patient against any further extension of the nasal and antral inflammation seem to me to be the indications which should be followed in the treatment of such a case. Should there be no improvement in two or three weeks, then the more radical surgical measures are indicated. But the antrum should not be opened in a case of acute empyema of nasal origin until the simpler remedies have been given a fair trial.

THE NEUROLOGICAL CAUSES OF IMPOTENCE.

By ARTHUR CONKLIN BRUSH, M. D.,

BROOKLYN,
ASSISTANT NEUROLOGIST TO THE KINGS COUNTY HOSPITAL;
NEUROLOGIST TO THE BROOKLYN CENTRAL DISPENSARY.

The sexual act in man is usually described as being composite, containing both mental and physical factors, but in reality psychological acts are probably just as much the result of physical structure as any other function of the body, and therefore such a division does not in reality exist.

An impression produced upon one of the senses is carried inward to the ganglionic cells at the base of the brain or in the cord, and here may be at once arrested and reflected outward, or it may pass upward to the controlling or ideational centers of the cerebral cortex. The former happens when from lack of development, as in infants and idiots, or when through sleep or disease the controlling centers are inactive.

After we have learned to associate the different impressions thus produced by an object, we have formed an idea of it, and, after an idea is once so formed, the excitation of any one of the impressions of which it is composed is sufficient to call the rest into being.

Ideas in like manner become associated into groups forming trains of thought; the presence of one idea in the mind calling up another with which it is habitually associated, and which thus seem to spring into consciousness of their own accord.

In other words, thought is nothing but another expression of the reflex action of the nervous system, in which, when certain groups of cells have become accustomed to act together, the excitation of any one of them calls the rest into activity. The more often such an action takes place, the more easily, the more rapidly, and the more unconsciously it is done.

An impression thus conveyed to the ideational centers may there be perceived or become potential. We only habitually perceive impressions, unless they be very decided, which are in accord with the ideas which are at that time occupying the mind; but it is probable that no impression produced upon the cortical cells is ever lost, but it may be years before associated ideas recall it to consciousness.

This is especially marked in dreams where past and forgotten events start up; but here, by reason of the accustomed paths of ideas being dissociated through certain ones being at rest, they become associated in an abnormal manner, closely approaching the delirium of mania. Ideas, trains of thought, mental peculiarities may be inherited just as other physical ones are. In other words, we inherit certain groupings of nerve cells, which may then be modified by the individual's surroundings.

Ideas may arise in the mind from the promptings of the bodily organs, each of which has undoubtedly its controlling center in the brain, the disturbance of which modifies the tone of the mind or may even produce so much disturbance as to give rise to insanity.

What the influence of each organ is on the mind is unknown, for, with the exception of the genital organs, they

are all active at birth. It is in the genitals alone that we have the chance of observing the effect produced upon the mind from non-development of an organ; but this, like that of disease of the organs, is usually marked.

For purposes of study we may consider the genital system to be composed of three parts—the external genitals, the spinal center, and the cortical center—and it is with the disturbances of these last two that I wish to treat.

Before puberty both the spinal and cortical genital centers are incompletely developed, but still possess some functional activity. Involuntary erections occur in both young animals and children, and, with the exception of the first few years, children have a more or less complete idea of sexual matters, even when they can by no possibility have derived them from their surroundings. These inherited ideas are apt to undergo further development from association or the discovery that handling the organs gives pleasure.

When the time of puberty arrives the sexual centers enter into a more active condition. The cells begin to store up power in a potential form, which, when it has reached a certain degree of tension, gives rise to irritability and, if this be carried beyond a certain degree, to an explosion of force.

The two centers mutually react upon each other, but the cortical possesses a more or less complete inhibitory control over the spinal, and it is not until its cells become irritated to such a degree that their action becomes disordered or delirious that this power is lost and the lower center allowed to discharge itself. Irritation of the cortical center, then, may be produced in two ways—either through impressions conveyed by the special senses, or by reflex irritation due to irritability of the spinal centers, and at such times thoughts on sexual matters enter the mind without regard to our surroundings; and if the state occurs during sleep, when the inhibitory power of the supreme center is in abeyance, an explosion is apt to occur. The reflex irritation is, however, usually sufficient to cause a partial awakening of the cortical centers and more or less incoherent ideas enter the mind, forming a dream.

So great is the mental disturbance which occurs at puberty that insanity sometimes occurs, and even the healthy mind develops an emotional tone.

Impotence from nervous causes may be due to four conditions—to want of development, to exhaustion, to irritable weakness, and to perversion. In failure of development of the spinal center, the patient has the perfect development of the genital organs and ideas, but lacks completely the power of erection. Niemeyer gives the history of such a case: A man, aged thirty; strong and muscular. Genitals large and well developed. This patient never had an erection, and was divorced after being married one year.

Failure in development of the cortical center occurs as a part of the want of cerebral development in idiots, but I have been unable to find the history of any case in which it existed with normal development of the other centers, unless we class with these cases those women who seem to be totally without sensual ideas; but such a condition is perfectly possible just as it occurs with the other centers.

Removal of the testes before puberty is followed not only by an arrest of development, but by retrograde changes in both centers. Erections no longer take place and the mind of the individual becomes affected. "He becomes cunning, deceitful, destitute of moral sentiment, and his mental and bodily powers are impaired." Removal after puberty seems to have much less marked effect. Usually there is little or no mental change, and the power of erection may persist and even be exaggerated.

Exhaustion of the cortical center shows itself by loss of its inhibitory power over the spinal, as a result of which the spinal center discharges itself almost as soon as irritated, and producing little or no mental excitement in the patient; an orgasm occurring as soon as an erection has taken place, or even before.

A case of this kind was brought to me at the Brooklyn City Dispensary: A boy, aged sixteen years; habitual masturbator, in whom the slightest attempt to touch the penis produced an immediate erection and discharge without giving any feeling of pleasure to the boy. Exhaustion of the spinal center shows itself by the patient having the desire without the power of erection or orgasm. This condition must not be mistaken for those cases in which the loss of power of erection is due to local conditions of the genitals. These cases are very common and may be purely functional as the result of fright or overanxiety.

Impotence from premature discharge of the spermatic fluid may occur from the excessive irritability of the cells of either one or both centers. This may be due to two opposite causes: to prolonged continence, causing the cells to store up so much power that an explosion of force follows the slightest irritation, or to that excessive irritability of cell action (irritable weakness) which goes before degeneration as the result of overuse, the cells acting with sudden and delirious violence. Irritability of the cortical centers shows itself by such intense ideas being engendered by any reference to sexual matters that an emotion is created, and the inhibitory power over the spinal center is weakened and it is allowed to discharge itself. A case of this kind is now under the care of Dr. F. J. Magilligan. The patient is a young woman in whom the sight of a man produces an orgasm.

Irritability of the spinal center shows itself by such intense feelings being engendered in the genitals by any exciting cause that the orgasm occurs almost as soon as the erection has taken place. In a large number of cases this condition is a reflex one, due to local congestion of the genital organs. This and spinal exhaustion form the two most common neurotic causes of impotence in the male.

Sexual perversion may arise from three causes—from want of opportunity for normal gratification; in those cases in which sexual excess has exhausted the ganglionic centers, but the pervers find that by stimulating them in some unusual way he regains the lost pleasure; and it forms one of the forms of insanity. Both of the latter cases are due to an abnormal grouping of the nerve cells. In the second set it is due to certain groups becoming exhausted before the others, thus breaking up the normal paths of thought, while in the last this is inherited.

Perverts may be further divided into two classes: in one they retain the power of deriving sexual pleasure in the ordinary way, and in the other this is lost.

Masturbation is the most common and, as a rule, does not much harm beyond the moral effect which is produced by doing that which we believe to be wrong. Paget lays down the law "that masturbation does neither more nor less harm than sexual intercourse practiced with the same frequency and under the same conditions of general health, age, and circumstances." Gray: "I have never seen a case of any disease which has directly been caused in this manner." Dana: "Sexual excesses are usually the result rather than the cause of nervous disorders."

Masturbation is, however, for obvious reasons, more apt to be carried to excess than normal intercourse. It is often one of the evidences of the irritable weakness of the nervous system in the insane and may exist as a true psychosis.

Ten years ago a divorce was granted in this city on the ground that the husband had for over two years been in the habit, after retiring, of masturbating without once making any attempt at natural connection. Masturbation, if it is not the cause, is certainly an early and prominent symptom in one form of insanity. In boys it shows itself in an excessively hypochondriacal and egotistical condition. They become vain, selfish, and deceitful, without natural affection, and suspicious, often with delusions of persecution. In later life they are apt to be shy of women, but often fall in love, the thoughts of which lead to unnatural gratification. If they do marry, it usually ends in suicide or divorce. They may remain in this condition, or become actually insane. Their vanity increases and becomes offensive. They lose all moral feelings, and yet express exalted sentiments and superiority to all men. Visual and aural hallucinations are common, and with these they may have strange bodily sensations, which they ascribe to electricity or hypnotism. They may fall into a pseudo-trance, ecstasy, or catalepsy, often with visions of a religious character. In these cases suicidal and homicidal impulses are not uncommon. I had a case of this kind under observation in the Kings County Hospital.

J. Q., aged twenty-six years, single. Mother now in an insane ward. Addicted to masturbation. Present condition of one month's duration. Lies in bed with eyes shut. Moves no muscle except eyelids, which are in constant tremor. Apparently unconscious. Sometimes upon placing the limbs in any position they will remain so, especially when he has a number of observers. Eyeballs rolled up. Pupils dilated. Gives no evidences of cutaneous sensation.

In women it first shows itself in loss of affection and interest in ordinary occupations. They are capricious, avoid society, and may have hallucinations that their clothes are soiled, infested with insects, or that persons say indecent things to them, or have assaulted them, or that they have had or are going to have a baby; and they will often display the most diabolical cunning in supporting these charges. With this there may be hysterical paroxysms.

Sodomy is the unnatural connection of a man with a man, or unnaturally with a woman, or a man or woman with an animal. The male sodomist who acts the part of

a female is a true sexual pervert, having the gestures and thoughts of a woman. With these may be classed those beings of both sexes who derive sensuous pleasure by bringing their mouths in contact with the genital organs of the opposite or same sex. This last practice seems to produce the most disastrous results of all forms of sexual excess upon the male operated upon, often ending in general paresis. Anthropophagy is that form of sexual perversion where the pleasure is derived by mutilation or cannibalism. Jack the Ripper was probably an example of this class.

Sergeant Bertrand used to dig up bodies, disembowel them, and then masturbate; later he practiced intercourse with the female ones. Homosexuality is the violent passion of a person for one of the same sex. This, in a mild form, is not uncommon, especially among women, and, as an insanity, it was well marked in the Freda Ward murder case.

Sexual hermaphroditism or metamorphosis is where the patient has the feelings, tastes, thoughts, or manners of the opposite sex. Lord Cornbury, one of the royal governors of New York, was a notorious example of this class.

Mosochismus is where one sex derives sensuous thoughts or orgasms upon being dominated over by the other; and sodimus is where the pleasure is derived upon inflicting pain upon the other.

Erotic fetishism is where the orgasm is excited by some article belonging to the opposite sex—as by cutting off the hair, or throwing ink or vitriol on the clothing. With this might be classed voodooism, where the naked buck stands with an erect penis, decorated with ribbons, which is kissed by the devotees.

Most of the cases of sexual perversion which come under our care belong to the second class and the subjects are truly insane. Their inherited or acquired ideas are the result of destruction and anomalous association of the cells of the cortical center. This may remain confined to this part, or spread to other portions and mania result.

With these cases of sexual perversion may be classed those women in whom such intensely modest ideas have been acquired by education that the sexual act not only gives no pleasure, but actually gives rise to feelings of disgust.

Treatment.—It is, of course, of the first importance to remove, as far as possible, any local disorder of the genitals.

Treatment is, of course, of very little value in the congenital cases, but it should be tried if marriage has taken place. The use of such drugs as act as stimulants to the ganglionic cells—such as phosphorus, strychnine, quinine, sodium salicylate, and arsenic—is indicated.

The galvanic and faradaic currents should be tried, the positive pole being placed over the dorso-lumbar spine, and the negative on the inner side of the thigh and perineum, or we may pass the positive pole into the rectum.

Exhaustion of the sexual centers calls for the same medicinal and electrical treatment as in the congenital cases, but with this we should try and give the sexual system the most perfect rest by avoiding any cause which tends to ex-

cite it, and also anything which produces mental or physical fatigue.

Gentle, regular exercise, bathing, and other hygienic measures should not be omitted, and with these a diet rich in nitrogen, with which cod-liver oil may be combined. Irritability of the sexual centers, when due to engorgement, calls for some means of discharging the accumulated force, and this should be done at regular intervals.

Those cases in which it is due to abuse of the sexual functions require the most absolute rest. We should also remove any medicinal or dietetic cause which tends to stimulate the cells.

The diet should be, as far as possible, a farinaceous one. Coffee, alcohol, and spices should be prohibited. Such drugs as the bromides, camphor, and lupulin should be given freely, and the same hygienic measures should be employed. In both sets of cases, if there is feeble heart action and vaso-motor paresis, ergot and digitalis are of value.

Sexual perversion calls for the use of every means which will tend to break up the morbid habits of thought and restore them to their normal channels. We should try and keep the patient continually employed in some healthy physical or mental exercise. Hypnotism has proved of value in some cases, but, as a rule, the prognosis is bad.

339 LAFAYETTE AVENUE.

PROPHYLAXIS AND TREATMENT OF DIPHtheria.*

By BEVERLEY ROBINSON, M. D.

(A) *Prophylaxis*.—At our last meeting, after the debate which followed the reading of my paper on Membranous Sore Throat, it was resolved that a thorough discussion should take place at this meeting in regard to the best means to adopt in order to prevent the extension of diphtheria, especially in towns and cities. This, as we all know, is a most important and also a very difficult problem to settle in anything like a satisfactory and thorough manner. The best that I can hope to do is again to bring the matter before the attention of this association, and in connection therewith to state some well-recognized facts with their seeming practical deductions, and finally lay hold of some general—if not always specific—rules of guidance, which shall be of great use to us as practitioners and to the public, who may lend a willing ear to our affirmations. In this way we shall finally obtain entire municipal control of all those conditions which breed diphtheria.

What I shall have to say will have to do mainly with questions of (1) causation, (2) isolation, (3) disinfection. How is diphtheria caused? For many to-day there is the specific germ of diphtheria, the so-called Klebs-Loeffler bacillus, which is found almost invariably in the exudate of the disease, and is regarded as its distinct, *efficient cause*. It is also true, for those who admit this fact, that this bacillus secretes a poison which penetrates the blood and

the tissues, and through them produces all those secondary effects which are the proofs of systemic infection.* On the other hand, we find evidences of diphtheria taking place in a most virulent form, repeated epidemics occurring, indeed, when no such primary cause was revealed, at least if this primary cause—or diphtheria bacillus—takes its origin, as is now often assumed, from a previous case from which contagion, either directly or indirectly, is carried. Diphtheria has arisen in small villages, in isolated farmhouses, in palatial country dwellings, where no case of this disease had previously been known to exist. We must admit, therefore, that ill-ventilated areas or rooms where dampness and dirt are present, where mold fungi appear upon the walls, that cellars which are wet and contain decaying vegetable or animal matter, are quite sufficient at times to bring this poison into active existence. In the admission of almost all observers, filthy privies and cesspools, broken and clogged drains, water-closets and pipes emitting sewer gas, are also causes for the outbreak of an epidemic which is with difficulty arrested. Whenever the milk or the water supply has in any way become contaminated by sewage or filth from different sources, we again have an etiology of this disease which we are willing to admit. To prevent, therefore, all these causes of disease, to stop a development and spread from them, means, of course, to see that our pipes and drains are intact, that no sewer gas from infected sewers may gain entrance into our houses; that our cellars are kept dry, clean, and well ventilated; that there are no floors near the earth with damp spaces shut in between them, which never receive a free current of air; that our closets and rooms everywhere in our homes are frequently cleaned and ventilated.

Whenever a case of diphtheria actually occurs, what we must immediately do with it is to give the patient the best possible isolation. Before, however, isolation is even attempted let us be sure, as nearly as we can be, that we have to do with a case of diphtheria. For this purpose I claim that it is now the duty of the practitioner in every case of doubtful membranous sore throat to swab the fauces with a sterilized cotton-wrapped stick, and to have the exudate taken from the throat submitted immediately to bacteriological examination. As soon as this is done, and while awaiting the report of this investigation, the patient should be put in a room by himself, as far removed as possible from other members of the household, and preferably on the top floor of the house. Before he is placed in this room everything should be removed from it except articles strictly necessary to the well-being of the patient and his nurse. The air of the room should be changed very often, due regard being always had to outside temperature and to avoidance of draughts. Of course, if there is an open fireplace in the room, it can be ventilated easily and effectively, even though the windows are only partially opened. In the dilution and change of air, we have the

* Remarks in opening a discussion on diphtheria before the American Laryngological Association at its fifteenth annual congress.

* It is now proved that the bacillus of diphtheria is able to penetrate "the circulation and the internal organs" (see Case of Diphtheria of the Heart, *Medical Record*, p. 681, May 20, 1893, also *Johns Hopkins Hospital Bulletin* for April, 1893).

best of all disinfectants for a sick-room with a contagious disease present like diphtheria.

The food required by the patient should be brought to the door of the room and carried in by the nurse. No one should see the patient except the nurse and the physician.

All discharges from the patient's mouth or nose should be received upon cloths, which should be immediately burned. The excreta from the bowels and bladder should be properly disinfected with solution of copperas, bichloride of mercury, or carbolic acid, sufficiently concentrated to be really effective. These rules may all be carried out usually in the dwellings of the rich with very little annoyance, trouble, or expense. They may be made far less rigid or stopped altogether if at the expiration of twenty-four hours the bacteriological researches have proved negative. If, on the contrary, these investigations corroborate the opinion that the case is one of diphtheria, they must be insisted upon during the entire duration of the disease. While the rules above laid down are relatively easy of accomplishment in the houses of the wealthy, can they be rigidly enforced in hotels, boarding houses, and, still worse, among the crowded tenements of our large cities? The answer is that they can not, and that even in our attempt to carry them out we shall cause very great trouble, sorrow, and expense which can not be easily met. It therefore behooves us more urgently still in these latter instances to be sure of our *diagnosis* before effective isolation is seriously attempted.

As I have stated above, I know of only one way to strengthen an uncertain diagnosis, and it is by appealing as soon as possible to the expert bacteriologist and obtaining the results of his research. Meanwhile we must imitate, as far as is practicable, the conduct outlined where the conditions are unusually favorable for complete isolation. Whenever the case assumes the undoubted character of true diphtheria, and is therefore of malignant nature—unless the isolation can be made effective in the home—the patient should be carried to a place where this isolation can be had. In my judgment the only way to accomplish this is to have in different sections of our towns and cities one or more isolating hospitals or pavilions, which should be entirely separate from or exist as annexes of our large city hospitals, where diphtheria patients would be taken and intelligently cared for. This is still one of the long-felt needs of this large city, and indeed of most of our cities and towns. Not, indeed, that it has not been met in a certain measure here with us, as witness our Willard Parker Hospital, located in East Sixteenth Street. But a great many more of a similar kind are required, and not for the very poor only, but for the numbers of people in moderate circumstances living in hotels and boarding houses, who, when taken ill with diphtheria, can not be treated properly, and who are a menace to many well persons in their vicinity, who must remain where they are, unless places were provided where they "could be sent until recovery and disinfection at home have been completed"* (Jacobi). Let us hope that

those who are powerful to work changes in regard to this condition of things will see the great wisdom of so doing. First, let our appeal be made to our legislators, to our boards of health; next, to the charitably disposed, who have already given us orthopaedic hospitals, hospitals for cancer and skin diseases, hospitals for consumptives, homes for the aged, the blind, the deaf and dumb, but none for those stricken down suddenly and most grievously with diphtheria, not to speak of scarlet fever, measles, and small-pox.

In regard to funerals and schools, much might be added. It is evident to all thoughtful persons that funerals of contagious diseases should be strictly private, and not only should the family and friends desire it and carry their wishes into effect, and thus prevent all danger of contagion arising from the presence of afflicted ones in the house or chamber where the deceased is, but the law should assert itself for the public good. The regulations governing funerals of those who have died of diphtheria should be distinct and formal, and a sanitary officer should always be present to see that there is no infringement of them by reason of ignorance or neglect.

In regard to the subject of funerals in New York city, it is only proper to add that the latest edition of the Sanitary Code of the Board of Health provides, in section 204, for the proper regulation of them in cases of contagious disorders. In the latter section it makes it the duty of the undertaker to notify the health department of such cases whenever he encounters them, and forbids him to assist in the public or church funeral of any person who has died of a contagious disease. To what extent the ruling of this section is adhered to, I can not say. I am told, however, by my friend Dr. Alva H. Doty, the present head of the bureau of contagious diseases, that the law is strictly observed in every instance.

In regard to schools, it is clear that no child from a house in which there is a case of diphtheria should be admitted to a school until all danger of contagion is over. The precise time during which such absence should be enforced may be a little doubtful, but it is a safe rule to make that a return to school should not be permitted for one month at least from the time of the inception of the disease. In this connection Jacobi writes (*On the Treatment of Diphtheria in America*, Berlin, 1891, p. 5): "In all large communities the cases of diphtheria are reported immediately for the action of the health board. One of its functions is to protect the schools by communicating with the board of education. The children of a family, or those living on the same floor, where a case of diphtheria has broken out, are kept away from the schools until all danger has been averted. The schools have often been closed when an epidemic made its appearance and threatened to prove dangerous." In the light of present knowledge, however, a physician can not conscientiously give a certificate such as school boards generally exact without a bacteriological examination. "The only safe way is for

* In the debate upon Dr. H. M. Biggs's paper before the New York Academy of Medicine, May 18, 1893, entitled *The Organization and*

Equipment of the Division of Disinfection, New York Health Department, and the Method of Work, this matter was considered and its importance emphasized by Dr. J. D. Bryant, Dr. A. Jacobi, and Dr. Beverley Robinson.

school boards to insist in every case upon the applicant for readmission bringing a certificate from the local health authorities that the requirements of the law have been fulfilled, and that it is safe to return to school. Competent health officers should be appointed not only to supervise isolation and disinfection, but also to make or obtain bacteriological examinations when required, inspect schools in time of epidemic, and grant certificates for the readmission of convalescent scholars." (*System of Practical Therapeutics*, Hare, vol. ii, p. 517.)

Section 169 of the Sanitary Code of New York city, however, is the only one which refers to the matter of protection of schools against the invasion of contagious diseases. Moreover, it does so in very general terms and not in such a way as to govern precisely the action of parents and teachers in this important matter. I would therefore suggest that a section be added which will be at once clear and comprehensive, and thus commend itself to the intelligence and conscience of every citizen. This additional section is scientifically supported by the observations of Roux and Yersin, that the bacillus of diphtheria may be found in the pharynx of persons that have suffered from the disease as long as five weeks after the disappearance of the membrane. As a result of this observation, confirmed by the investigation of other authorities, the conclusion seems warranted that most cases of diphtheria, when dismissed from treatment, still possess the capability of transmitting the disease. "While the likelihood of spreading diphtheria after convalescence from the disease is not great, the practical lesson taught is that the greatest care should be exercised during this period; that the cases be not permitted to mingle too soon with other persons; and that for a long time after the disappearance of the membrane and of all the symptoms of the disease, the patient be instructed to continue the employment of antiseptic gargles." (*Medical News*, December 3, 1892, p. 642.)

During the entire period that diphtheria exists in a dwelling and until the whole of it, or the infected rooms of the house, have been thoroughly disinfected, the people living there should be carefully watched. How many cases of diphtheria are carried by children from such a house to others with whom they play daily or into whose houses they are allowed to enter! How many tailors, dressmakers, washerwomen, scrubwomen from such houses are allowed to send their infected clothing or go themselves to other houses where contagious disease has not entered previously and bring it with them in all its virulence! Should there not be proper and legal control of all these people, so that by a judicious system of enforced isolation they would be prevented from carrying disease and death among many who may become victims of their conduct? As to the physicians themselves, I would make it obligatory upon the physician who attends the case to pull a blouse and overalls over his coat and trousers on every occasion before he entered the room of the patient. These garments should be left at the door of the room and placed in a bag properly disinfected from time to time during the course of the disease; or, indeed, fresh clothing of this kind should be provided for the physician, at every visit,

and when once used should be thrown into a boiling disinfectant solution. The blouse might have a hood which should go over the physician's head as an additional safeguard to others. Another suggestion, perhaps even better, is that the physician in attendance wear an antiseptic gown, also with a hood, reaching to his ankles, somewhat after the pattern of those now worn in some of our surgical clinics. These gowns are made of bleached drilling or pure linen, and usually loosely fitting, so that they can be put on or taken off easily. This idea would appear to have been carried out already in a practical way in the new isolating ward "for doubtfuls" at the Trousseau Hospital, Paris, France, which has proved a great success. "At the usual entrance of the hospital is a vestibule for blouses, which are invariably worn by all who participate in the visit, and are dropped upon the floor of another small room before leaving the building." (*Boston Medical and Surgical Journal*, April 27, 1893, p. 412.)

It is also now the custom to wear gowns in the diphtheria wards at the Willard Parker Hospital in New York city. The doctor should wash his face and hands in a mild disinfecting solution, preferably of boric or carbolic acid, whenever he leaves the sick-room. All these precautions seem useful and indeed imperative. The only objection to their being fully carried out is the effect which they might have on the community in one particular. They would make people, at first, even more timorous than they now are in regard to the transport of contagious disorders. On the other hand, in the course of time, and indeed rapidly, would not these fears be greatly lessened owing to a feeling of far greater security in regard to themselves and those they love? Every one would surely understand that all judicious and necessary precautions had been taken to limit the risks of contagion, and soon, as virulent disease like diphtheria became less frequent, each person would cease to dread it so much, merely because he would rarely have occasion to hear about it at all.

The question of disinfection may now properly claim our attention for a little while. As to disinfection of the sick-room during the time the patient is there, it may well be asked if it is desirable to attempt it, and to what extent. I presume it can be safely answered that anything like complete, satisfactory disinfection is wholly impossible without doing the patient positive great injury, and rendering the room unbearable also for the nurse in attendance. I have no objection to, and indeed should rather indorse, the employment of certain mild disinfecting vapors, which possibly make the diphtheritic germs less active, so far as the patient himself is concerned, and render it less probable that they will do harm to others, if they are carried upon the person of the physician, or in some article of clothing, furniture, bedding, crockery, etc., which has been taken from the room prior to the cure of the patient, or the complete disinfection of all his surroundings. Of course the use of such a disinfectant should not, in any sense, interfere with the immersion in boiling water with carbonate of sodium (Na_2CO_3) of all such articles as can be thus immersed, without injury to them, prior to their being removed from the room. Of the disinfecting agents to be thus usefully

employed, I have no hesitancy in recommending those, in the first place, which can be volatilized readily, and which will thus be able to penetrate every nook and corner of the room, and, in addition, are likely to be useful to the patient when directly inhaled by him, and be brought in contact with diseased surfaces. Further, such agents need not be too unpleasant for the nurse and physician, and may perhaps make them more impervious to contracting diphtheria themselves, and less liable to aid, or cause, its spread outside the sick-room. The more volatile agents, which are frequently placed in saucers around the sick-room, sprinkled over the bed-linen, hung in saturated cloths on either side of the door opening into the hall, or into an adjoining room, although probably unobjectionable, have far less real utility in my judgment. In this list we may place such well-known agents as chloride of lime or permanganate of potassium in solution. Among the volatile agents which seem most satisfactory, and which have, according to some good observers, given valuable results, we may properly include substances like eucalyptus, turpentine, carbolic acid, creasote, and tar. Either one of these agents may be added to a can containing boiling water, and this water may be kept simmering most of the time near the bed of the patient. These agents should not generally be employed in strong enough proportions to occasion any additional local irritation of the respiratory tract. They should simply be added to the water in sufficient quantity to correct at the time the evident catarrhal element which is often so prominent a feature in the rise and development of very many cases of diphtheria. Sometimes one of the agents may be used alone, sometimes various agents may be combined in a similar or different proportion, and the combined drugs may be added to the steaming water. Dr. J. Lewis Smith has found a combination of the following kind to be very useful in his own practice and that of others, and cordially recommends it to those physicians who have charge of cases of diphtheria. It consists of an ounce each of oil of eucalyptus and carbolic acid,* and eight ounces of turpentine. Of this mixture two tablespoonfuls are added to the water contained in a wide pan whose contents are about one quart. In stronger proportions of carbolic acid and eucalyptus this vapor has proved irritating and offensive to some patients. If such a vapor as this is really useful, I can readily believe that it would be well to adopt it for the complete disinfection of many places in which such remedies should, from time to time, be employed, even though there be not invariably the confirmed proof that a true case of diphtheria has been present at the spot. In such category I would include all public places where large numbers of people congregate, or are continually remaining for a while, and then going elsewhere. All schoolrooms, public halls, theaters and other places of amusement, public vehicles, cars, and perhaps churches, should be subjected, at times, to this kind of

local disinfection. Are such vapors more, or less, useful than the well-known sulphur fumigations, which are always resorted to in our city disinfections after the patient has completely convalesced? * I am not authorized to say, and I am not conversant with any experiments which demonstrate clearly their usefulness or their practical inutility. What I do know is this—and this was referred to last year by me at our regular annual meeting in Boston—that sulphur fumigations as carried out by our health authorities are frequently ineffective and highly objectionable. I have alluded already in my previous paper to many of these objections. I would again refer to one which appears to me very important, and which has not, I believe, been often mentioned, and it is that the active member of the disinfecting apparatus is never thoroughly disinfected himself; and it seems to me that he must necessarily be the direct carrier of many more infective germs than he gets rid of by burning a few pounds of sulphur in a closed room. It is evident that this person can not remain in the room long enough to be properly disinfected, even presuming that sulphur vapors would disinfect the outer man. It is certain that this agent, representative at the health board, can not take even a whiff of sulphurous vapor without occasioning himself harassing cough and sensations of suffocation. The vapor referred to above, equally disinfecting with that of sulphur, doubtless can be inhaled, for a while at least, in tolerably concentrated form without causing positive injury, and for this reason alone is preferable; and if the man sent around to different houses by the health authorities would surround himself for a short time even with such vapors, he would probably become less dangerous as a direct carrier of infective disease. A point that can not be too strongly insisted upon in every way, not merely for the patient himself, but for the nurse, the physician, and indeed all persons who in any way have been exposed to the contagion of diphtheria, is the frequent use of mildly detergent and antiseptic gargles, such as those of carbolic acid with borax and water, or of thymol, menthol, wintergreen, combined with more or less saturated solutions of boric acid; or of very mild solutions (1 to 10,000) of bichloride of mercury. By these means I am confident the limitation to the spread of diphtheria will be surely effected. Nothing, we must admit, is more clearly and definitely established to-day than the fact that frequent local disinfection of the mouth, fauces, and pharynx even with very mild agents of this order is most important in diminishing the local extension of the diphtheria exudate, and in this manner lessening the deleterious general effects of the poison secreted by the bacillus, which becomes so rapidly absorbed, and extends throughout the organism in every part.

Again, it is well in time of epidemic to be particularly careful in regard to the management of all throat ailments, even slight in character, and particularly among young

* Instead of carbolic acid, I would prefer creasote in this formula, as being less liable to cause injurious or poisonous symptoms from continuous absorption through inhalation. Indeed, it may be prudent for various reasons to interrupt the inhalations occasionally.

* It has been shown latterly that fumigations with burning sulphur ($=SO_2$) must be rendered *extremely moist* in order to be at all effective, otherwise, they are relatively inert. Biggs (H. M.) before the New York Academy of Medicine, May 18, 1893.

children. I would strongly advise, under these circumstances, frequent gargling with one of the combinations mentioned above, and as additional security I believe a throat inspection should be made daily of all scholars in our public schools, of all children in our homes, by some one competent to discover the first symptoms of local infection with diphtheria. Of course, this obligation becomes still more urgent whenever a child or adult, no matter where found or in what capacity, complains of symptoms of general malaise, allied or not with local symptoms or signs of implication of the throat in acute disease.*

(B) *Treatment of Diphtheria.*—Despite the advances made during the past few years in our knowledge of the pathogeny of diphtheria, as is shown especially in bacteriological investigations of this disease, the treatment of it is still uncertain and unsatisfactory. The really bad, malignant cases frequently progress inevitably to a fatal termination, and in some of them it is doubtful if any treatment thus far tried will arrest their march for a while, or ultimately cure them. Such appears to be the testimony of some excellent observers of wide experience. These fatal cases doubtless become so by reason of the toxic character of the epidemic, and the extreme susceptibility of some patients to the virulent poison of the disease. It is generally admitted, however, that those patients continue to react most favorably who are actively and judiciously treated from the inception of the disease. The mode of treatment seems to vary considerably with different observers. There is, however, a tolerably large and increasing number of eminent practitioners who evidently consider proper local treatment of the highest importance. Of these, many use drugs internally with the conviction of being helpful to the patients.

Among them I would especially cite Jacobi, who thus speaks of the use of the bichloride of mercury when it is given internally: "That its beneficial effect is not at all limited to the cases of laryngeal stenosis, but also those of sepsis. Indeed, in a great many such cases it has been administered and found effective" (*loc. cit.*, p. 17). On the other hand, Osler writes (*Practice of Medicine*, p. 109) that "we are still without a remedy capable of combating in any way the effects of the poisonous toxalbumins." I can not say that I have seen from the bichloride of mercury "the specially good effects which many writers describe." The latest report, moreover, of one of the large German hospitals is to the effect that no internal treatment was employed, and the results obtained with severe cases of diphtheria have been quite favorable as compared with numerous antecedent or contemporaneous results accomplished elsewhere. The report just referred to is that of the Friedrichshain Hospital in Berlin, where it is stated that "during the last two years no drug treatment was instituted," and yet there were sixty-four per cent. cures (*Journal of Laryngology*, March, 1893, p.

124). This experience is also corroborated by that at the Willard Parker Hospital, where, according to Dr. William H. Park (*Medical Record*, July 30, 1892, p. 117) "the only constitutional treatment is to give alcoholic stimulants throughout the course of the disease to those showing any tendency to heart failure." The great difficulty in obtaining the best effects of local treatment is due to our inability to reach directly all the parts involved with topical applications. Ordinarily it is believed that these applications should be of distinctively antiseptic nature. In regard to the particular drug employed, the strength, manner, and frequency of its use, there are great differences of opinion. Of course, the manner in which treatment is conducted must differ somewhat with adults and children, the latter being less amenable to reason and less willing, therefore, to submit quietly to the necessary manipulations for the cure of the disease. Most observers are united in the belief that our main efforts should be directed toward destroying or lessening the vitality of the bacilli, diminishing the local spread of the disease, neutralizing the toxic results of absorption of the poisons produced by the bacilli, and support of the patient's strength with food and alcoholic stimulants. Inasmuch as the majority of cases of diphtheria occur among children, we must first consider how such cases may best be treated. This will depend upon whether the disease affects the nose, the pharynx, the larynx, or all these organs. If it attacks the pharynx, and as soon as we have the first local evidence of this implantation, mild cleansing, disinfectant solutions should frequently be employed. Depending upon the age of the child and its degree of weakness or strength, the throat must be treated with sprays, with irrigation, or with gargles. Sometimes one, sometimes the other method is most successful, according to the age and willingness of the little patient. In this connection, I wish to emphasize the fact that in my experience it is more useful and satisfactory to disinfect and cleanse the throat by means of sprays, employed not directly through the mouth but indirectly through the nose. In this manner nearly every portion of the diseased membrane is brought into more complete contact with the medicated solution than in any other way, and with less distress and fatigue to the sick child. Whenever the spray fills the nasal passages, it will almost inevitably, in the large number of instances, reach almost the entire naso-pharynx, the middle pharynx, and portions at least of the fauces and tonsils. Through efforts of gagging or choking by the patient, the latter parts are surely cleansed and disinfected. Nasal sprays, in my judgment, should be rather coarse, never very strong, and be repeated every hour or two. The frequency of their use should depend somewhat upon the malignancy of the case, the thoroughness with which they are employed, and the time of day or night. In general, I am glad to say that I am in accord, in this opinion, with Dr. C. A. Siegfried—who writes: "In the very young, sprays can be introduced through the nostrils to the back of the throat" (*Medical Record*, November 26, 1892)—and the treatment of the Willard Parker Hospital, where "all patients have their nostrils syringed with a bichloride solution." Dr. A. Jacobi also

* In view of the results of Feer's study (*Medical News*, May 20, 1893, p. 552) it would appear evident that "virulent diphtheria bacilli may be found upon the tonsils in the total absence of deposit." The practical outcome of this observation "leads to the treatment of doubtful cases in times of epidemic."

states, with his very large experience to guide him, as follows: "Gentle nasal injections reach the important part of the pharynx better than injections in the oral cavity." (*On the Treatment of Diphtheria in America*, p. 11.) "Nasal injections must be made early, frequently, and persistently." In speaking of nasal and naso-pharyngeal diphtheria infection, Dr. Jacobi affirms emphatically that "nasal injections alone are beneficial, and sometimes so to a remarkable degree" (p. 13). Immediately after the use of the spray a strong disinfecting solution should be applied directly to the diphtheritic patches in the throat by means of a swab or brush. The sprays for the nose must be preferably made from mild solutions of carbolic acid with lime water, borax, or bicarbonate of sodium, or else from very dilute solutions of bichloride of mercury. The solutions of carbolic acid should not be stronger than one or two per cent.; those of mercury, one to 4,000, 8,000, or 10,000.

In this connection I would mention that the *résumé* of the collective investigation of the *Therapeutic Gazette* (1883) is not favorable to the use of carbolic acid. It is regarded as a useless and positively harmful application. Jacobi seems to support this view, and despite the fact cited by him that Prudden (*Am. Jour. of the Med. Sci.*, 1881) found that a one-sixth-per-cent. solution suffices to stop the emigration of leucocytes (*loc. cit.*, p. 10).

From time to time, or about once every four hours, it is wise to give the fauces, tonsils, and pharynx a thorough, direct cleansing with this same spray, or by means of a syringe. The local applications with a brush or swab to the back of the throat should be made with a solution of bichloride of mercury (1 to 500, or even 1 to 250). During these necessary manipulations the child should remain in bed or be held on the lap of the nurse and wrapped in a blanket. Dr. Billington thus describes how nasal syringing can best be accomplished: "The assistance of two persons is required. The child is seated across the lap of one of these persons, who secures his hands with one of her own, and with the other holds the basin to receive the discharge. The other person stands behind the child, takes his head between the palms of her hands, and, leaning forward, holds it firmly against her breast. A third person, who should when possible be a physician, can then easily make the injection into the child's nostrils without the danger of injury to them by its sudden movements" (*Diphtheria and Croup*, p. 225). To show how opposed is the experience of competent observers, I would cite Jacobi's judgment, which is that "it is acknowledged as a positive rule among all good practitioners that no child must be taken out of bed for the purpose of injections, that the preparations for the procedure must be made out of sight, and quickly but gently, in a recumbent or semirecumbent posture" (p. 12). Subsequent to the cleansing and swabbing, the child should be allowed to rest during a half-hour or an hour. Then a dose of the tincture of the sesquichloride of iron in glycerin and water, or a tablet of bichloride of mercury in solution in water or milk, should be given, followed by liquid food and alcoholic stimulant. The amount of the tincture of iron given should be from

one to two drops for every year of the child's age; that of mercury in tablet form, from one one-hundredth of a grain to one fiftieth of a grain. The best old brandy, in amount proportionate to the age and condition of asthenia, should be given in milk, alternated occasionally with beef juice or concentrated broths of mutton or chicken. Meanwhile, of course, the antiseptic vapors (referred to under prophylaxis) of turpentine, carbolic acid, and oil of eucalyptus should be kept in use more or less constantly. They must also be directed in such a way from a croup kettle under a hood over the child's head, or a tent around the crib with suitable supports and an opening for ventilation, as to allow the child to inhale the vapors sufficiently to obtain an appreciable medicinal effect in this manner.

I have thus outlined what appears to me the most rational way of treating cases of nasal and pharyngeal diphtheria. It is based upon a judicial estimate of the conditions involved, and with due regard for the knowledge thus far acquired through experimental research and clinical experience. There are many other agents, as we all know, in the nature of caustics, astringents, disinfectants, dyes, solvents, etc., which have been praised by different observers for their curative action in diphtheria. Among them all, none seems to me to merit confidence as much as those already mentioned, especially when they are employed after the manner I have indicated. I find, moreover, that a larger number of practitioners laud their use than they do other agents of a similar or different order. Personally I have had good reason to believe that freshly powdered cubeb has a very marked action in changing favorably the character of the membranous deposit, and in lessening the accompanying catarrhal inflammation of the fauces, which always is allied with the evident diphtheritic manifestations.* I have become convinced, through personal observations and experience, that the agents employed by some practitioners with considerable faith can not be relied upon as much as those which I have selected and habitually use.

To make applications more frequently to the nasal passages or to the throat than I have advised is unnecessary and often injurious. They frighten and exhaust the child too much. They do not allow it to take and retain sufficient nutriment. If the solutions are made stronger, they are too irritating to be frequently repeated, and perhaps render the mucous membrane of the parts affected more prone to become involved by the encroachment of the disease than they otherwise would be. I have become satisfied latterly that the failure oftentimes to cleanse the nose and naso-pharynx efficiently is one reason why an otherwise good method of treatment is not oftener followed by the amelioration or recovery of the patient. The cleansing of the nasal passage is carried out whenever the presence of diphtheritic membrane in this organ is assured. In cases, however, in which this membrane is not apparent it is too often neglected. It is my belief that absorption of many poisonous products is thus frequently permitted when it might be in part prevented. I am persuaded that many cases

* Even though cubeb has been shown by Dr. W. H. Park to be innocuous to the diphtheria bacillus, it may have important action in helping destroy its poisonous product.

become much more serious through the omission referred to. Is it not true that absorption from the nasal passages takes place more readily than from the fauces? Do not the most serious cases usually show extension, sooner or later, of the diphtheritic process to these passages? Why not, therefore, avoid or prevent this grave development, if possible, by rational means? In regard to the frequency of local applications I would again urge very strongly *not* to employ them more frequently than I have advised. Meddlesome or too much interference is ultimately injurious in diphtheria, and mainly because it exhausts vitality and prevents essential recuperation by means of rest, food, and stimulants. Applications of undue strength frequently made to the nasal passages occasion pain and irritation, which increase notably the distress of the patient with no compensating return, and make the membrane, by possible abrasions, more susceptible to the virulence of the disease. Whenever the symptoms point unfortunately toward the involvement of the larynx, we should rely far less upon the utility of disinfecting sprays than in nasal or pharyngeal diphtheria, inasmuch as they penetrate very little or at all within this organ. Antiseptic vapors, the internal use of the medicines which have a favorable constitutional effect, are here more to be trusted. In the event of considerable laryngeal obstruction, we must make use of vomiting agents—such as turpeth mineral, alum, ipecac—if the child's strength permits, and follow their use with active stimulation. Occasionally false membranes from the larynx are thrown off by this means, and great temporary relief is obtained. At times no remedial effect is produced, and the child is only weakened and distressed to no purpose, for the laryngeal obstruction after their use is quite as great as previously. Under these circumstances we must look to intubation or tracheotomy as our sole remaining means of help.

I have now almost reached the end of my paper. Not that there is not a great deal more that could be said—not that there is not much of the very highest importance to which I have not even referred. But I feel I have taken up sufficient time with my own remarks and opinions, and I desire to hear from others. I would like our discussion to be widely read, widely reported. It is too important in its many aspects of practical and daily moment to all of us to be ignored or laid aside. I for one would be glad to have our laryngological association have the honor and great satisfaction of indicating the road to reforms which must surely come in time, but need to come speedily and for the great advantage of very many people. In order to show how important isolation and disinfection may become in reducing the number of cases of diphtheria and the number of deaths therefrom, I beg leave to make the following citation: "At a meeting of the Michigan Medical Society the secretary demonstrated in a tabulated statement, accompanied with a graphic chart, important facts in the various outbreaks reported by local health officers during the year 1886. In a hundred and two outbreaks in which there was neglect of one or both of these measures the average number of cases to the outbreak was a little over sixteen and the average number of deaths 3.23; while in a hun-

dred and sixteen outbreaks in which both were enforced the average number of cases was 2.86, and that of deaths 0.66. In other words, these simple precautions reduced the number of cases occurring during the year by 1,545 and the number of deaths by 298."*

In conclusion, I can not do better than to take textually from the last published article of Dr. William H. Park, than whom no one deserves more commendation for his admirable scientific work of great and living interest to almost every one. Dr. Park writes (*Medical Record*, February 11, 1893; reprint, page 23): "The making of a true diagnosis in every case is not of scientific interest only, but of great practical importance. Care for the public health requires that every case of possible diphtheria be properly isolated and treated as diphtheria until all doubt is removed. Regard for the patient demands that no suspicious case that is not diphtheria be regarded and treated as such any longer than the fourteen hours absolutely necessary for making the diagnosis. In doubtful cases, therefore, it is the duty of physicians to obtain a diagnosis by the use of cultures. A correct diagnosis will also be a satisfaction to them, and will be a help in prognosis and treatment, and of great value in the diagnosing of future cases. The efficiency, simplicity, and cheapness of the methods for making an early diagnosis in doubtful cases would seem to render its employment by health authorities among the poorer classes advisable."

THE TECHNIQUE OF THIERSCH'S SKIN GRAFTING.

By C. L. GIBSON, M.D.

THE operation of Thiersch's skin grafting has been in vogue so long and has given such favorable results that it could not fail to have been modified. In some communities the local fame of certain modifications have brought to the latter the character of a model. These modifications and their results have been so widely circulated that further description would appear ill timed. As many of the methods, however, have been in the direction of complicating and elaborating the process, the writer ventures to formulate a method which will comply with all the practical details with the use of fewest minutiae and special apparatus. This work is the result of experience in the practice of many surgeons, both in this country and abroad, and of a small but gratifying personal experience.

The technique consists of three stages, each of equal importance. Failure in perfection of technique in any stage will spoil the whole procedure.

Preparatory Stage.—This deals both with the field to be covered with skin and the field which is to supply the necessary skin.

The field to be covered may consist either of a fresh wound or of a granulating surface.

When we have a fresh wound—*e. g.*, as a loss of sub-

* *New York Medical Journal*, May 21, 1887, page 580—quoted by Billington, in his treatise on *Diphtheria and Croup*, page 149.

stance owing to failure of approximation of skin flaps after amputation of the breast—the only preparation necessary is the observance of absolute asepsis in the strictest sense of the word. Hence the hands which touch these parts must be ridden of the presence of any antiseptic solutions by repeated washing in cooled boiled water, towels treated by heat alone, as also instruments (boiling). Where the use of a solution for irrigation or for moistening dressings is indicated, only the physiological salt solution is to be used—*e. g.*,

Chloride of sodium..... 7 parts.
Boiled water..... 1,000 “

Best prepared by boiling the water in the vessel destined to preserve it.

In the case of granulating surfaces, their preparation consists in an antiseptic stage and a second aseptic stage. When feasible, the process should be begun a week prior to the operation. First shave the surrounding skin liberally. Next wash off with plain water all the dirt possible. Leave on the surrounding skin a piece of muslin evenly covered with green soap. Cover the muslin with some non-porous substance, as oiled paper; leave this on twelve hours. The macerating action of the soap is thus intensified, the superficial epidermis with its numerous micro-organisms is loosened. The scrubbing brush is now diligently applied, and by this mechanical removal of the dirt we accomplish one of the most important objects. Equal parts of sulphuric ether and alcohol are used next to wash the parts, followed by a faithful irrigation with 1-to-1,000 bichloride-of-mercury solution. A dressing of gauze, wet with 1-to-5,000 bichloride, is next applied and renewed daily. Two days before the operation soap is again applied for a short time, say an hour, and the whole cleansing process is repeated. After the irrigation with bichloride, however, a stream of physiological salt solution is played over the parts, and the dressing is accomplished with gauze sterilized by heat and soaked in the salt solution. The dressing and irrigation are repeated the next day again with salt solution as before.

The above described steps are to be followed exactly in treating the skin destined to furnish the grafts.

The Operative Stage.—When the parts are not already prepared to receive the grafts they are subjected to a radical treatment which converts them into a fresh wound. The sharp spoon removes every particle of granulating surface till a fresh raw surface is obtained. The blunt edge of some broad surface, such as the solid-bladed right-angled retractor, will be found of time-saving use where the granulations are flabby. The secret of success lies in the apparently brutal but radical use of these instruments. Sloughing, irregular edges must be trimmed off with knife or scissors. Absolute hæmostasis must now be obtained. Where no spurting vessels are present the wound is simply washed with cold salt solution, then sterilized compresses wet in the same solution are applied to the parts and firm pressure maintained by an assistant or by a temporary bandage, which, if dealing with an extremity, must begin at the distal portion of the limb. Meanwhile the cutting of the grafts is begun. The most suitable place is the thigh, and

will always be chosen where possible. The most advantageous surface is the extensor, next the external.

We wish to obtain large and evenly cut grafts. To insure this purpose the skin must be so stretched that the largest possible area falls into a single plane. Two methods have been used extensively in America for this purpose. One is an ingenious machine devised by Dr. Mixer, which fixes the skin and accomplishes the cutting of the grafts, so to speak, automatically. Another process, devised by Dr. McBurney, fixes the skin in a single plane by tension through a many-pronged hook above and below. While acknowledging the ingenuity and efficacy of these methods, the writer is firmly convinced that such apparatus may be dispensed with by caring for the position of the limb. The hip should be extended and the knee flexed for cutting on the extensor surface; for cutting on the external surface slight adduction should be added. A towel is passed around the limb above and below the operative field, and tension on these in opposite directions by an assistant gives us a surface admirably answering all our purposes.

It is generally recommended to cut the grafts with a razor ground flat on one side, such as is used for cutting histological specimens. Very large razors, practically medium-sized microtome knives, have been used by some operators. These large knives are used to cut extra large grafts. The writer is convinced that any peculiar knife or razor is unnecessary, and even has its drawbacks. None of these knives are ever so sharp as a first-class hollow-ground razor as commonly used in America. Moreover, the sharp razor cuts grafts that are but very little smaller than those cut with the microtome knives, and finally enormous grafts do not necessarily indicate ultimate success.

The dressing is removed from the thigh, the skin is irrigated with salt solution.

The grafts are cut from above downward, in strips about two inches wide and as long as five or six inches. Contrary to general observation, the thicker grafts have yielded the most satisfactory results in the writer's hands; but the razor should never be allowed to penetrate into the subcutaneous tissue. The motion should be a seesaw accomplished rather rapidly and as evenly as possible. A little salt solution should be allowed to trickle on the skin in the razor's path. On cutting through the end of the strip, one of two methods may be employed to transfer the graft to the denuded surface. The razor, with the graft uppermost, may simply be laid on the part, the divided surface overlying the razor's edge withdrawn, cautiously spreading out the graft in its retreat, which is smoothed out with tenaculum and forceps. Another method devised by Dr. Abbe adds a little to the time of the operation, but probably secures better adaptation. The grafts are first thrown into a basin of salt solution warmed to 95° to 100° F. They are then floated on to strips of protective tissue, the raw surface uppermost. As the strips of protective tissue are lifted up out of the water the rather frayed edges are straightened out, and with a pair of scissors may be trimmed off on the tissue. The graft is then laid on the denuded surface, pressed into place with the finger, and

the tissue removed, leaving the graft in perfect position. No harm comes from the transfer to the salt solution. Successive strips may be applied alongside of each other very closely, as is necessary owing to subsequent shrinking of the grafts. No rules can be formulated for patterning the disposition of the grafts to the greatest advantage, this process depending for success on the operator's instincts. While close approximation is desired, the grafts should not overlap, as such projections will find no nourishing base and will slough off.

General anaesthesia is necessary generally for the performance of the operation. Where the extent of the surface is so small that local anaesthesia successfully overcomes the pain, the possible injurious effect of the local anæsthetic on the vitality of the grafts must be borne in mind.

The After-treatment.—The grafts should be covered with strips of protective tissue of an average width of an inch and a half applied so that each strip slightly overlaps the other. A well-fitting protection is thus applied. The chief indications of the after-treatment are protection and rest of the grafts with maintenance of moisture. Formerly the grafts received a daily dressing to maintain the moisture. To do away with this objectionable feature, the following procedure has yielded very satisfactory results in the writer's hands. Cover the grafts with a single layer of sterilized crumpled gauze wet in salt solution. Next lay on one or two soft-rubber drainage-tubes of a length slightly greater than that of the proposed dressing. The middle third of these tubes is perforated with a number of small holes. Above them comes a pretty voluminous dressing of gauze similar to the first layer. Then a covering of dry sterilized absorbent cotton. Finally a sheet of protective tissue slightly larger than the dressing. The whole firmly maintained with a gauze bandage. The tubes project beyond the whole; but obliteration of their lumen is secured by surrounding them with a temporary ligature, clamp, or other suitable device.

The sole local after-treatment for the next five to seven days consists in the daily introduction through the tubes of a sufficient amount of salt solution to keep the dressing wet. At the expiration of five to seven days the dressing should be cautiously removed. We have then to expect the following condition: Grafts moderately adherent and of a pinkish hue. Between their surfaces a little film of pultaceous material resulting from separation of shredly non-nourished filaments. On the surface of the grafts often a little of this material which is only the desquamation of the epidermis. Any attempts at cleansing, irrigation, etc., should be very limited and gentle. The grafts are redressed as at the time of the operation, and the same after-treatment continued. At the expiration of another week the second dressing will show us definitely what has been obtained. Non-adherent portions, if present, will be removed; the wet dressing replaced by the use of indifferent ointments, as further moisture is apt to lead to a boggy, unhealthy condition. Any granulating surfaces, which should rarely occur, are treated on general principles.

For the denuded thigh, a dressing of dry aseptic gauze and cotton is all that is needed. It should remain undis-

turbed for two weeks, and satisfactory cicatrization will follow.

The foregoing description seems rather lengthy, but a large part of it is devoted to the accurate description of the stages of antiseptic and asepis necessary in such operations by any method.

The writer would again call attention to two important features. First, the entire freedom from use of any special instruments and apparatus; secondly, the extreme simplicity of the after-care, this simplicity of itself insuring the necessary rest and protection of the grafts.

46 WEST THIRTY-THIRD STREET.

THE VALUE OF THE OPHTHALMOMETER

IN THE DETERMINATION OF THE AXIS AND
THE AMOUNT OF ASTIGMATISM.

By LOUIS J. LAUTENBACH, M. D., Ph. D.,

PHILADELPHIA,
SURGEON TO THE PENNSYLVANIA EYE AND EAR INFIRMARY;
CHIEF OF THE EYE CLINIC OF THE GERMAN HOSPITAL.

THE results herewith presented are drawn from the study of almost one thousand three hundred eyes with the ordinary tests (the ophthalmoscope, retinoscope, etc.) and the ophthalmometer, and the subsequent determination of the subjective refraction by mydriatics, either atropine or homatropine.

My first experience with the ophthalmometer was with the Helmholtz instrument. This measured the corneal curvatures very accurately, but required quite a long sitting to complete the examination, sixteen readings being necessary for each eye.

It is mainly on this account that it has proved to be a useless instrument in the working office, being, however, of great value for scientific research.

Later (in 1892) I began to use the Javal-Schiötz instrument, and now use it regularly in every case. Since I purchased it I have examined the eyes of over six hundred patients.

I consider the make of the instrument and its mode of use responsible for much of the difference in results of ophthalmometry, or rather, as it should be termed, keratometry.

My instrument is one made by Meyrowitz, of New York. It is solidly constructed with a good metal base, and its head-rest is attached by a metal support directly to the base; there is no vibration and no give to it; the parts are all fixed and firm. I have four sixteen-candle-power incandescent lights attached to the head-rest to illumine the disc.

After the instrument had been constructed and delivered to me I had the arc set in proper position and the prisms overhauled by Mr. Seidel, of Philadelphia. After this was done the results were markedly more accurate than before, as the slightest deviation in the setting of the arc modifies the reading of the axis and the amount of astigmatism.

The instrument is mounted on a firm typewriter stand with an overlapping leaf to give room underneath for the patient's knees as well as to give him a place to rest his arms and hands.

In the barrel of the instrument on the center of the lens I have fastened a square of green paper of five millimetres. This is a most necessary procedure, as by no other method have I been able to fix the patient's eye so well.

Fastened to the head-rest of the instrument I have a pair of straps by means of which I prevent any forward or backward motion of the head.

In order to have the patient's head and neck comfortable when resting in the headpiece, I have a chair which I raise or lower to the proper height.

In taking my readings I turn on the electric current, place the patient in the chair, raise it to the proper height, have him rest his chin on the chin-rest and press his forehead against the upper part of the rest, place his eyes at the proper height and see that they are on a level, tighten the straps just below the occipital protuberance, seeing that he is resting his feet firmly on the floor and his arms on the table; then, the spider's web being in proper position, I cover his left eye with the slide and direct him to look at the square in the barrel.

I then focus the image accurately by raising or lowering the screw, pushing the barrel to the right or left and drawing it to or from my patient. I commence invariably with my indicator pointing to 90° and bring the mires in apposition at this point, the center of the line of apposition being at the cross of the spider's web.

If the central lines are not continuous I revolve to the right or left until they are continuous, and then again bring the mires into apposition. I then note this axis, and also the radius of curvature.

I then turn the indicator just 90° from this, and if the lines are again continuous I note this axis and the amount of overlapping of the mires or their divergence; then again bringing the mires into apposition, I again note the corneal radius.

If the lines are not continuous I revolve to right or left until they are so, and proceed as before indicated. I then examine the left eye in the same way.

Usually the whole procedure—the examination of both eyes—will not take over three minutes, and the results are so accurate that subsequent examinations give absolutely the same results.

I speak of this accuracy as I have noted others who indicate that frequent examinations are necessary. This accuracy and time saving is, I think, the result of the perfect illumination and the fixed and accurate position, as well as the ease and comfort in which the patient is placed.

Occasionally I find a cornea very hazy. In these cases I use a drop of castor oil instilled into the eye, and, closing the lids, rub the eye very gently. Again I find the image becoming hazy while under examination. This is due occasionally to a lack of secretion, but more frequently to an excess. In these cases I direct the patient

to wink two or three times or to close the eye for a few moments and then continue the examination. Occasionally when the arc is vertical or nearly so the image of the white parallelogram is either indistinct or it disappears; this is obviated by directing the patient to open his eye wider, a heavy eyelid being the cause of it.

I am more and more convinced that Burnett's allowance of 0.5 D. as the difference between the astigmatism of the ophthalmometer and the subjective astigmatism is too high. I make an allowance of 0.37 D., subtracting this if the astigmatism is with the rule and adding it if against the rule.

My cases have been so numerous and I have been so busy in many ways that I have not thoroughly analyzed them, but will here give you the results—the practical results:

1. That the ophthalmometer of Javal and Schiötz will determine the axis and amount only of the corneal astigmatism.
2. That it will determine accurately the axis of astigmatism in between eighty and ninety per cent. of the cases.
3. That in about forty-five per cent. of the cases (making the correction of 0.37 D.) it will determine the amount of the astigmatism.

A CASE OF NASAL POLYPUS PROJECTING INTO THE NASO-PHARYNX.

WITH SPECIMENS.*

By SAMUEL JOHNSTON, M. D.,
BALTIMORE.

The patient from whom these specimens were removed was sixty years of age.

She consulted me with a history, briefly, of nasal obstruc-

FIG. 1.—Side view of the polypus.

FIG. 2.—Front view.

* Read before the American Laryngological Association at its fifth annual congress.

tion, difficulty in swallowing, and impaired voice production. For many years previous to the onset of these symptoms she had suffered from catarrh, but had never had epistaxis.

Several reflexes were present, notably asthma, and her distress was indescribable.

Upon anterior rhinoscopy, the right nostril was seen to be occluded at its posterior opening, the left one being pervious.

FIG. 3.—Recurrent growth.

On inspecting the mouth, a tumor of unusual size, grayish in color, non-vascular, and firm to the touch, was observed to protrude between the border of the soft palate and the post-pharyngeal wall.

When vocalization was attempted, the growth disappeared into the naso-pharynx, pushing forward the velum.

After removal with the snare, the growth was found to be of about the size of a pullet's egg, slightly flattened, with a smaller one adjoining, and was seen, upon examination, to have had its attachment by a narrow pedicle to the inferior turbinated bone.

A year later the patient returned with a train of symptoms similar to those presented on the first occasion, though not so pronounced. Examination revealed a mucous polypus hanging freely over the velum, almost touching the base of the tongue. The gross appearances of this growth were quite in contrast to those of the first one.

The tumor measured two inches in length and three quarters of an inch at its thickest part.

Polypi having their origin in the nasal passages and growing posteriorly to the size of these specimens are uncommon in my experience, and I have thought them not unworthy of presenting to the association.

The American Medical Editors will have a meeting and banquet in Washington on the evening of Monday, September 4th, the day preceding the assembling of the Pan-American Medical Congress. Dr. I. N. Love, of the *Medical Mirror*, 3642 Lindell Avenue, St. Louis, has been appointed chairman of the committee of arrangements for the banquet, which fact, says the *Alienist and Neurologist*, gives ample assurance of the success of the latter. It is earnestly hoped that every medical editor of all the Americas will endeavor to be present on the interesting occasion.

THE NEW YORK MEDICAL JOURNAL,

A Weekly Review of Medicine.

Published by
D. APPLETON & Co.

Edited by
FRANK F. FOSTER, M. D.

NEW YORK, SATURDAY, AUGUST 5, 1893.

THE MILK SUPPLY OF CITIES.

THE milk supply of large cities is a subject of supreme importance. Not only is milk an essential element in the diet of adults, but it is the exclusive food of thousands of invalids and young children. Impurity means illness and discomfort to many, and to some actual death. The enormous death rate of children in summer is in large measure directly attributable to changes in the milk which constitutes their food. Much attention has been devoted to the subject by the medical profession for several years. For some time the main object seemed to be to render milk safe by certain processes after it reached the city. Attention was chiefly directed to sterilizing the milk, and a little later to Pasteurizing. Recently the more rational view has been promulgated that the chief attention should be devoted to the management of milk at its source of supply. In every discussion upon the artificial feeding of infants, physicians come back to the fundamental principle that in large cities we are handicapped by the quality of the milk received, and conclude that but little further advancement is to be made until cleaner and purer milk is obtainable. In New York there has unquestionably been a decided improvement in the character of the milk in recent years. The quality, so far as adulteration and constituent parts are concerned, is, on the whole, excellent. For this result we are largely indebted to the board of health. Its supervision over the milk supply is constant and very efficient, but it has reached its limit of power. The chief objection to the milk now received is the large amount of bacteria and organic filth which it contains. Adulterated milk causes indigestion, rickets, and marasmus. Filthy and germ-laden milk causes entero-colitis and speedy death.

It is also true that great improvement has been effected during the last ten years in the management of cows, in the care of the milk at the farms, and in transporting it to the city, but much still remains to be done. Certain vital points have until recently been overlooked. In Boston, under the supervision of Dr. Rotch, milk produced at farms under close medical supervision can be obtained. He has established the most complete and perfect laboratory in the world. Physicians, by simply writing a prescription stating the percentage of fat, casein, and sugar desired for any special case, can have it delivered daily in the form of absolutely pure, clean milk, the exact proportions of the various constituents having been determined with mathematical exactness. Such laboratories will no doubt soon be established in other cities, and will prove of incalculable aid in feeding infants and delicate children. In New York a few milk companies are selling a comparatively clean

milk obtained from farms where close attention is given to the housing and care of the animals and to the transportation of the milk. In most of these a few important points as regards the personal care of the animals and cleanliness in milking have been overlooked.

The most nearly perfect plan for procuring cow's milk designed for clinical purposes which has been carried into practical effect is probably that recently perfected by Dr. Henry L. Coit, of Newark, New Jersey. In describing this plan he refers to the folly of relying upon legal enactments, or even public opinion, to secure clean milk. It can only be obtained from dairies under the supervision of medical men. His plan includes several general requirements, each of which is very essential. It is, first, important that physicians should give their practical support to the movement, which must be conducted by a commission of physicians acting without pay and having no financial interest in the business, who shall endeavor to bring to the city a supply of milk produced under such regulations that purity will be assured. It is also necessary that dairymen possessing honor, financial ability, and dairy facilities should be induced to conduct their dairies in conformity with a code of requirements made by this medical commission and imposed by it in legal form. Such contracts should take into account the location and character of the land: the construction of buildings; the water supply; the health and breed of the stock; the housing, cleaning, and feeding of the cows; the collecting, handling, and cooling of the milk; and its bottling and transportation. Such a plan requires frequent personal inspection, and frequent examinations of the stock by a competent veterinarian. The milk must also be frequently subjected to chemical analysis and bacteriological tests. The question at once arises as to whether owners of dairies can be induced to submit to such regulations. The answer is plain. The milk business, like any other business, is carried on for profit. If dairymen find that it is more profitable to produce clean milk than foul milk, they will produce clean milk. The inducement to the dairyman will lie in the fact that his milk will be known as certified milk, and can be sold at an increased price and in larger quantities. These certificates of purity are to be given at stated intervals, signed by the members of the commission, the chemist, the bacteriologist, and the veterinarian.

Could such a movement be begun in New York, its results would undoubtedly be felt quickly. Bad methods result in part from ignorance and in part from carelessness. A few properly conducted dairies would do much to teach the average dairyman proper methods, while the increase of sales and higher price obtained would stimulate him much more. We understand that a committee of the Pædiatric Section of the Academy of Medicine has this milk question under consideration, and proposes to formulate rules for the guidance of dairymen in the endeavor to procure pure milk. It is a proper and commendable undertaking on the part of that section, which has a most vital interest in the subject. We fear, however, that results will be slight unless it is made apparent to producers that clean milk will pay.

A PRACTICAL COURSE IN HYGIENE FOR HEALTH OFFICERS.

REFERENCE has been made in these columns to the fact that very few of the medical colleges of the United States give instruction in hygiene. The fact that any physician may be called upon to fill an office that will demand of him the most comprehensive knowledge of the ætiology and the prevention of disease does not seem to be a sufficient reason for satisfying the demand that the student should receive thorough and systematic instruction in all that pertains to hygiene before graduation. In fact, recent events in medical circles in New York have been characterized by an implication that, like the poet, the hygienist is born, not made. That a physician is *ipso facto* an hygienist seems to be commonly accepted by the profession and the laity, though the physician himself finds that his official career is beset with errors and difficulties entailed by his lack of familiarity with the necessities of his office.

To give such assistance as was possible and desirable to physicians that had been called to fill the position of health officer, and that found themselves handicapped by reason of inattention to subjects a knowledge of which was of daily necessity, the surgeon general of the Marine-Hospital Service established tentatively during the past winter a school of practical instruction for State, county, and municipal health officers at the hygienic laboratory of that service in Washington.

The course is under the direction of the medical officers of that service on duty in Washington, and consists in instruction in practical bacteriology, with particular reference to the bacteriology of cholera and typhoid fever, the application of the different methods of disinfection, the principles of quarantine administration, the subject of immunity and disease, the examination of air, water, and soil, and such other practical subjects as pertain to a health officer's duties. This course is given without charge to any of the officials above specified, and it has been attended by health officers from Minnesota, Tennessee, and other States. The success that it has met with so far has induced the surgeon general to make it a permanent institution of the service, and he purposes issuing a general circular to health officials setting forth the plan and scope of this practical course in hygiene.

MINOR PARAGRAPHS.

THE ROTUNDA LYING-IN HOSPITAL OF DUBLIN.

A CLINICAL report of this well-known institution, one of the largest of its kind, for the three years 1889-'90, 1890-'91, and 1891-'92, has recently been read before the Irish Academy of Medicine by Dr. Smyly, master of the hospital. During the three years comprised in this report 3,602 women were confined in the hospital, of whom 37 died. In the first year 10 women died of some form of blood poisoning, or about 0.83 per cent., while among the 2,403 women delivered during the two subsequent years there was not a single death from this cause. Twenty-one cases of prolapsed funis took place, with 25 children, 8 of whom died, and there were 17 cases of placenta prævia—an average of 1 in 212. Eleven children were dead, and

one mother was lost by rupture of the uterus. Forty-four cases of accidental hemorrhage occurred, 5 of which proved fatal. The following is the line of treatment which is now adopted in these cases at the hospital: When labor pains are absent, the vagina is washed out with hot antiseptic solution (110° F.), the vagina plugged, and a binder applied. When labor pains set in, the membranes are ruptured and a foot is brought down, or, where practicable, forceps delivery or perforation performed. There are cases, however, which do not admit of any delay, and yet the os is not sufficiently dilated to deliver immediately *per vias naturales*. In such cases Porro's operation is the only method which holds out a hope of saving the mother's life. Post-partum hemorrhage occurred in 48 instances. Plugging the uterus with iodoform gauze was found an efficient substitute for the use of perchloride of iron. There were 107 forceps cases, or an average of 1 in 33.6; 29 of the children were dead. The largest child born weighed eleven pounds ten ounces, and measured twenty-two inches; and the longest umbilical cord measured forty-six inches, and was coiled four times round the neck.

EXPERIMENTS ON THE GENESIS OF EPITHELIAL CANCERS.

At a recent meeting of the French Academy of Sciences Dr. Henry Morau stated that he had been experimenting with regard to the aetiology of epithelial cancers since 1888. The *Medical Week* for July 14th formulates the results of his experiments as follows: 1. White mouse epithelioma is inoculable from one animal to another of the same species. 2. Hereditary influences play a very important part in the development of these tumors. 3. Secondary growths are apt to form in various parts of the body, and the development of these metastatic formations is favored by an injury to the tissues or organs. 4. Gestation produces the same effect as traumatism. 5. Certain toxins are produced in the substance of these tumors that are absorbed into the system and give rise to general cachexia. 6. These tumors apparently lose their virulence by successive transmission through a series of animals of the same species. 7. So long as the skin is unbroken these tumors are apparently free from bacteria. 8. Picric acid seems to exert a favorable influence on these tumors by coagulating the protoplasm of the cells, if injected interstitially.

IODIDE OF STRONTIUM.

In the *Times and Register*, Dr. Waugh reports that he has used this drug in two cases of non-febrile rheumatism. The patients had been treated with sodium salicylate with a fair degree of success, but the symptoms returned immediately upon the discontinuance of the remedy. He then substituted a treatment by means of strontium iodide, beginning with four drachms daily. The dose was reduced to one half as the symptoms receded. The result was gratifying, but, as both patients were residents of damp houses, the recurrence of the disease, at much longer intervals than before, was not prevented. The patients' general health was much better under the strontium treatment than under the use of salicylates.

ULCERATIVE ENDOCARDITIS AND GONORRHOEA.

The *Medical Week* for July 14th states that at a recent meeting of the Berlin Society of Physicians Professor Leyden reported the case of a man, aged twenty-two, who had contracted gonorrhoea, which had been followed by an attack of acute gonorrhoeal rheumatism toward the termination of which aortic incompetence had taken place. At the necropsy the

heart was found to present the appearances of ulcerative endocarditis and the kidneys those of parenchymatous nephritis, and there was a splenic infarct. The occurrence of ulcerative endocarditis in the course of an attack of gonorrhoea admits of two explanations: either the gonorrhoea is directly the cause of the endocarditis or the latter is the consequence of a secondary infection by the organisms of suppuration (staphylococci and streptococci) that become deposited on the endocardium and the valvular segments. In this heart a diplococcus was found in the interior of the cells in the vegetations that was decolorized by Gram's methods and morphologically resembled the gonococcus of Neisser.

THE UNIVERSITY OF PENNSYLVANIA.

It is said that the chair of clinical gynaecology in this institution, formerly held by Dr. William Goodell, has been offered to Dr. Charles B. Penrose. The hospital of the University will presently receive, by vote of the last Legislature, the sum of \$115,000, of which \$15,000 is specially appropriated for the maternity establishment. Other Philadelphia hospitals were liberally remembered at the same time.

ITEMS, ETC.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending August 1, 1893:

DISEASES.	Week ending July 25.		Week ending Aug. 1.	
	Cases.	Deaths.	Cases.	Deaths.
Typhus.....	0	1	0	1
Typhoid fever.....	13	3	24	8
Scarlet fever.....	52	5	38	4
Cerebro-spinal meningitis.....	14	12	9	10
Measles.....	177	9	179	11
Diphtheria.....	99	37	92	27
Small-pox.....	11	1	2	0

The Colorado State Board of Medical Examiners gave notice on the 24th of July that thereafter it would recognize only diplomas from three-year schools as entitling their holders to a license, the courses to be of at least twenty weeks each and given in three separate years, a preliminary examination having been required and instruction having been given in anatomy, chemistry, physiology, pathology, materia medica and therapeutics, obstetrics and gynaecology, surgery, medical jurisprudence, theory and practice of medicine, and hygiene.

The Richmond Academy of Medicine and Surgery.—At the next meeting, on Tuesday evening, the 8th inst., the concluding portion of a discussion on The Influence of Polluted Water and Milk on Typhoid Fever will be opened by Dr. W. S. Gordon.

Change of Address.—Dr. Luther S. Harvey, to No. 32 Adams Avenue West, Detroit.

The Death of Dr. James O'Rorke is reported as having taken place at his home, in West Forty-sixth Street, on Sunday, the 30th ult. The deceased was a graduate of the Jefferson Medical College, of Philadelphia, of the class of 1847, a consulting physician to St. Vincent's Hospital, and a practitioner held in high esteem by his professional brethren and by the community.

The late Dr. James O'Rorke.—At a special meeting of the Medical Board of St. Vincent's Hospital, held on the 1st of August, 1893, to take action on the death of James O'Rorke, M. D., who for nearly forty years had diligently served as attending and consulting physician, the following preamble and resolutions were unanimously adopted:

Whereas, In the death of Dr. James O'Rorke the sick in the hospital, the good Sisters, and the Medical Board have lost a faithful, devoted, and wise adviser, who for more than half the allotted span of

human life had labored unceasingly, tenderly, and skillfully for the relief of thousands of sufferers, many of whom remember with gratitude his kind and gentle ministrations;

Resolved, That the members of the Medical Board signify their deep sorrow at the demise of their honored colleague, for whose integrity, sound judgment, and professional acquirements they have always entertained the greatest respect.

Resolved, That the Medical Board express to the family of the deceased its warmest sympathy in their sad bereavement.

Resolved, That a copy of these resolutions be transmitted to the family of the deceased.

Resolved, That this action of the Medical Board be published in the medical journals.

[Signed.] JOHN A. MCCREERY, M. D.,
Secretary of the Medical Board.

Army Intelligence.—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from July 16 to July 29, 1893:*

WOOD, LEONARD, Captain and Assistant Surgeon, is relieved from duty at Presidio of San Francisco, Cal., and ordered to Fort McPherson, Georgia, for duty.

CRAMPTON, LOTIS W., Captain and Assistant Surgeon, is relieved from duty at Fort Spokane, Washington, and from temporary duty at Headquarters Department of the Colorado, and ordered to Baltimore, Md., as attending surgeon and examiner of recruits, relieving EWING, CHARLES B., Captain and Assistant Surgeon.

GLENNAN, JAMES D., First Lieutenant and Assistant Surgeon, is ordered to report to the President of the Examining Board for examination for promotion.

CLEARY, PETER J. A., Major and Surgeon, is granted leave of absence for four months on surgeon's certificate of disability.

BRADLEY, A. E., First Lieutenant and Assistant Surgeon, is ordered to report to Lieutenant-Colonel Dallas Bache, Deputy Surgeon General, President of Examining Board, at Omaha, Neb., for examination for promotion to the grade of captain.

CLARKE, J. T., First Lieutenant and Assistant Surgeon, will, on the abandonment of Camp Poplar River, Montana, proceed to Fort Sully, South Dakota, for temporary duty, and on return of First Lieutenant Bradley proceed to and take station at Fort Omaha, Nebraska.

DE WITT, CALVIN, Major and Surgeon, is granted leave of absence for one month, to take effect between the 15th and 30th inst. Par. 2, S. O. 78, Headquarters Department of Texas, July 11, 1893.

JOHNSON, RICHARD W., Captain and Assistant Surgeon, will report on or before August 6, 1893, to the commanding officer, Fort McHenry, Maryland, for temporary duty at that post during the absence of EWING, CHARLES B., Captain and Assistant Surgeon.

MAUS, LOUIS M., Major and Surgeon, is granted leave of absence for one month, to take effect when his services can be spared at Fort Wingate, New Mexico.

TEN EYCK, BENJAMIN L., First Lieutenant and Assistant Surgeon, is granted leave of absence for two months, to take effect on or about September 15, 1893, with permission to apply for an extension of one month.

DAVIS, WILLIAM B., Captain and Assistant Surgeon, is relieved from duty at Fort Sam Houston, Texas, and ordered to Fort Brown, Texas, for duty, relieving TORNEY, GEORGE H., Captain and Assistant Surgeon. Captain Torney, upon being relieved by Captain Davis, will proceed to and take station at Philadelphia, Pa., as Attending Surgeon and Examiner of Recruits at that place.

Naval Intelligence.—*Official List of Changes in the Medical Corps of the United States Navy for the two weeks ending July 29, 1893:*

BAILEY, T. B., Passed Assistant Surgeon From Philadelphia Hospital and to the U. S. Steamer Machias.

JONES, W. M., Medical Inspector. From League Island Navy Yard and to wait orders.

COOK, G. H., Medical Inspector. To the Navy Yard, League Island.

DICKSON, S. H., Surgeon. From Marine Barracks and to the Dolphin, temporarily.

RIXEY, P. M., Surgeon. From the Dolphin and granted temporary leave. GATEWOOD, J. D., Passed Assistant Surgeon. Temporary duty at Marine Barracks.

WENTWORTH, A. R., Passed Assistant Surgeon. From the Atlanta and granted leave.

FARWELL, W. G., Surgeon. To temporary duty on the Franklin.

HIBBETT, C. T., Surgeon. From the Franklin and to the Detroit.

BROWNELL, C. W., Assistant Surgeon. Ordered to Receiving-ship St. Louis.

BABIN, H. J., Surgeon. Ordered to temporary duty at Naval Station, Port Royal, S. C.

ALFRED, A. R., Assistant Surgeon. Detached from the Franklin and ordered to the Minnesota.

MOORE, J. M., Assistant Surgeon. Detached from Norfolk Hospital and ordered to the Franklin.

KERSHNER, E., Medical Inspector. Assigned to duty on board the U. S. Steamer New York.

URIG, J. F., Passed Assistant Surgeon. Assigned to duty on board the U. S. Steamer New York.

WILSON, H. D., Assistant Surgeon. Detached from the Minnesota and ordered to the New York.

KIDDER, B. H., Medical Inspector; WELLS, H. M., Medical Director; ANDERSON, FRANK, Surgeon; and BIDDLE, CLEMENT, Passed Assistant Surgeon, granted leave of absence.

Answers to Correspondents:

No. 410.—1. Scrub the lower portion of the abdomen, the mons Veneris, and the external genitalia with soft soap, shave off the pubic hair, and then scrub the parts with ether to remove fatty matter, and then with a solution of bichloride of mercury. Determine the position of the pubic spines and make a vertical incision with a scalpel over the center of the symphysis pubis and down to the ligament. Then introduce a curved probe-pointed bistoury below and behind the symphysis until it can be felt under the pubic arch, and cut from below upward and from within outward until the fibers of the symphysis are cut through. Dust the wound with iodoform or aristol and after delivery dress aseptically. See leading article in the *Journal* for July 17th.

2. Yes. The decomposition would not occur so quickly in new tin basins as to affect the antiseptic property of the solution. The infection you speak of was due to other causes.

Proceedings of Societies.

NEW YORK NEUROLOGICAL SOCIETY.

Meeting of June 6, 1893.

The President, Dr. M. ALLEN STARR, in the Chair.

Convulsive Tic.—Dr. J. F. TERRIBERRY presented a man, aged thirty-nine years, married, a gravel-roofer, whose father had died of senile gangrene and his mother of hemiplegia. He was one of a family of fourteen children. Three brothers had died from the effects of excessive use of alcoholic stimulants; the other members of his family were living and well. The patient's previous health had always been good; until within the past nine years he had used alcoholic stimulants and tobacco excessively; he denies venereal disease; there was no history of rheumatism.

Between eight and nine years ago he had noticed slight twitching of the muscles about the left eye; this had gradually become more marked, extending to the muscles of the cheek, and in a short time all the muscles of the left side of the face had been involved in a spasm. There were intervals of an hour or two between the jerks; his wife stated that they were present during sleep. The trouble was aggravated by talking

and emotional excitement. A careful examination failed to reveal any organic trouble, either central or peripheral, in the course of the seventh nerve that could act as a cause. There had, however, been decided nasal obstruction on the left side, which had been removed by Dr. C. H. Knight. Some errors of vision also had been discovered, which had been corrected by Dr. Adams. The spasm of the facial muscles, however, had in no way been affected by the correction of these defects. The operation of stretching the facial nerve had been advised and had been performed on January 5, 1893. The patient had been etherized and the nerve stretched after the method described by Baum, in which the nerve is exposed by incision behind the ear. A weak faradaic current greatly facilitated the search for the nerve. When it was found it was picked up with a blunt hook and stretched, the force employed being variously estimated at from four to seven pounds. The immediate result of the operation in this case had been, as had been expected, complete paralysis of the muscles of the left side of the face. There had been no effect upon the hearing, the taste, or the palate muscles, showing that the effects of the traction had not been felt centrally. In the latter part of March a gradual return of voluntary control of the facial muscles had been noted, and this had steadily increased. The last electrical examination had been made on the day of the meeting, and the muscular reactions had been found to be good. With the exception of the occipito-frontalis, which was a trifle less active than its fellow on the right side, the face movements were perfect. There had been no return of the spasm since the operation.

The operation of stretching the facial nerve was introduced by Billroth and Nussbaum in 1872. Thus far (including the present one) twenty-three cases had been reported. Temporary facial paralysis had followed the operation in all cases.

Dr. A. E. ADAMS said he had examined the man's eyes a number of times. There had been slight muscular insufficiency and hypermetropia of the right eye. The correction of these ocular defects by means of glasses had produced only a temporary improvement in the spasm of the facial muscles.

THE PRESIDENT referred to the fact that in some of these cases a cessation of the muscular spasm could be produced by pressure upon one of the three branches of the fifth nerve.

A Consideration of the Paræsthetic Neurosis.—Dr. JOSEPH COLLINS read a paper with this title, based on an analysis of forty-three cases. He had endeavored to exclude from these statistics cases of acro-neuroses which, while they presented some of the symptoms of paræsthetic neurosis, had other individual and more pronounced symptoms of their own.

The clinical picture of paræsthetic neurosis was as follows: The sufferers from the affection were in fairly good health; were it not for the paræsthesia, they would not have occasion to consult a physician. The paræsthesia which they complained of were made up of gnawing, boring, and "pins and needles" sensations in the extremities, particularly the upper, involving the fingers, hands, and forearms, often of both sides, but not infrequently of only one. These sensations were not limited to the distribution of any one particular nerve in the extremity, but spread over the entire member with equal intensity. There was rarely any pain in the sense in which that word was ordinarily used. There were no fairly constant objective phenomena. Occasionally the circulation of the extremities was evidently somewhat sluggish. There was absolutely no tenderness on pressure over any of the nerves of the part, and there were no perceptible changes of a trophic or degenerative nature. The affection showed itself intermittently, in paroxysms, and the period of the twenty-four hours when an attack was most likely to occur was from four to six in the morning, the perverted sensation at this time sometimes becoming so severe as to awaken

the patient and put an end to any further rest. Another favorite time was a corresponding hour in the afternoon. The work that the patient was doing seemed to have a very close relationship to the onset of an attack. In some patients it could always be precipitated by sewing, washing, or scrubbing. There was no loss of sensibility or of muscular strength; the patients complained, however, that the strength of their arms was more easily exhausted than formerly. The average age of these patients was just above thirty-nine years. The disease was much more common in women than in men. The most striking factor in the ætiology of the disease was the occupation; of the women, about seventy-five per cent. did either washing, scrubbing, or needlework. Neither heredity nor neuroses (such as hysteria, neurasthenia, etc.) seemed to be associated with this form of hyperæsthesia. No particular disturbance of the digestive functions was noticed. When alcohol was apparently a causative factor of the paræsthesia, Dr. Collins thought it should be classified under the toxic variety. What relationship this form of paræsthesia bore to autotoxemia and the lithæmic constitution was not easily decided. The author doubted if there was any closer relationship between it and the lithæmic diathesis than there was between lithæmia and the development of neurasthenia or some of the vaso-motor neuroses. Gout and rheumatism did not seem to have any causative relationship. Bodily fatigue, overexertion, poor nourishment and ventilation—in fact, anything that lowered the vigor and health of the body—were powerful predisposing factors.

Dr. Collins suggested the following classification of the paræsthetic neurosis, and illustrated each class by giving the history of a typical case that had come under his observation. The classification was founded principally on an ætiological basis: 1. The emotional type. 2. The mental. 3. The neurasthenic. 4. The toxic. 5. Walking numbness (?). 6. The type which might be called an occupation paræsthesia, as it was so often associated with a certain class of occupations. Regarding the treatment of this latter form of paræsthesia, to a consideration of which the paper was mainly confined, there was no specific remedy. Prolonged rest appeared to be the most beneficial agent, particularly when restorative treatment was added. The administration of neurotics and depressants, such as antipyrine, phenacetine, and the like, Dr. Collins considered positively harmful. The use of the faradaic current in the shape of the local bath had proved beneficial in some cases. Spring waters and mineral acids he had not found to be of value. The plan of treatment which was most beneficial was regulation of the diet, particularly by limiting the nitrogenous foodstuffs, a quiet, outdoor life, change of occupation and habits, and the administration of restoratives.

Dr. J. A. BOOTH said that the cases of paræsthetic neurosis that had come under his observation he had been accustomed to group under the headings of neurasthenic, anæmic, lithæmic, and those occurring at the menopause. Among the lithæmic cases he had noticed, contrary to the experience of Dr. Collins, that the condition was often associated with marked digestive disturbances. These patients had been improved and quite a number of them cured by correcting the diet, the use of mineral acids, and the application of the faradaic current by means of the brush. The cases embraced under the various other headings had been treated symptomatically.

Dr. MARY PUTNAM JACOBI said that in the cases narrated by Dr. Collins the symptoms pointed to a depression of the nervous system, and seemed to justify the remark of Gowers that the fundamental cause of all paræsthesia was a diminished resistance of the ganglionic cells. The depressing influences which Dr. Collins had mentioned certainly acted primarily upon the nerve centers and the cortex, and only as a conse-

quence of this would they lower the blood pressure and cause these vaso-motor disturbances, which were always secondary. The speaker referred to a case of paræsthesia of the abdomen that had come under her observation. The patient was a woman who had suffered from dyspepsia for about eight years. She was very thin and weighed seven-eighth pounds. She suffered from flatulence, nausea, and constipation, but the symptom that particularly depressed her and kept her in a state of misery was what she called "horrible sensations" of burning and tingling all over the abdomen, as though worms were running about under the skin. The abdominal walls were so thin that one could almost see the intestines through them. It seemed as though the intestines were not sufficiently protected and supported by the abdominal wall. An elastic bandage was ordered with which to support the abdomen. The wearing of this was followed by an immediate cessation of the disagreeable sensations; the woman was also enabled to take more nourishment and rapidly gained in strength and weight.

Dr. E. C. SÆGIN said he felt rather inclined to attribute the condition of paræsthesia to an imperfect nutrition of the cerebral or spinal nervous system. The abnormal sensations were usually distributed over a considerable area; it was very seldom that they were confined to the space supplied by a single nerve. His experience with cases of paræsthesia of the hands or arms was rather against the theory advanced by various writers that the condition was apt to follow the more or less constant immersion of these extremities in water. In one case—that of a clergyman suffering with paræsthesia of both arms and forearms—the symptoms had disappeared after a period of complete mental rest and the use of alkalies internally. There was no history of gout or a gouty diathesis in this case. Rest, particularly mental rest, the speaker had often found to be an important element in the treatment of these cases.

Dr. COLLINS stated that out of one hundred and seventy-three cases of occupation paræsthesiæ collected by him, about one hundred had been in washerwomen or needlewomen, and in a number of these cases the symptoms had been brought on by immersion of the hands in water. The fundamental cause of these abnormal sensations was probably a vaso-motor one, and when they occurred in lithæmic patients the lithæmia was possibly a coincident manifestation of the blood perversion which gave rise to the paræsthesia itself.

New Hypnotics.—Dr. WILLIAM D. GRANGER read a paper on this subject. He stated that an ideal sedative would give sleep at regularly recurring periods and for a definite period of time; this sleep would be natural, strengthening, and restorative; it would not be harmful to life or injurious to health, and it would not produce a habit, but would restore the patient to a condition of getting sleep without the use of drugs. Such a drug was unknown, and there was none that closely approached this definition.

In considering new sedative remedies, little need be said of the bromide group, which were valued mostly for their usefulness in the treatment of epilepsy. It was in the group of remedies best represented by chloral, and called the alcohol and chloroform group, that the great crop of new remedies was found. In their hypnotic effect the part of the brain representing the higher cerebral processes was first involved: first the cortex; lastly the respiratory and cardiac centers. Those were the best hypnotics that acted first and strongest upon the cortex, dulled the sensibilities, both from within and from without, lessened voluntary muscular activity, and influenced but little the vascular system and blood pressure. Among this group of hypnotics might be mentioned bromal hydrate, which was said to be more dangerous than chloral and had but little

value; and chloralamide, which was less depressing than chloral, although serious collapse had followed its use. It produced quiet and refreshing sleep, with no unfavorable after-effects. It was not so certain in its action as chloral, and it did not act so promptly. The dose was from thirty to forty-five grains. It was useful as an alternative to the other hypnotics. Chloral ammonium, in doses of from fifteen to thirty grains, was said to be non-depressive and was a good hypnotic. Hypnotism had the reputation of uniting the analgesic effects of antipyrine and the hypnotic effect of chloral. It was useful when sleeplessness and pain were combined, and the employment of opium was contraindicated. The dose of the drug was from fifteen to thirty grains. Urethane belonged to the ethyl group; it was useful in the milder cases of insomnia and for purposes of change; the dose was from twenty to thirty grains. Sonmal was an alcoholic solution of chloral and urethane, and was of little value. The dose was half a drachm. Paraldehyde could not be classed among the newer drugs; with chloralamide, it was the only drug comparable with chloral in hypnotic power. They would win their way in the most difficult cases, and were valuable in all cases of insomnia. Sulphate of duboisine was being used as a substitute for hyoscyne. It had been asserted that it gave more natural sleep and was less depressing. Sulphonal, tetronal, and trional were so closely related that they might be considered together. Almost every one had a place for the first. It had marked hypnotic power. In ordinary doses it seemed to be safe. Its long-continued use was to be avoided, not so much that it quickly lost its power, for it did not, but that it was dangerous to health. Its action was often slow, for, even if taken in the hottest water, it sometimes seemed to be precipitated in the stomach, unless quickly absorbed. Its effects were frequently long-continued, and the second dose often acted better than the first. It was a pure hypnotic, but it was less powerful than chloral. It was of little value where sleeplessness was associated with pain. Trional and tetronal were akin in many respects to sulphonal. They were all true hypnotics and were at present attracting some attention.

By study and comparison we must adapt the agent to the individual case. Experience alone would bring order out of confusion. In conclusion, we must remember that sedatives were not to be found in the pharmacopœia alone, and he who relied upon drugs exclusively for the production of sleep was in advance doomed to failure. The treatment of sleeplessness went far beyond the giving of drugs, and all hypnotic remedies—new and old—were made doubly valuable by studying the individual and using such adjuncts in the treatment of the condition as were indicated.

Dr. LYON said that among the insane sleeplessness might depend on various causes, and we should not expect any one hypnotic to meet all the indications. In the institution for the insane with which he was connected a variety of hypnotics were employed. In some cases, where there was much excitement, hyoscyne in small doses exerted a very good effect. Where the patients were considerably exhausted, chloralamide was given dissolved in whisky. Sonmal was efficacious where there was a disposition to sleep but inability to do so.

Dr. J. W. BRANNAN said he could only discuss this question from the standpoint of the general practitioner. Sulphonal, codeine, and hyoscyne were the only hypnotics with which he had had much experience. In a case of delirium tremens he had seen very good effects follow the use of hyoscyne, in doses of $\frac{1}{15}$ of a grain, the patient becoming quiet and much more comfortable. It seemed to relieve the nervous symptoms. Two or three years ago he had begun to experiment with chloralamide, but the first patient to whom he administered it had complained so severely of an intense headache after a

thirty-grain dose that he had never felt inclined to use it since. Smaller doses than this did not appear to have much effect.

Dr. SEGUN said that his experience with hypnotics, like Dr. Brannan's, was limited to patients outside of the asylum. He had always made it a rule to defer the use of narcotics as long as possible. He had found that many cases of insomnia were amenable to general treatment and encouragement and the assurance that a little sleep without the aid of drugs was better than a long sleep with them. Hyoscine or hyoscyamine was indicated where there was great motor excitability associated with insomnia, as in paresis or delirium tremens. Given hypodermically, this drug certainly did procure sleep sometimes in the most magical way. In one case he had seen $\frac{1}{10}$ of a grain completely relax a paretic and produce sleep in half an hour. The effect of the drug seemed to be a paralytic one. Sulphonal should be administered four or five hours before bedtime. The bromides should never be employed for the purpose of producing sleep.

Dr. GEORGE W. JACOBY said he had seen several patients who were in the habit of taking half a drachm of paraldehyde nightly without any particular bad effects following. One woman had continued this for over a year before she was able to break up the habit.

Dr. TERRIBERRY said that in one case of melancholia that he had seen the usual dose of paraldehyde administered had been forty-five grains. On two occasions the patient had doubled the dose and on one occasion he had tripled it; this had been followed by very decided symptoms. As regarded the time for giving sulphonal, one of his patients slept in five or ten minutes after taking the drug.

Dr. BRANNAN thought the theory had been generally accepted that sulphonal was not absorbed until it reached the intestines, and that it took three or four hours to get the effects of the drug.

Dr. L. STIEGLITZ said he had employed trional in about thirty cases in dispensary practice with very good success. The usual dose was fifteen grains. He considered it more reliable than sulphonal.

The PRESIDENT said he was in the habit of ordering sulphonal to be taken an hour before bedtime, and always in connection with some article of food. When it was given on an empty stomach its effects were much delayed. He agreed with Dr. Seguin that hyoscine should be used only where there was great motor excitement; it acted as a poison to the entire system, paralyzing all the functions. He had employed trional, but had been very much disappointed with the results obtained from it.

Dr. COLLINS said he had given trional a thorough trial, in doses of from twenty to forty grains, and obtained no results from it whatever. It was a very expensive drug and did not compare in any way with chloralamide or sulphonal.

Dr. GRANGER stated that he was in the habit of giving sulphonal from two to five hours before bedtime. In order to get its effects quickly, it should be administered in very hot water, with the hope that it would be absorbed in the stomach before precipitation occurred.

versity, etc. With Illustrations. Philadelphia: P. Blakiston, Son, & Co., 1893. Pp. xviii-9 to 636. [Price, \$3.]

It is not often that a work on insanity is published in America written by one competent, through long practical experience in the care of the insane as well as through teaching morbid psychology, to give to the profession a book which is recognized at once as a valuable contribution to literature and a trustworthy guide in dealing with the mental cases coming under the observation of the general practitioner. We remember how Audubon in his autobiography expressed his disapprobation of the closet naturalists who, never going into the field to study Nature in her own haunts, worked in their libraries and compiled books on subjects of natural history as unfamiliar to them as the nebula of Orion to a tadpole, so far as personal investigation was concerned.

Insanity is a subject with which one can not become thoroughly conversant by reading only, and it is not sufficient to see a few cases in a dispensary or office. The expert alienist must be one who, by long residence among the insane, has acquired a perfect knowledge of every phase of the morbid mind, and by practical experience has become qualified to judge of and treat the diverse psychological conditions to be met with among the insane. Dr. Stearns is an expert by virtue of his position as medical superintendent of a large asylum, and not because he chooses to call himself an expert for financial reasons. His book is the result of his being an expert alienist, and is not written as a mere advertisement to gain such a position. This work, then, must take a position similar to those of Krafft-Ebing, Kirchoff, Blandford, Clouston, Savage, and Bevan Lewis. Though not so great a book as some of these, it has an equal title to be considered authoritative. It is to be hoped that others of our American alienists—such as Hurd, Andrews, Godding, Kellogg, and Blumer—will give to the profession the valuable experiences they must have garnered during the long years of their asylum careers, for there is a dearth of works of this kind from the hands of competent American observers. We cordially recommend this volume to the profession as the best book of its kind published on this side of the Atlantic.

On Snake Poison. Its Action and its Antidote. By A. MUELLER, M.D. Sydney: L. Bruck, 1893. Pp. vi-85.

The author of this brochure has accepted the theory that snake venom acts as a specific nerve poison, depressing and more or less suspending the function of the motor-nerve centers. He therefore urges, as did L. Lanszweert in 1871, that strychnine, a motor stimulant, should be administered hypodermically in sufficient quantity to overcome the influence of the venom. The author cites a number of cases of poisoning by snake-bite that were successfully treated in this fashion. He particularly deprecates administering the strychnine in doses so small that the patient will not be benefited thereby. Within a few months we have published selections from the Australian medical journals showing that Dr. Mueller's plan of treatment is held in high favor by many practitioners, and that it is employed extensively. It is to be expected, therefore, that its real value will soon be ascertained and made known.

The Mastoid Operation, including its History, Anatomy, and Pathology. By SAMUEL ELLSWORTH ALLEN, M.D. Cincinnati: Robert Clarke & Co., 1892. Pp. vii to 111.

THE contents of this brochure are sufficiently and fully indicated by the title page. It will suffice to say of it that it is carefully and well written. The illustrations, chiefly anatomical, are excellent. The aurist, the surgeon, and the neurologist should possess it.

Book Notices.

Lectures on Mental Diseases, designed especially for Medical Students and General Practitioners. By HENRY PUTNAM STEARNS, A. M., M. D., Physician Superintendent of the Hartford Retreat, Lecturer on Mental Diseases, Yale Uni-

New Inventions, etc.

A NEW ASEPTIC VAGINAL SPECULUM.

BY D. TOD GILLIAM, M. D.,
COLUMBUS, OHIO.

I OFFER no apology for introducing this instrument, for the reason that other specula have not, or at most have only in part, met the indications for which this was devised. These indications are:

1. Asepsis.
2. Portability.
3. Ease and facility of operation.

As will be seen by the accompanying cut, it consists of three pieces: an upper and lower segment—*i. e.*, blade and handle—and the spring ratchet. The two segments are so arranged that when the blades are separated to their fullest extent and the handles are brought together they can be lifted apart for cleansing or convenience of carrying. There are no screws, springs, or other complicated device, and absolutely nothing to get out of order. The steel-spring ratchet is denatured on the side—the concealed side—and when not in use lies alongside the handle and is entirely out of the way. When in use it is opened out like a penknife at right angles to the handle with its teeth applied to the catch on the opposite handle. It is thrown on and off the catch by the index finger of the right

hand, while with the thumb and middle finger the handles are compressed to open the speculum. These movements are accomplished with the greatest ease and facility. Patients express a preference for the ratchet, claiming that it does not make them so nervous. The speculum does not become loose and rickety by use as do those put together with screws, being always firm and smooth of action. Above all is the facility with which it can be taken apart for cleansing. All that is necessary is to throw the ratchet off the catch, seize a blade in either hand, open until the handles touch each other, and lift apart. This is all done in a second. It can now be thoroughly cleansed with a brush, soap, and water, and all the evils incident to the use of an unclean instrument obviated. An instructive chapter might be written on the subject, for while all operative gynecologists are extremely cautious in the use of clean instruments, many others habitually use infected specula, and their patients pay the penalty, not always, to be sure, in fulminant sepsis, but usually by slowly advancing poison through the vagina, uterus, and tubes, with results scarcely less disastrous. In selecting the model of blades I have patterned after the Brewer, which for ease of introduction, perfect exposure of cervix, facilities for manipulation, and degree of expansion without painful pressure on the sensitive parts at the introitus vaginae is well-nigh perfection. I am indebted to Messrs. George Tiemann & Co., N. Y., for valuable suggestions in bringing the instrument to its present degree of perfection.

Miscellany.

The Influence of Prejudice and Criticism on the Progress of Gynecology was the title of a presidential address delivered at a meeting of the North of England Gynaecological and Obstetrical Society, held in Sheffield on February 17th, by Dr. W. Japp Sinclair, of Manchester, and published in the July number of the *Sheffield Medical Journal*. In the course of his address Dr. Sinclair said:

"By prejudice in this relationship I mean that mental condition, partly inherited, partly acquired, which renders us almost or altogether impervious to new ideas and new knowledge, or makes us receive it through such refracting media that we see it as it is not. The outcome in action of such a frame of mind is either to ignore methods of treatment which may be advantageous, and therefore to fail in doing the best possible for our patients, or to so modify and misapply them as to do harm with what should have been useful therapeutic instruments.

"There is an intermediate state between undiluted prejudice and the genuine critical attitude of mind which often gets credit for being the latter, of indicating strong independence of intellect, and of which we have had many distinguished concrete examples among British gynecologists—that is, the supercilious absolutely impervious frame of mind. The mind becomes a mere page of formulae, the great man himself a Tithonus among the immortals. 'The tendency of the ordinary human being is to believe too much. This inborn credulity is checked and abridged by our experience; we soon discover that we have been assuming too much, and by degrees we abate our confidence and adapt our views to the reality of things.' This is the ordinary healthy development which makes for true knowledge, but there is a class of mind which looks upon every new experience in the way of abatement of confidence as a sort of insult and very early rebounds to the other extreme. It does not become selective and critical, but impervious. It reaches a sort of mental climacteric and ceases to conceive or even to permit the approach of germs of living knowledge. Our best examples of this condition of intellect are usually distinguished members of their profession, who are mistaken for giants of logical acumen by the non-critical practitioners and the public. It is not intellectual perspicuity and sound judgment at all—it is mere pseudo-skepticism, the worst form of prejudice, because it is the most obstructive and mischievous.

"As to criticism in reference to the class of subject with which the gynecologist has to deal. It is of course the same as applied to all medical subjects; but there are some peculiarities in its scope and applications which we may note and exemplify. It implies, first of all, a certain amount of knowledge and experience as its basis, such as the average mind may become furnished with by a certain amount of industry and from the lapse of time. It implies a certain clearness of intellectual vision as well as intellectual honesty combined with the power to suppress the emotional side, which always tends to bias the intellect and lead to false conclusions. If it is to do the highest service in the cause of medical science it must be disinterested; and this is the criterion, as far as our ordinary experience goes, with which medical criticism has the greatest difficulty in complying. 'The first essential of knowledge is that it be true.' The truth or falsehood of statements contained in an ostensible contribution to knowledge is to be made out for ordinary practical purposes by analysis and comparison of the elements contained in it with knowledge already acquired. If there be anywhere contradictions there is falsehood. In a practical subject we can not expect all to meet to the fullest extent the logical criteria of truth, but the function of criticism here is to estimate the relative amount of truth and error; for on this relation depends the value of the presumed contribution to knowledge.

"If this process be difficult when we are applying the criticism to the work of a friend, or disciple, or teacher, how much more severe the task must be in dealing with our own work! Indeed, it is the want of intellectual honesty and clearness in seeing ourselves as others see us which chiefly stands in the way of the application of that criticism which would prevent so many contributions to medical

literature from ever seeing the light. Few men have the gift of being hard on themselves. If the intellectual qualities required for the maintenance of this attitude were more generally diffused, medical literature, especially of the hebdomadal journalistic sort, would be less copious and tedious; but with the loss of material we should also have to count on some loss of amusement, and of that lazy semi-derivative interest which our weekly journals so largely afford us."

"We can hold such conservatism [as that of the late Dr. Matthews Duncan] in respect, for it is honest from the moral side, and it almost invariably implies a large endowment of the power of analysis and sense of proportion from the intellectual side. But there is a common force at work and influence concerning which we can have nothing but the strongest terms of condemnation and resentment. This is the influence of *personal animosity* disguised in the terms of apparent impartial criticism. Take one or two illustrations, which I shall not set down as positively proved examples of bias of judgment by personal ill-will. You can judge for yourselves.

"(1) You are aware that nearly twenty years ago Emmet, of New York, proposed a simple operation for the cure of lacerations of the cervix uteri and the changes in the cervical portion of the uterus which result from these injuries. It was an operation which 'caught on' in America and was abused, but it did not obtain the recognition which it deserved in England. In a recent work on gynecology there is a page which might be an excerpt from a mediæval monograph, so obsolete and erroneous are its statements on the subject of 'ulceration of the womb.' Referring to laceration, it goes on to say: 'A well-known American gynecologist has conceived the idea that this rent is the cause of all the mischief, instead of being a mere incident which is not of the slightest consequence in itself. A great flood of operations has in consequence gone through the practice of gynecology of recent years for the stitching up of this innocent fissure. The real trouble is in the subinvolution and the consequent chronic metritis, as we shall see by and by, and nothing more useless than "Emmet's operation" has ever been introduced into surgical practice.' Now, this language does not sound like fair criticism; it has an emotional ring about it. To one who has frequently performed Emmet's operation, and seen it cure cases in which the tortures of the ordinary treatment of 'ulceration' had been applied for years, it absolutely and completely discredits the judgment of the writer. But the key to the vigor of the language used seems to me to do much more; it forces upon our attention the element of personal animosity in the guise of criticism. When calling upon Emmet a few years ago I learned the details of a personal quarrel between the author of the operation and the author of the book. The merits of a quarrel are never known till both sides have stated all the truth, but, as far as I understood them, the American gynecologist might well be angry and sin not.

"(2) In spite of the prejudice excited against it by American ex-cuses, Emmet's operation has been adopted in Germany to a considerable extent, much more widely than in the United Kingdom. One voice, as far as I can hear, only one, is raised against it, and the paper in which objections were urged to the operation called forth several strongly worded remonstrances, notably that of Sanger, of Leipsic. In 1887 a paper was read at a medical congress at Wiesbaden on the subject of laceration of the cervix, and the writer gave it as his opinion that laceration of the cervix and Emmet's useless operation would disappear from our nosology and practice. Now, probably few who heard or read that paper were aware that the originator of the operation and the critic were formerly rivals in gynecological practice in the same city, and that the Irishman and the German had been on unfriendly terms over an operation introduced and practiced for a short time by the German and anathematized by the Irishman. These incidents speak for themselves. If the criticisms and the personal hostility are not cause and effect, it is a pity for the dignity of gynecological practice that the critics, knowing that grounds of offense existed, did not exhibit a little more reticence, to say nothing of justice, in their strictures."

"Another aspect of practice under which we see the influence of bias is in the hostility of those whose names have become associated with an operation or method of treatment to the introduction of any modification or change, or even improvement. It is the bias of the *beati possidentes*. Here, as a rule, prejudice attains its most respectable position; it tries to use the language of criticism, but its sayings are the mere conventionalities of the formalist who assumes he has reached finality. It is loud and confident, but it means little, and occasionally becomes almost fatuous. It is Saug the joiner that we hear, not the lion; and yet the voice has occasionally succeeded in frightening the gynecological crowd!

"(1) Take, for example, in the first place, the reception given to the electric treatment of uterine disease, especially fibroid tumors, in this country. Contrast the moderation of the language in which Apostoli introduced his careful experimental work to the profession in England with the language of Mr. Knowsley Thornton and Mr. Lawson Tait, as representing the interests opposed to it, and you can not but feel ashamed of the representatives of English gynecological surgery. Mr. Lawson Tait's references to his work of over twenty years before, and his testimonials in support thereof, are a thing *pour rire*, but his attack on M. Apostoli's reputation and professional position in Paris belongs to a different category. I am not discussing the merits of the electric treatment of uterine disease; I merely give illustrations of the methods by which science is not advanced. It is a pleasure to turn from the speeches and letters of the surgeons named to such specimens of the better criticism, the results of thought and experience and knowledge exhibited in the speeches of Dr. Playfair and Dr. Inglis Parsons, when the subject was under discussion at the meeting of the British Medical Association at Leeds in 1889. Much has been done since then in modifying methods of application of the treatment and opinions concerning it, but Dr. Playfair's first point in his summary still stands as just and true as when it was first uttered. 'The continuous current is capable of effecting much good in certain selected cases, otherwise little amenable to treatment; and its introduction is, therefore, a distinct gain to gynecology.' His objections and modifications of this statement stand equally true. I have no hesitation in saying that on the question of Apostoli's treatment the profession in England have been simply bullied out of the belief in their own observations and judgment on a method of dealing with disease which was *prima facie* not unscientific.

"It has been alleged by one of the most bitter opponents of Apostoli that he was unknown in Paris in 1888. I can speak from personal knowledge that he was respected and consulted by some of the chief surgeons in 1889; and in the end of that year Lucas-Championnière published his results strongly supporting Apostoli, while he admitted, as Apostoli did himself, that a considerable proportion of cases were not amenable to his treatment.

"How true it is that under the influence of prejudice, which may take the form of self-interest under the most unlikely circumstances, we succeed in seeing what we went out to look for!

"(2) Another illustration of how the tenacity of opinion in favor of some method of treatment or operation with which we are familiar and satisfied stands in the way of further improvement is to be found also in the surgical treatment of fibro-myomatous tumors of the uterus. Among the best-known operators, the men who see their way to go through the largest amount of material, are, I presume, Mr. Knowsley Thornton and Mr. Lawson Tait. They stick to the barbarous appliance called Kœberlé's *serre-naud*. Its application merely consists in constricting some part of the uterus, below the tumor if possible, with a piano-wire, and tightening up the rope from hour to hour or from day to day until the gangrenous mass falls off. This is the extraperitoneal method, and fairly ranks with the use of the clamp in ovariectomy. Attempts have been made from time to time to apply an intraperitoneal method. I have taken a deep interest in the efforts at improvement, and have carefully watched the reports of cases. There is much reason to believe that before long the intraperitoneal method will be recognized as the best in the few cases in which operation is justifiable, and the barbarous old appliances discarded. Yet even so recently as the last meeting of the British Medical Association at Nottingham,

what help toward progress do we get from the hysterectomists? Mr. Knowsley Thornton says (*British Medical Journal*, February 11, 1893): 'Theoretically, this (the intraperitoneal) is a perfect method . . . ; but practically it has certain great difficulties and dangers.' These, he says, are prevention of hemorrhage immediately, or later, 'as the uterine tissues contract,' and making 'the inside of the stump thoroughly aseptic.' The last objection is put on the ground that the mucous membrane, which, he does not seem to be aware, contains no bacteria, 'may acquire putrid material.'

"During a discussion on the 'present position of abdominal surgery' at the Medical Society of London three years ago, the question of intraperitoneal treatment of the stump in hysterectomy for fibroids was referred to. Mr. Lawson Tait severely remarked upon some observations of Mr. Treves; he said: 'He [Mr. Treves] says that he has made flaps, tied vessels, fastened the flaps together, and dropped the stump back in the abdomen with good results. This only means that his experience has been small and his fate exceptionally happy. It is the "stage" method of Schröder, and even in his hands had a mortality of thirty per cent.; and all of us have tried it with most disastrous results. A uterine stump from which a myoma has been removed is unlike anything else in the human body known to me. It is as hard as cartilage and as brittle as cheese, so that a ligature will cut through it, or it is so completely infiltrated with serum that a tightened ligature will be quite loose in a few hours and the vessels will bleed even at the end of forty-eight hours.' Prejudice, and it is a compliment to use the term here, could hardly go further. If Mr. Treves's experience has been small, what could Mr. Tait's have been? Where has he published those disastrous results? His picture of cheesy flaps and bleeding vessels must be purely imaginary. His reference to Schröder is confident but unsupportable by evidence. Nobody has ever described exactly the final form of Schröder's operation; as far as we know it, it was a very rudimentary attempt at an intraperitoneal method. It was not a flap operation at all. It came nearer to what Zweifel has described, and his is a genuine 'stage' operation—a very different matter."

"Let us now consider for a moment an intermediate condition of the professional mind before taking some illustrations of the influence of criticism in its proper field of influence. We pride ourselves on our intellectual attitude toward new-fangled things, our medical skepticism, which as applied to other subjects gave rise to the mediaeval proverb *Tres medici, duo septicii*. No sentiment is more popular among us than the oft-quoted 'Nullius in verba magistri,' but the *verba magistri* are just as potent now in a more restricted province as among the schoolmen. (1) Take, for example, some episodes in the history of intra-uterine medication. We all remember the use of fuming nitric acid in the treatment of endometritis. In a book published in 1871 you may read 'its application causes very little, indeed in general, no pain; it produces but a superficial slough, and has a wonderful effect in bringing about a healthy condition of the mucous membrane lining the body and cervix uteri, etc.' 'Such is the treatment I nearly invariably adopt.' The author recommends the protection of the lower part of the canal and the os externum by means of the glass cannula, with as much confidence as if no such thing as capillarity had ever been heard of. We all remember how we employed this powerful chemical agent, and I at any rate could tell of some serious mischances, even though the patients all escaped with their lives. Still we continued under the influence of authority, even though the *magister* had discredited his judgment by describing the curette as 'an unscientific instrument and ill adapted to obtain the object in view.'

"The same author made another contribution to the subject of intra-uterine medication; he read a paper at a meeting of the British Medical Association in 1884. By that time he had nearly given up the use of nitric acid, only using it in three per cent. of his cases. He had adopted 'iodized phenol' on the recommendation of Dr. Battey, of Georgia, who considered it a cure for epithelioma of the cervix, and *a fortiori* of simpler forms of disease of the uterus. 'Iodized phenol' is merely iodine dissolved in carbolic acid. Why should it be more effective than carbolic acid, which it chiefly is? It is admitted that iodine

alone has little influence on the endometrium. This strong escharotic was injected into the uterine cavity without previous dilatation. Although no explanation was given of the abandonment of nitric acid, the new remedy was at once adopted, and I believe it is in general use. Yet it has many disadvantages as compared with other substances which may be employed for intra-uterine medication. There is no known agent which acts instantaneously in neutralizing the excess of fluid employed, as we have in the case of nitrate of silver, nitric acid, or chloride of zinc; and no attempt has ever been made to show that this serious drawback is made up for by any countervailing advantage. There has been absolutely no criticism applied to the subject. I do not say the treatment is bad; I believe it is not the best, and considering its drawbacks and the greater convenience and equal or better effect of other agents, I think 'iodized phenol' ought to be given up, as uncertain, uncontrollable, and therefore unsafe and unsatisfactory.

"How we sometimes allow ourselves to drift with every wind of 'doctrine' is well illustrated by the history of gynecology concerning *suture of the perineum*. The late Dr. Aveling, in a learned address, published in the first volume of the *British Gynecological Journal*, called attention to the fact that the writer of a book published in 1490 recommended the introduction of silk sutures in complete rupture of the perineum. The practice appears to have varied according to the fashion set by the masters up to the middle of last century, when Smellie published his work. Smellie's advice is definite and distinct, 'as soon as possible' to introduce deep sutures into the lacerated perineum. Toward the end of last century, however, the practice was falling into abeyance, and Burns, whose third edition was published in 1814, says that sutures ought to be resorted to if union can not be otherwise obtained. The practice of using sutures fell off again in this country, and only became general under German or Continental influence in the last quarter of a century. We still meet elderly practitioners who, in spite of all experience to the contrary, confidently state that lacerations of the perineum always unite by themselves. It is, on the contrary, the universal experience that they never completely heal without sutures; but with ordinary antiseptic precautions they always heal after suturing. And yet, in spite of this universal experience of men engaged in obstetric practice, we have a recent pronouncement in favor of the remote operation by a gynecological surgeon who can not have had many opportunities of observing how women suffer from complete rupture during the weeks after confinement when healing is 'left to Nature.'

"When Dr. Alexander, of Liverpool, brought before the notice of the profession an operation which he asserted, with a considerable amount of well-arranged and well-stated evidence, was efficacious in curing retroflexion of the uterus, he at once arrested the attention of all specialists in diseases of women. Whether it was a new thing or a revival did not matter to anybody but to Dr. Alexander. He should have solaced himself on that point with the reflection that it is impossible against the evidence always produced to disprove that original surgical work always has its birth in France. Many questions were naturally asked about the operation, and objections were raised which the author might have taken in a more philosophic fashion. However, no answer could be obtained except from evidence of the results of practice. 'To act is so easy; to think is so hard.' We all went into action, and left the reasoning to follow. Soon from all hands allegations as well as questions began to demand attention. It was alleged by men whose professional character would bear the strain that the operation was difficult to perform; and the author replied in vain that it depends upon the skill of the operator. It was alleged by men who obviously only sought to do their best for their patients that the results were not permanent, and this no doubt had its effects even against the author's assurance that his results were permanent. It was alleged in objection to the operation that it caused great pain and distress, that there was suppuration almost invariably which continued a long time, and that the patient must continue in the recumbent position for many weeks if a good result was to be obtained. These objections came from all parts of Europe and America, and those were by no means few or feeble which came from France, where the operation had been rather

warmly taken up. Then injudicious advocacy did its work. One operator assured the surgical profession that he could tickle out the ends of the round ligaments through a half-inch incision in any patient. This was an assertion simply calculated to anger the less gifted who had sometimes to dissect from the ring along the course of the ligaments in search of them, and not always successfully.

"I do not remember a proceeding introduced to the notice of the profession which received a fuller and fairer discussion and less unfriendly and biased criticism. After much action came the reflection which found expression both in word and practice, and now the operation is, rightly I believe, relegated to the class of justifiable proceedings which have rather a narrow field of usefulness, because of the reasonable objections to the operation under the most favorable conditions, and also because of the numerous alternatives to it.

"*The Prejudice of International Rivalry.*—The diligent reader of the special literature of France and Germany can hardly miss observing the barrier to universal acceptance of therapeutic measures which the bitter rivalry between the two countries for many years has raised.

"France was slow in accepting abdominal section for diseased ovaries, which came to it from Germany. The Germans were unwilling for long to accept the curette and the various appliances and measures for intra-uterine medication, which came originally from France.

"France was the home of abdominal operations for fibroid tumors, associated with the names of Kœberlé and Péan, and it was long before hysterectomy was taken up in Germany.

"Endless examples of less important differences could be mentioned resulting in delays, but not in permanent obstruction to the progress of gynecology.

"When both nations take up a new operation or therapeutic measure simultaneously and with ardor, surely there must be something in it which appeals to the common sense of all. Such an operation we have in the proceeding for the cure of retroflexion of the uterus with adhesions, which the Germans call *ventrofixation of the uterus* and the French gynecologists *hystéropexie*.

"The general adoption of this operation on the Continent naturally leads one to remark on our insular prejudice or wisdom, for so far it is almost literally true to say we will have nothing to do with it."

The American Chemical Society.—The following resolution was adopted by the council on June 7, 1893:

Resolved, That the general meeting of the American Chemical Society for the summer of 1893 be held in Chicago at such date as may be determined by the committee appointed by the society to co-operate with the World's Fair Auxiliary of the Columbian Exposition in arranging for an International Congress of Chemists.

In accordance with the terms of this resolution, the committee to co-operate with the World's Fair Auxiliary have determined that the fifth general meeting of the society shall be held during a period beginning August 21, 1893, in conjunction with the World's Congress of Chemists to be held under the auspices of the World's Fair Auxiliary and the American Chemical Society.

The committee desire to call to the attention of the members of the society and of American chemists generally the fact that in view of the large number of eminent chemists, home and foreign, who have already signified an intention to attend the World's Congress of Chemists, and the valuable character of the papers that will be presented, this meeting will doubtless be the most important gathering ever held by chemists in the United States. The time and place are therefore particularly auspicious, and the promise of a most successful and enjoyable occasion very great. The meetings will be open to all chemists in good standing, and in order that a programme of proceedings may be arranged in advance, it is earnestly requested that those who desire to offer papers will forward titles thereof as early as August 1st, to Professor William McMurtrie, 106 Wall Street, New York, care of the New York Tartar Company.

It is also the hope of the committee that in view of the important part taken by the American Chemical Society in calling the World's Congress of Chemists, the society will be represented by a large number of its members in this meeting. This is due to the foreign chemists who have accepted the invitations extended by the society.

In matters of transportation to, and quarters in, Chicago, members of the society will have all the advantages provided for those who will attend the World's Congress of Chemists. Those desiring information with this regard may obtain it by addressing Professor John H. Long, No. 2421 Dearborn Avenue, Chicago.

It is requested that as soon as possible after their arrival in Chicago, members will report at the Congress Headquarters in the Art Institute Building, Lake Front and Adams Street, and register their names and Chicago addresses so that they may receive without delay such notices and information as the committees may have to distribute at that time.

W. McMURTRIE,
C. F. CHANDLER,
A. B. PRESCOTT,
C. E. MUNROE,
H. W. WILEY,

[Signed.]

Committee to co-operate with
the World's Fair Auxiliary.

To Contributors and Correspondents.—*The attention of all who purpose favoring us with communications is respectfully called to the following:*

Authors of articles intended for publication under the head of "original contributions" are respectfully informed that, in accepting such articles, we always do so with the understanding that the following conditions are to be observed: (1) when a manuscript is sent to this journal, a similar manuscript or any abstract thereof must not be or have been sent to any other periodical, unless we are specially notified of the fact at the time the article is sent to us; (2) accepted articles are subject to the customary rules of editorial revision, and will be published as promptly as our other engagements will admit of—we can not engage to publish an article in any specified issue; (3) any conditions which an author wishes complied with must be distinctly stated in a communication accompanying the manuscript, and no new conditions can be considered after the manuscript has been put into the type-setters' hands. We are often constrained to decline articles which, although they may be creditable to their authors, are not suitable for publication in this journal, either because they are too long, or are loaded with tabular matter or prolix histories of cases, or deal with subjects of little interest to the medical profession at large. We can not enter into any correspondence concerning our reasons for declining an article.

All letters, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication. No attention will be paid to anonymous communications. Hereafter, correspondents asking for information that we are capable of giving, and that can properly be given in this journal, will be answered by number, a private communication being previously sent to each correspondent informing him under what number the answer to his note is to be looked for. All communications not intended for publication under the author's name are treated as strictly confidential. We can not give advice to laymen as to particular cases or recommend individual practitioners.

Secretaries of medical societies will confer a favor by keeping us informed of the dates of their societies' regular meetings. Brief notifications of matters that are expected to come up at particular meetings will be inserted when they are received in time.

Newspapers and other publications containing matter which the person sending them desires to bring to our notice should be marked. Members of the profession who send us information of matters of interest to our readers will be considered as doing them and us a favor, and, if the space at our command admits of it, we shall take pleasure in inserting the substance of such communications.

All communications intended for the editor should be addressed to him in care of the publishers.

All communications relating to the business of the journal should be addressed to the publishers.

Contributors who wish to order REPRINTS of their articles should do so on a blank prepared for that purpose, which will be sent to them by the publishers on receipt of a request to that effect. The order should be sent to the publishers, and not to the editor.

Original Communications.

GOUTY RETINITIS,

CHORIO-RETINITIS, AND NEURO-RETINITIS.*

By CHARLES STEDMAN BULL, M. D.,

SURGEON TO THE NEW YORK EYE INFIRMARY;

PROFESSOR OF OPHTHALMOLOGY IN THE UNIVERSITY OF THE CITY OF NEW YORK.

DURING the last few years my attention has been attracted by certain lesions occurring in the fundus in gouty patients, and the more I have studied these cases the greater has my interest in them grown. The pathological condition of the blood in gout does not always work in a way that readily attracts attention, and this is particularly true in regard to the eye. Most authors who refer to retinal complications occurring in the course of gout only mention a hæmorrhagic retinitis as being the most frequent retinal complication. Thus Nettleship says: "Hæmorrhagic retinitis is more commonly met with in gouty persons than in others. It may be unioocular or binocular. The children or descendants of gouty persons, without being themselves subject to gout, are liable in early life to this insidious form of eye disease" (*Diseases of the Eye*, fourth edition, p. 445).

Other authors refer to the subject in a still more casual or general way. Lychon speaks of intra-ocular hæmorrhages and neuro-retinitis as due to gout (*Thèse de Paris*, 1855).

F. Gauté says that there is a gouty retinitis which strongly resembles certain types of syphilitic retinitis, and which may or may not be accompanied by opacities of the vitreous, retinal hæmorrhages, migraine, and zona ophthalmica (*Thèse de Paris*, 1881).

Jonathan Hutchinson, in an article on Primary Intra-ocular Hæmorrhage, says that gouty persons are prone to hæmorrhages, venous obstruction, and irregularities in circulation, due to a too large arterial pressure and a relaxed condition of the vascular walls, and that vitreous opacities may in these cases be constantly present. According to him, there are four possible sources of these phenomena—viz., (1) changes in the blood; (2) increased arterial tension; (3) disease of the walls of the blood-vessels; (4) hypertrophy of the heart. He considers that both low tension and high tension are alike compatible with liability to rupture of the capillaries. A condition of loss of balance is easily induced, as the vessels are not well under vaso-motor control. The risks of rupture of the capillaries will be increased if there be hypertrophy of the heart or weakness of the walls of the blood-vessels (*Transactions of the Ophthalmological Society of the United Kingdom*, vol. i, p. 26).

Gowers speaks more positively in regard to retinal lesions in gout. He believes that spontaneous inflammation of nerve trunks and plexuses on one side only, and recurring after the age of thirty or forty, is seldom due to any other cause than gout. This always means primary perineuritis. Still, inflammation of the sheath of the optic nerve behind the eye is less common in ordinary gout than

inflammation of the retina. Gowers thinks the characteristics of these cases are the greater degree of disturbance of the vision than corresponds to the visible changes in the optic disc, the tendency to irregular defects in the field of vision, and the strong tendency to lesion of the other optic nerve by an independent symmetrical morbid process (*Medical Ophthalmoscopy*, third edition, 1890).

Galezowski says that in this disease the changes may begin in the retina and extend to the chorioid, and give rise to a retino-chorioiditis, characterized by an alteration in their vessels and deposits in and outside their walls. When the retina is alone involved there exist only vascular alterations. Atheroma (?) is frequent in the retinal vessels of gouty people, and usually attacks persons of advanced years—from seventy to seventy-five. The papilla is ordinarily not involved, but all around the macula and along the vessels are brilliant patches of exudation, generally along the arteries. The rest of the retina may remain intact. The lesion is generally unilateral. The subjective symptoms are the same as those of ordinary retinitis. Gouty retino-chorioiditis occupies the central zone of the fundus, is circumscribed posteriorly, the exudation is usually extensive, with hæmorrhages and sometimes pigmentary deposits. The disease develops slowly, usually involves both eyes, and never ends in total blindness, as the periphery of the retina is rarely affected (*Annali di ottalmologia*, xii, p. 199). We know that the retinal hæmorrhages met with in gouty persons may involve one or both eyes, and are of sudden onset. Small flame-shaped hæmorrhages are scattered all over the fundus, and if the extravasations are punctate they have striated margins. The disc may be hazy, but there is no such regular glistening-white deposit as is met with in so-called retinitis nephritica. The veins are usually engorged and tortuous and more or less indistinct by an effusion of blood into their sheaths. It seems hardly justifiable to separate this group of cases sharply from other forms of retinal hæmorrhage associated with renal disease and diabetes, since renal disease is so often a concomitant of gouty cases. The influence of the cardio-vascular system must be carefully considered in these patients. Hutchinson thinks that these hæmorrhages are due rather to venous obstruction, such as thrombosis of the retinal vein, than to arterial disease, as more explanatory of the suddenness of the attacks.

The effects of the poison of gout upon the vascular system are now generally recognized to be (1) a high blood pressure in the arteries; (2) hypertrophy of the left ventricle; (3) hard incompressible arteries undergoing atheromatous change. From these result either apoplexy by rupture of a blood-vessel, or aneurysm by dilatation of the vessel, or angina pectoris, or fatty degeneration of the heart.

Some years ago Dr. George Johnson found, in cases of chronic renal disease, a thickening of the muscular wall of small arteries and arterioles, which he attributed to increased contraction of the muscular coat, due to the abnormal qualities of the contained circulating blood. This led to a damming of the blood in the arteries, a rise of blood pressure, increased action of the heart in systole, and hyper-

* Read before the American Ophthalmological Society, July 19, 1893.

trophy of the left ventricle. Mahomed has since shown that high arterial tension is not a consequence but an antecedent of kidney disease. High blood pressure within the arteries is connected with spasm of the arterioles and hypertrophy of the thin muscular coat, and leads to hypertrophy of the left ventricle. The overdistention of the arteries causes a growth of connective tissue under the tunica interna of the arteries, which we call atheroma. Then follows hypertrophy, with failing heart and arteries.

There seems to be no doubt that a gouty optic neuritis is occasionally met with, for Hutchinson and others have reported cases, and it is probable that the perineurium is first affected, leading to thickening and compression of the bundles of nerve fibers, the adjacent lymph spaces being filled with an exudation from the blood-vessels.

There is also but little doubt that a gouty phlebitis of the central retinal vein and its branches is occasionally met with. This leads to a roughening of the surface of the internal lining, which favors the occurrence of thrombosis. In these cases, owing to the gouty poison, there is naturally hyperinosis and tendency of the blood to clot. Duckworth thinks that there is probably a determination of acid urates to the part, which acts as the directly exciting cause.

Most of our knowledge of this condition of the arteries has been gained from Thoma's investigations. He concluded that arterio-sclerosis is caused by some general disturbances of nutrition, which are partly the result of infection, intoxication, and other pathological changes of varying kinds, and partly the accompaniment of senile changes. These general disturbances of nutrition cause not only disease of the arteries, but also of the veins and capillaries. In the arteries the middle coat is thinned, and there is a loss of elasticity by a diminution of the resistance which the wall of the vessel opposes to the stretching of the blood pressure. The vessel is stretched in all directions, it widens, and its lengthening leads to tortuosity. The widening of the lumen is followed by a connective-tissue deposit in the intima, and this is followed in turn by a number of retrogressive changes, such as fatty degeneration, or calcareous degeneration, or hyaline degeneration. Similar changes occur in the veins. In the capillaries there is an increase in the porosity of the capillary wall and cedematous infiltration of the tissue. The important consequences of this so-called angio-sclerosis are varicose dilatation of the veins and aneurysms. In the beginning of the process there is a loss of elasticity of the vascular wall, shown in life by a soft, high pulse, and pulsation and tortuosity of the arteries, notably of the retina. At this stage there is the greatest danger of rupture of the arteries. Later the vessels, by reason of the deposit of connective tissue in the intima, become firm and rigid.

In endeavoring to explain the results of those vascular changes we must consider three factors: (1) The shortening of the median coat; (2) compensatory endarteritis; (3) atrophy of the muscular coat of the artery. A permanent slowing of the blood current in an artery is followed by a narrowing of its caliber, which is brought about in a regular way, on the one hand by a contraction of the tunica media, and on the other hand by a deposit of connective tis-

sue in the tunica intima. Any retardation of the blood current in the arteries and veins which is not completely and at once neutralized by a corresponding contraction of the media leads to a hyperæmia of the vasa vasorum and to a new growth of connective tissue in the intima, which narrows the lumen of the affected vessel, and consequently does away more or less completely with the normal rapidity of the current. With this there is associated later a similar formation in the media and adventitia. The first recognized departure from the normal condition of a vessel consists in the stretching of the media, which is the cause of the diffuse, primary arterio-sclerosis, characterized by a dilatation and tortuosity of the arteries, by an eccentric hypertrophy of the media, and by a diffuse, compensatory, fibrous thickening of the intima. All of these changes I have repeatedly seen develop in the retina of gouty patients while under treatment. We know from the investigations of Loring that arterio-sclerosis in the eye can be followed for years, and the gradual obliteration of the vessel traced. Evidences of its presence are the tortuosity of the arteries, pulsation in their blood current, opacities in their walls, often a diminished lumen, hyaline degeneration of some of the vessels on the papilla, aneurysm of the central artery, and varicose retinal veins. More rarely there occur complete obliteration of an artery and thickening of the walls of the veins with partial obliteration of their lumen. Changes like these in the central retinal artery and its branches are probably associated with similar changes in the ophthalmic artery and internal carotid.

More recently observers have begun to recognize corresponding changes in the veins, and to regard phlebo-sclerosis as a systemic disease analogous to diffuse arterio-sclerosis. Some years ago Sack described a condition which he called a chronic fibrous endophlebitis, and stated that it not infrequently appeared as a local lesion in consequence of local stasis in the venous system. Huchard, in 1889, and Spillmann, in 1890, both used the term phlebo-sclerosis to describe this process. According to the latter, phlebo-sclerosis in gouty persons may be both circumscribed and diffuse, the latter being met with in the small veins. The same pathological changes occur in the vasa vasorum, with an abnormal development of nuclei around the small capillaries. His investigations show that the venous lesions develop progressively and simultaneously with the arterio-sclerosis, without, however, ever ending in the profound alterations which change the arteries into rigid tubes (*Gaz. heb. de méd. et de chir.*, Oct. 11, 1890).

Pokrovsky has made still more extensive investigations upon thirty cases. Macroscopically the veins showed no marked changes, though they were sometimes found studded with circumscribed, irregular, elevated white patches, both soft and hard. He concluded from his investigations that chronic inflammation of the arteries, so-called arterio-sclerosis or chronic endarteritis deformans, is accompanied by analogous though less intense morbid changes in the veins. The most frequent process is a compensatory, diffuse, fibroid endophlebitis, analogous to Thoma's compensatory diffuse endarteritis. The endophlebitis commences

with the appearance in the intima of the veins of many young cells, which are subsequently transformed into fibrous connective tissue. The young cells are supplied mainly by proliferation of the elements of the intima. Besides this diffuse inflammation, there is a circumscribed nodose thickening of the venous walls, which is usually associated with retrogressive metamorphosis and is analogous to the nodose arterio-sclerosis. As regards the regressive changes, the most frequent is hyaline degeneration, met with in all the coats of the veins. Fatty degeneration rarely occurs. In cases of intense endophlebitis the media frequently undergoes an interstitial inflammatory process, with the formation of numerous blood-vessels, profuse cellular infiltration, and proliferation of interstitial connective tissue. The adventitia is usually affected in a slighter degree (*London Medical Record*, Aug. 20, 1890).

Raehlmann's paper on the changes in the retinal vessels in general angio-sclerosis also calls attention to the changes in the veins. In about half the cases examined there were corresponding changes in both arteries and veins of the retina. The veins were relatively widened, always had a whitish edge or margin, and in some cases appeared changed into white cords, and the blood column seemed entirely interrupted. In some places varicose dilatations were distinctly visible (*Zeitschr. für klin. Med.*, xvi, 1889). His investigations have shown that while extensive sclerosis of the vascular wall is usually accompanied by a hyaline degeneration of the tissue elements, showing like white lines along the blood column, it may sometimes be invisible with the ophthalmoscope. Raehlmann has noted the following changes in the retinal arteries: 1. Distortion and narrowing, sometimes so marked as to simulate the condition met with in atrophy of the optic nerve, but usually accompanied by a normal field for form and color and normal acuity of vision. 2. White lines along the arteries, due sometimes to cloudiness alone, and sometimes to that and thickening together. This consists microscopically in an alteration of the adventitia, by which the wall of the vessel is thickened, without narrowing of its lumen, and also in a hyaline degeneration of the arterial wall. 3. Local or patchy narrowing of the arteries, separated from each other by spaces of varying length in which the vessel has its normal caliber, the result of deposit in the vascular wall. In diffuse arterio-sclerosis the wall of the vessel has a more homogeneous, yellowish, glistening appearance, in which the structure elements are less distinguishable. In some places he has seen patches of arterio-sclerosis nodosa, occurring generally at the point of bifurcation. It is still an open question with Raehlmann how far these patchy proliferations of the intima—round, or fusiform, or irregular, as the case may be—have to do with the development of embolic and thrombotic processes. The vascular tension is probably increased in front of these narrowed spots, while it is diminished behind them. Complete closure of the lumen of an artery as a result of endarteritis nodosa occurs frequently. 4. Aneurysms of the central artery and its branches.

In the venous system of the retina Raehlmann found white lines along the veins, narrowing of their lumen in

local, circumscribed spots, and varicose dilatations also in circumscribed spots. He also met with pulsation in both arteries and veins, more frequently in the latter.

Goldzieher has described the same pathological conditions in the eyes of a patient whom he first examined clinically, and whose eyes he subsequently examined microscopically (*Contrib. f. prakt. Aug.*, 1889). In one eye of this patient, besides the changes in and about the blood-vessels, there was a circle of bright, glistening spots of varying size and shape, whitish-yellow in color and without pigmented border, symmetrically grouped around the macula, which was intact. These patches proved to be entirely in the retina. These spots of exudation he has seen in other cases, and they were accompanied by impaired vision and an irregular central scotoma. He says that in these cases the disc and periphery of the retina are usually normal, and that the course of the disease is chronic and painless, and to these points I wish to draw particular attention, as they correspond closely with the clinical and microscopical appearances of the cases on which this paper is based.

CASE I.—In June, 1889, I was consulted by a gentleman, aged seventy-two, at the request of his family physician. Four years previously he had consulted Dr. C. R. Agnew, who found signs of what he called chorio-retinitis in both eyes, most marked in the left eye. After a careful examination of his case, Dr. Agnew came to the conclusion that the trouble was due to gout, and recommended strict dietetic treatment. This was not carried out with any regularity by the patient, and the condition in the eyes grew slowly worse. The main difficulty had been an inability to read any small type. Some months before I saw him he first noticed that he could not see objects at a moderate distance as distinctly as usual, and, on testing each eye separately, he found that the main defect was in the left eye. This defect has slowly but steadily increased. I found, on examination, R. E. V. = $\frac{2}{3}$, with sph. + D. 1.50 = $\frac{2}{3}$. L. E. V. = $\frac{2}{3}$, unimproved, and decidedly better eccentrically. He could still read Jaeger 6, with sph. + D. 5.50 with the right eye. The tension was normal in both eyes. The media were perfectly clear in both eyes. A careful perimetric examination of the field of vision showed the presence of a small, irregular central scotoma for form and color in the right eye, and a very large scotoma in the left eye.

The ophthalmoscopic examination revealed a very interesting condition of the fundus. The outline of the discs was very much blurred, resembling the first stage of choked disc, but without the edematous swelling. In the left eye the arteries were much diminished in caliber, in several places the lumen being reduced to the merest thread, and requiring the closest examination to see the minute blood column that still existed. The white lines along the vessels, both arteries and veins, were very broad and distinct, and extended from the center of the papilla well out toward the periphery. In places the veins seemed dilated like a fusiform aneurysm, the vein on both sides of the dilatation being reduced in caliber. There were numerous patches of yellowish-white exudation in the retina of varying size and shape, mainly grouped about the region of the macula and disc, but with no systematic arrangement, and one patch of considerable size in the macula itself. There were no hæmorrhages in either eye. All these spots of exudation were in the inner layers of the retina. In the right eye the arterial and exudative changes were much less marked. The white lines along the arteries and veins extended for only a short distance

beyond the margin of the disc, and, though the lumen of both sets of vessels was in places diminished, there was no apparent disappearance of the column of blood and no fusiform or nodose dilatation of the vessels. The appearance of the optic disc, however, differed but little from that in the left eye. The action of the heart was strong, but somewhat irregular. There was a faint aortic and mitral murmur, and marked degeneration of the temporal and radial arteries. The urine had a specific gravity of 1.018, was slightly turbid, light amber in color, and contained neither albumin nor sugar. There were no casts, but it was loaded with uric-acid crystals, which were deposited on standing. His family physician confirmed the existence of gout, and agreed with me that the main treatment must be dietetic. After consultation with his family, it was decided to send him to Carlsbad, and he went, carrying a letter to Dr. Kraus, under whose care I placed him. He went through a carefully regulated course of treatment by the waters, with strict attention to his diet, by which his general health was very much improved, but there was no improvement in his vision. On his return I made a careful examination of the fundus of each eye, but could discover no appreciable change in the condition of the blood-vessels or the retina. While there was no demonstrable increase in the number or size of the patches of exudation, there was certainly no improvement. Peripheral vision was still fairly good, but he could not read at all with the left eye, and only with great difficulty with the right. This patient is still living, and the eyes show no perceptible change.

CASE II.—Early in March, 1890, I was consulted by a lady, aged forty-five years, whose vision had been failing for some months and who had never worn glasses. In November of the previous year she had suffered from an attack of *la grippe*, which assumed the form of asthma and bronchitis. She soon recovered from this attack, but suffered from a relapse, which was accompanied by severe neuralgia of the left side of the face and in the teeth on the left side, and by marked oedema of both lids. She had long suffered from gouty symptoms and was saturated with the disease, the chief symptoms being an obstinate general eczema and renal colic. She had one living child and had had four miscarriages. Syphilis could be absolutely excluded. She had been to Aix-les-Bains on several occasions and had always been greatly benefited by the waters. When I saw her there was marked oedema of the left upper lid and orbital tissue, but no other external evidence of trouble. There was compound hypermetropic astigmatism in both eyes, the right eye being the more defective, and with the refractive error corrected vision was $\frac{2}{3}$ — in each eye. She could read Jaeger 5 with sph. + D. 2.50 cyl. + D. 1.50, axis 180°, but could not read any smaller type. The cornea, anterior chamber, and iris were normal. There were peripheral opacities in both lenses, most marked downward and inward. There was an irregular central color scotoma in each eye, but no limitation of the field for form. The muscles were normal in their relations for all distances.

The fundus showed the following conditions: The optic discs were reddened and their outline was decidedly blurred as if smeared with a yellowish exudation. Both arteries and veins were reduced in the caliber of their lumen, and the white lines along the vessels were very broad and extended well toward the peripheral branches, particularly in the arteries. At the posterior pole were a series of patches of exudation of varying size and shape grouped irregularly around the macula, most of them being in the inner layers of the retina. There were no hemorrhages in the retina in either eye. The heart was quite feeble and irregular in action and there was a faint mitral regurgitant murmur. She had never suffered from an acute inflammatory attack of gout.

Repeated and very careful quantitative and qualitative analyses of the urine were made, the whole quantity passed in the twenty-four hours being examined, and this never exceeded fourteen or fifteen ounces. Its specific gravity varied between 1.020 and 1.028, its reaction was decidedly acid, and it was always dark-colored and turbid, and on standing cast a bulky precipitate. It always contained a small quantity of albumin, but no sugar or casts were ever found. The precipitate was made up almost entirely of uric and phosphatic acid crystals.

The patient was immediately placed upon the following dietary: For breakfast, weak black tea with a very little milk and no sugar, eggs scrambled or soft-boiled, a small portion of fresh fish, and occasionally an orange or some grapes. Dinner in the middle of the day: fish, poultry or game, underdone beef or mutton twice a week, fresh boiled green vegetables, toast or Graham bread, no butter; no starches, sweets, pastry, or ice-cream; no wine. A glass of lithia water with an effervescent lithia tablet at each meal. Under this dietary her general condition materially improved, and in the latter part of June she went to Carlsbad and placed herself under the care of Dr. Kraus. Under his carefully regulated treatment, both as to diet, baths, and drinking the spring waters, her improvement was very marked, not only in her general health, but also in her vision, so that when I saw her in October, 1890, her vision was $\frac{2}{3}$ — in the right eye, $\frac{2}{3}$ + in the left eye, and she could read Jaeger No. 1 with ease, with the refractive error corrected. The fundus, however, did not show much change. The white lines along the vessels were as distinct as ever and seemed to have extended still farther toward the periphery. There was no occlusion of the arterial lumen, however, at any spot. Some of the patches of exudation seemed to have shriveled or contracted in size, and there were apparently no new spots of exudation. The scotomata in the field were smaller in diameter.

The patient has rigidly maintained the dietary laid down for her and her general health is very satisfactory. An ophthalmoscopic examination is made at intervals of several months, but no material change has been noticed, so that it seems fair to assume that the disease process in the eyes has thus far been stayed.

CASE III.—In April, 1891, I was sent for to see a lady from the West who had suffered from inflammatory gout for many years, and was so crippled by the disease that she moved with great difficulty. She was sixty-eight years of age, and for some months had been conscious of a failure of vision in reading, and very recently for all objects at any distance. She had noticed that her eccentric vision was better than her central vision. The media were clear and the iris normal. R. E. V. = $\frac{2}{3}$, unimproved; L. E. V. = $\frac{2}{60}$, unimproved. There was a hypermetropia of one dioptré, and with sph. + D. 5 she could still read Jaeger No. 6 with the right eye. With the left eye she could read nothing smaller than Jaeger No. 14. The tension was normal. There was no limitation of the field for form in the right eye, but there was an ill-defined central scotoma for color. In the left eye there was an irregular scotoma both for form and color. The ophthalmoscopic examination showed in the right eye well-marked white lines along the arteries and veins, extending well beyond the margin of the disc, and one small patch of yellowish exudation in the retina just above the macula. In the left eye the symptoms were much more marked. The caliber of both veins and arteries was decidedly reduced, and the white lines along the vessels were very broad. There were numerous patches of exudation in the retina, round and oval, and both superficial and deep, grouped round the disc and macula, but there were no hemorrhages. In two of the smaller arterial branches the lumen seemed entirely obstructed. This

patient passed about thirty-two ounces of urine in the twenty-four hours, having a faint brown color and acid reaction, with a specific gravity of 1.022, and a rather copious deep-yellow sediment was deposited after standing a few hours. It contained no albumin, no sugar, and no casts, after repeated examination. The deposit consisted of uric-acid crystals and urates. She stated that her father and several other members of her family had suffered from a similar loss of vision after they had passed middle life, and that they were all gouty. This patient was under my constant care for more than a year, and is still seen at intervals. At no time have there ever been any symptoms, either objective or subjective, of renal disease.

After a careful study of this case, it seemed almost hopeless to expect any benefit from regulating the diet, owing to her age and the advanced stage of the general malady, and I contented myself with prescribing a general tonic regimen, including small doses of whisky and free lithium carbonate dissolved in lithia water. The changes in the blood-vessels and the retina slowly advanced, the white lines creeping toward the periphery and the patches of exudation increasing gradually in size and number. On two occasions small hemorrhages occurred on the disc margin of the right eye, apparently capillary in origin. In October, 1892, she had a slight cerebral hemorrhage, causing temporary impairment of speech and transient numbness in the right arm and leg, from which she entirely recovered, and there has been no recurrence of these symptoms. She is still very helpless and can only move about with great difficulty and with constant assistance. The heart's action is feeble, but fairly regular. The condition of the urine has somewhat improved. She passes about the same amount, but it has a lower specific gravity and there is less sedimentary deposit.

CASE IV.—In April, 1891, I saw a man, aged forty years, who gave the following history: He had always had somewhat imperfect vision in both eyes, owing to the scars of old corneal ulcers dating from childhood. He had been at various times a sailor, miner, ranchman, and barkeeper, and had always "lived high" when his means allowed it. For some months the vision in the left eye had grown much worse, so that he was only able to read the largest type. When I saw him I found the following conditions: There were faint opacities in the cornea of each eye, that in the right eye being central. R. E. V. = $\frac{3}{800}$, unimproved; L. E. V. = $\frac{2}{800}$ +, unimproved. With the exception of the cornea, the media were clear. He could read Jaeger 3 with the right eye with sph. + D. 1.50, but he could only read the heading of a newspaper with the left eye. There was no scotoma for form, but there was an irregular color scotoma in each eye. The ophthalmoscope showed in the right eye one small hemorrhage on the margin of the disc, but none in the left eye. In both eyes the white lines along the arteries were quite marked, particularly in the left eye, where they were also evident along the veins, and the lumen of both sets of vessels was narrowed, not only on the disc, but in the left eye for some distance beyond it. The outlines of the discs were blurred or smudged, and the discs themselves much reddened. There were no patches of exudation in the right eye, but in the left eye there were a number of irregular yellowish patches above and to the nasal side of the macula—all apparently in the inner layers of the retina—and one patch on the temporal margin of the disc. The heart was irregular in action, but otherwise apparently normal. The urine contained albumin, but no sugar or casts. There were about thirty ounces passed in twenty-four hours, which was acid, had a specific gravity of 1.026, and deposited a thick, brown precipitate, consisting mainly of uric acid and urates. The man denied syphilis, and had no trace of any specific lesion. There was a mild eczema on his hands and feet, and some chalky deposits in the middle and third fin-

gers of both hands. He had drunk all sorts of wines and liquors for many years, but he had never used tobacco because it nauseated him.

The man was very stout and his breathing was very short, and after any exertion he would have attacks of mild dyspnea. The patient's diet was at once regulated, and his daily supply of alcohol was reduced to the lowest amount of whisky. He was put on a general tonic treatment, with digitalis and small doses of potassium iodide, and he was advised to drink lithia water freely. Under this treatment his general condition began to improve, but its progress was slow, while the condition of the eyes grew steadily worse. The scotoma increased in size, the central vision deteriorated, the outlines of the discs became absolutely lost, though there was no swelling and no rupture of retinal blood-vessels. During the first month of treatment, subconjunctival ecchymosis occurred in both eyes, and this recurred several times during the following four months. The patches of exudation increased in number and size in the left eye, and new ones appeared in the right eye—all grouped around the macula or in the vicinity of the optic disc. The degeneration in the walls of the blood-vessels became more and more marked. The white lines broadened and extended farther toward the periphery, the deposit being more marked in the arteries than in the veins. The lumen of both arteries and veins became narrower, and toward the end there were several small arterial branches which were apparently entirely occluded. In both eyes there developed in several places fusiform aneurysmal dilations of the arteries, and on the distal side of these dilations the artery was always markedly reduced in caliber. The white lines were always broader and more marked at the points of bifurcation of the vessels.

In the latter part of September the patient developed pneumonia on the right side, and while ill with this pulmonary complication had a cerebral hemorrhage, which produced partial left hemiplegia, though his speech was but little affected. He did not rally from the pneumonia, and died on the sixth day, apparently from heart failure. I was fortunately enabled to make an autopsy, and removed the posterior halves of the eyes and optic nerves as far as the chiasm for examination. The autopsy showed very extensive degeneration of all the intracranial vessels, both arteries and veins. The circle of Willis was very stiff and rigid. The larger arteries retained some elasticity, but the smaller vessels were very stiff and in places had apparently lost all power of contractility. There was a small clot in the right anterior lobe, near the lower margin of the paracentral lobule, and another one in the right corpus striatum, near the supero-anterior region. The microscopical examination of the retina, optic nerve, and chorioid proved very interesting and absolutely confirmed the ophthalmoscopic diagnosis. All of the sections of the optic nerve, retina, and chorioid showed the signs of widespread arterio-sclerosis and phlebo-sclerosis. The adventitia and media were decidedly thickened, but in most of the sections the main increase was in the intima, which in many places was so marked as to almost obliterate the lumen. This was particularly noticeable in vessels at some distance from the margin of the disc. The proliferation in the adventitia was largely granular, while the thickening in the intima was mainly due to hyaline proliferation. Numerous fusiform aneurysmal dilations were found in the arteries, almost always at the point of origin of a branch, and on the distal side of these dilations the caliber of the vessels was markedly narrowed. No extravasations of blood were found, except one small one in the right eye near the disc, and previously noted with the ophthalmoscope. The nerve fibers on the papilla and in the retina were markedly varicose and separated by spaces filled with finely granular matter. The connective-tissue fibers were but little

altered. In the retina there was a decided thickening of the nerve-fiber layer, due to infiltration between the fibers of a mass of fine granules, aggregated in heaps, with occasional distinct cells provided with a cell wall and filled with the same granular contents. These aggregated masses of fine granules and cells extended through all the layers of the retina except the external layer. The capillaries on the optic disc were greatly dilated and accounted for the hyperemic condition seen with the ophthalmoscope, but between the capillaries were patches of fine granules similar to those in the retina. Sections of the optic nerves as far back as the chiasm showed the same changes in the walls of the blood-vessels as existed in the retina, but there were no special changes in the nerve fibers back of the eyeball and the nerves could be regarded as healthy.

In the chorioid the blood-vessels showed the same changes. The adventitia and intima of the arteries were thickened, the proliferation being more marked in the adventitia. The veins also showed the presence of phlebo-sclerosis. No very marked pigmentary changes were found, though there was some slight atrophy of the hexagonal cells. No exudation of any kind was found in the chorioid, except in the thickened coats of the blood-vessels.

CASE V.—In October, 1891, I saw a lady, aged sixty-five years, who for some months had noticed a gradually increasing blur before the right eye, and recently the same indistinctness of vision had appeared before the left eye. The media were perfectly clear, and the external aspect of the eyes was normal. R. E. V. = $\frac{2}{3}$ +; L. E. V. = $\frac{3}{8}$ —, unimproved. The ophthalmometer showed a hypermetropic astigmatism of one dioptre; axis, 90°. She could read Jaeger 5 with sph. +D. 3 with either eye. The tension was normal, and there was no scotoma or other limitation of the field. The ophthalmoscope showed an interesting picture. The optic discs were very red, but not swollen, and the outlines completely blotted out, though edema was scarcely perceptible. The appearances resembled those of papillitis without the swelling, and were more marked in the right eye. The vessels, both arteries and veins, showed the white lines well marked almost to the equatorial region of the eye, the deposit in the adventitia being, however, very irregular. In places there seemed to be a fusiform aneurysmal dilatation in both arteries and veins, the lumen of the vessel on the distal side of these swellings being nearly obliterated. This change was more marked in the arteries than in the veins. At the first examination no spots of exudation were discovered, but, as time passed and her vision grew worse, patches of exudation in the retina began to make their appearance around the macula and between the latter and the papilla.

This patient had always been gouty, and for some years had maintained more or less carefully an anti-gout dietary. The heart's action was feeble and irregular, but no organic lesion was made out. There were about twenty-six ounces of urine excreted in the twenty-four hours, which was dark-yellow in color, acid, and deposited a copious brown precipitate. There was a small amount of albumin, but there were no casts and no sugar. The precipitate consisted mainly of uric acid and the urates, with some phosphatic crystals. It was very interesting to note the gradual development of the patches of exudation in the retina, and the very slow extension of the disease of the vascular walls. The very marked development of this lesion in the retinal vessels, together with the condition of the urine and the gouty history of the patient, pointed to extensive disorganization of the vascular walls throughout the body, and to a probable rupture of some one of the cerebral vessels at no distant day. The vision slowly grew worse, so that eight months after my first examination she could no longer see to read even the largest type with either eye. Under dietetic management

and the free use of lithia, the condition of the urine improved very much, but the uric acid never entirely disappeared. Thirteen months after her first visit she was, without warning, attacked by all the symptoms of an "apoplexie foudroyante," and died in three hours without regaining consciousness.

I was permitted to make an autopsy and to remove the posterior halves of the eyes for microscopic examination. On taking off the skull-cap, the venous congestion of the dura mater and pia mater was very marked. All the arteries of the brain were found extensively diseased. In the substance of the left frontal lobe, about half way between the middle and inferior frontal convolutions, and dipping backward toward the fissure of Rolando, was a very extensive clot, as large as an olive, and in the paracental lobule, near the median line, was another extravasation, not so thick, but extending for nearly an inch in every direction, breaking down the brain substance completely. The middle and anterior cerebral arteries were in spots almost completely rigid, and the walls very thick and brittle. The same condition existed to a marked degree in all the arteries at the base of the brain. There was another small clot in the pons, near its under surface and far back, about as large as a split pea.

The optic chiasm, optic nerves, and posterior halves of the eyeballs were carefully removed and hardened for future examination. In making the sections from the nerves, my attention was directed principally to the condition of the blood-vessels, and in all of the sections, both of the nerve, retina, and chorioid, there were evidences of extensive arterio-sclerosis and phlebo-sclerosis, resembling closely the lesions described by Thoma. The adventitia and media were enormously thickened by hyaline and atheromatous infiltration, and the intima was in many places so increased in diameter as to project into and narrow the lumen of the vessel, particularly at the points of origin of small vessels. In two places in the retina there was found complete obliteration of one of the smaller arterial branches by the thickened intima, and one section showed a similar obliteration of the lumen of one of the smaller veins. The change in the coats of the blood-vessels was relatively as marked near the equatorial region of the retina as it was near the papilla. In most of the arteries the thickened adventitia was accompanied by a corresponding thickening of the intima, but in the veins this proportionate relation did not seem to hold good, the changes in the outer wall being here more marked.

As regards the nerve fibers on the disc and in the retina, they were here and there separated by oval spaces, which were sometimes empty and sometimes contained a mass of fine granules. There was in places slight varicosity of the fibers, and in the retina there was a decided thickening of the nerve-fiber layer, and to a less degree of the connective-tissue elements. Those sections which included patches of exudation showed marked thickening of the nerve-fiber layer, the thickening being due to a mass of granular bodies, some being distinctly provided with a cell wall and nucleus, while others seemed mere aggregations of granular matter. Within the limits of these patches of exudation the nerve fibers showed many varicosities. The same variety of granular exudation or degeneration was found in all the deeper layers, except that of the rods and cones, but to a much smaller extent. The exudation was largely confined to the nerve-fiber layer, and in several instances the spaces between the nerve-fibers seemed absolutely empty. There were no hemorrhages found in any of the sections. The region of the margin of the disc showed marked changes in the capillaries, which were generally dilated though their walls were thickened. This condition existed all over the disc and accounted for the extreme red appearance seen with the ophthalmoscope.

The blood-vessels of the chorioid showed similar lesions to those found in the retina. The adventitia and intima of the arteries were thickened, the adventitia showing the greater change. In a few sections the veins also showed a distinct thickening of their coats. The layer of hexagonal pigment cells showed patches of atrophy in some places. There were no patches of exudation found in any of the sections, and though spaces were found between the connective-tissue framework, which sometimes contained a few granular masses of small size, they did not differ materially from the ordinary chronic signs of senile degeneration of the chorioid. There was no conspicuous pigmentary change found in any of the sections.

Sections made from the optic nerve back of the eyeball showed the same marked changes in the central artery of the retina, mainly in the adventitia. There was little or no change in the aspect of the nerve fibers in this part of the optic nerve from that which is met with in a state of health.

In conclusion, the points to which I wish to draw attention are as follows:

1. The changes in the fundus are always bilateral, though rarely symmetrical in the two eyes.
2. The degeneration in the walls of the blood-vessels and in the retina cause marked impairment of central vision, little or no loss of peripheral vision, and never end in blindness.
3. The loss of central vision is always progressive up to a certain point, unless the cause of the lesion is recognized early in the onset and immediately and properly handled. Improvement in the vision after the disease is established can not be expected.
4. Hemorrhages into the retina are rare except in the early stage of the disease. Their absence later is probably due to the fact that the strength of the vascular walls is increased by the deposit, though their elasticity is diminished.
5. The most marked feature in the fundus is the development of arterio-sclerosis and phlebo-sclerosis. This is seen by the ophthalmoscope in the vessels of the retina, and the microscope shows that the degeneration exists as well in the vessels of the chorioid and optic nerve.
6. Another almost equally pathognomonic symptom is the peculiar yellowish granular exudation in the retina, located by the ophthalmoscope around the posterior pole of the eye and generally leaving the macula intact, and proved by the microscope to be mainly in the nerve-fiber layer, though found in all the layers except that of the rods and cones.
7. The changes in the optic-nerve fibers seem to be almost entirely intra-ocular, and can not be traced for any great distance back of the eyeball.

REASONS FOR THE REMOVAL OF ABDOMINAL TUMORS.

By F. BYRON ROBINSON, B. S., M. D.,

CHICAGO.

PROFESSOR OF GYNECOLOGY IN THE CHICAGO POST-GRADUATE SCHOOL;
GYNECOLOGIST TO THE WOMAN'S HOSPITAL, CHARITY HOSPITAL,
POST-GRADUATE HOSPITAL, AND COLUMBIA HOSPITAL.

(Concluded from page 143.)

ABDOMINAL tumors should be removed on account of the danger of axial rotation. The literature which takes note of a tumor rotating on its axis covers only about

thirty years. Rokitsansky, of Vienna, was among the first to call attention to the subject. The writer estimates from literature and observation that about eight per cent. of ovarian and parovarian tumors rotate on their axis. In 1891 Mr. Tait told the writer that he had, up to that date, sixty-two cases of rotated tumors. While a pupil of Mr. Tait for six months the writer saw four tumors rotated on their axes. Almost any abdominal or pelvic tumor may rotate on its axis. The writer has observed in an autopsy rotation of the cæcum and ileum on each other three quarters of a turn, but insufficient to obstruct the fecal current. Volvulus is only axial rotation of abdominal viscera. In the intestinal tract volvulus occurs sixty per cent. in the sigmoid flexure, thirty per cent. at the cæcum, and ten per cent. in the small intestine. Axial rotation of the digestive tract constitutes about four per cent. of all intestinal obstruction. It is no doubt due to a fatless elongated mesentery and previous constipation. As regards the causes of axial rotation of abdominal tumors, the writer is convinced that it is due to visceral rhythm. Any viscus which possesses an elongated attachment may rotate more or less on its axis. The uterus has been found rotated so as to demand operation. The kidney can, and does, rotate on its axis, resulting in partial or complete obstruction—the obstruction of its ureter causing hydronephrosis, and the obstruction of the renal vein due to twisting interferes with circulation and nourishment. It is possible for the spleen, in certain abnormal conditions, to rotate on its axis. Axial rotation of abdominal tumors may be partial or complete. It may be acute or chronic. An acute case generally acts in the following manner: A woman has an abdominal tumor. She has a sudden onset of pain; she will perhaps vomit. In twenty-four to forty-eight hours the abdomen will gradually enlarge. If it enlarges very extensively, the patient becomes pale and faint. The enlargement is the result of (a) the obstruction of the return venous flow from the tightness of the twist in the pedicle; (b) the dilatation of the veins in the tumor; and (c) the rupture of a vein in the tumor. The rigid-walled artery is difficult to occlude, and so keeps pumping its stream of blood into the tumor. The soft-walled, easily compressible vein is quickly occluded by the twist in the pedicle, and so all, or nearly all, the blood pumped in by the artery is retained in the tumor. The consequence is a sudden abdominal enlargement. Of course a woman may bleed to death in her own tumor, and such cases are on record, confirmed by autopsy. The tumor may twist so much on its pedicle that it may occlude both vein and artery. It may rotate so vigorously that it will be entirely twisted off or severed from its connections. In such cases the tumor acquires nourishment from the surrounding viscera. The trauma resulting from the axial rotation induces sufficient irritation to produce an exudate on the surface of the tumor. This exudate undergoes organization, acquiring blood-vessels, nerves, and lymphatics sufficient to nourish the tumor without its old pedicle. The writer saw with Mr. Tait one tumor sufficiently rotated on its pedicle to occlude the vein and artery, which was nourished by innumerable delicate, newly-organized processes of tissue spread over the circumference of

the tumor, and attaching itself to the adjacent viscera. In my own practice, while performing laparotomy, I have been surprised to find a dermoid ovarian tumor the size of a coconut entirely without a pedicle. It was wholly nourished by omental adhesions. The patient gave me a history of a severe attack four years previous from which pain and tenderness continuously clung to her. My first attention to axial rotation of tumors was in 1884 at Heidelberg in the clinic of Professor Czerny. One day a middle-aged lady suddenly appeared in the clinic who had come from her home in the country very sick. Professor Czerny put her on the table and examined her carefully. She had a high pulse and temperature and a dusky countenance. She appeared very ill. Professor Czerny said: "Gentlemen, I can not make the diagnosis. I will examine her again and perhaps operate to-morrow." The writer anxiously waited until the next day, when, sure enough, the woman was put to sleep on the operating-table. On opening the abdomen, a tumor of the size of a melon appeared in the wound. It was dark red in color, and Professor Czerny pronounced it gangrenous. It was easily removed and its pedicle ligated. That was a cyst rotated on its axis, and besides, it was not gangrenous, as such tumors rarely become gangrenous in the abdomen, and if washed well will show the color of normal tissue. Gangrene generally comes from tapping such cysts or the digestive tract may infect them. Cases have been frequently recorded where death followed tapping. Air entered the cyst and infection resulted. Axial rotation of abdominal and pelvic tumors may pursue a chronic or slow course. In such a tumor diagnosis is very difficult. The pain in such cases will be almost wholly carried by the sympathetic nerve, and the pain due to irritation of the sympathetic is generally a dull, heavy ache. It is a dragging pain. Cerebro-spinal nerves induce sharp, lancinating pain. So that slow axial rotation of abdominal tumors will be accompanied by dull, heavy, dragging pain. It may be noted that whenever there is more than one tumor in the abdomen the chances are very much increased for axial rotation. Pregnancy enhances axial rotation much more than the presence of a double tumor, because the uterus empties itself suddenly, and just after labor the tumor is apt to rotate. The writer has seen Mr. Tait operate on a woman six weeks after delivery for an abdominal tumor which had rotated about three times and a half on its pedicle. She was quite ill from delivery until after the operation, when she rapidly recovered. The strikingly easy manner in which operators speak of gangrenous tumors in the abdomen with recovery calls for objections. Recovery after gangrene or local death in the abdomen is extremely rare. What is usually called gangrene is simply dark tissue filled with venous blood. Now, if this dark tissue is removed and well washed the gangrenous idea will be displaced by the frequent appearance of the idea of normal white tissue. Air must in some way get to a tumor to admit of gangrene, and air enters by (a) tapping, (b) digestive tract, (c) genito-urinary tract. If a cyst has rotated sufficient to twist off its pedicle and become nourished by adhesions to adjacent viscera, it is more dangerous than the original tumor on account of its fixation and adhesions. It is generally more

liable to infection from the natural channels from its more extensive vascular connection. A tumor should be removed from its liability to axial rotation. A tumor rotated on its axis is dangerous to a patient from (a) hæmorrhage into the cyst; (b) gangrene; (c) because it may unduly enlarge from filling the veins of the tumor; (d) it may become fixed by adhesions and thus endanger the viscera; a fixed tumor is more dangerous than a movable one; (e) it may become infected and suppurate; (f) chronic axial rotation may exhaust a patient by pain; (g) it may result in trauma to viscera or perforation of viscera by pressure.

Abdominal tumors should be removed on account of the danger of rupture. It is a fact, which the writer has definitely observed, that tumors (ovarian and parovarian) will repeatedly rupture and fill in the living woman. In one case under my care the parovarian cysts repeatedly ruptured and filled during a year's personal observation. At the time of rupture the young woman of twenty-four would experience a sense of relief. The abdomen would become flattened and during the few succeeding days she would urinate frequently and profusely. Three years previously the writer had demonstrated that if a dog's peritoneal cavity was filled with water he would urinate profusely for two or three days. In removing ovarian tumors the writer has found old scars where such cysts had ruptured and refilled. The rupture may be due to violence or the continued pressure on some point of the tumor, thinning its walls so that leakage occurs. A rupture of non-infected cyst does no harm to a woman; but when a cyst containing infected material ruptures in the abdominal cavity death is almost inevitable. Hence such tumors which menace life should be removed on discovery. Cystic abdominal tumors are apt to rupture from increase of abdominal pressure, which, being continued long on single points of a cyst, either thin its walls so they will leak, or rupture by any violence. In one case the writer removed an ovarian tumor which gave a distinct history of rupture one year previous. A distinct scar was found about the size of a fifty-cent piece on the cyst to tell the story of rupture. Abdominal tumors may endanger life by rupturing into hollow viscera, as the gut, bladder, or vagina. From such rupture infection is almost sure to follow. The worst infection follows rupture in the digestive tract and second into the bladder. The writer has removed ovarian tumors with success which had ruptured into the digestive tract and almost destroyed the patient by chronic suppuration and exhaustion. About the worst of such tumors are ovarian dermoids which rupture into the sigmoid or rectum, for they make such dangerous adhesions. Two cysts may press so hard and long against each other that the walls in contact will fuse and the rupture will occur in the fused septum, which complicates by more adhesions and size of tumor.

The pressure occasioned by abdominal tumors demands their removal. A tumor pressing for a long time against a gut wall may thin it so that germs or their products may pass into the tumor and the tumor becomes infected; inflammation follows and may be accompanied by suppuration. But pressure must be observed to take place in two

directions—viz., toward the tumor and toward the viscus. The damage from pressure in abdominal tumors is threefold: (a) The effect of pressure on viscera; (b) the effect of pressure on the tumor; and (c) the effect of the pressure on the function of viscera, both remote and distant. This last idea was discussed under reflex action. It was shown how abdominal tumors induced hydronephrosis by partial or complete occlusion of the ureters. Tumor pressure will even induce interstitial and parenchymatous nephritis. Three fourths of women long possessing abdominal tumors have kidney disease. The tumor may press on some segment of the digestive tract and induce obstruction of the fecal current either mechanically or by reflex paralysis. The main point of pressure is on some fixed portion of the gut, the rectum, sigmoid, or colon. The canals, ureter, or gut curiously maintain their patency for a long time on account of their continual dilatation and contraction. The writer has seen these canals entirely surrounded by dense tissue of tumors, but a distinct tunnel still existed through the tumor considerably larger than the empty collapsed canal. Abdominal tumors, in a word, by pressure induce obstruction mechanically or by reflex irritation (spasm or paralysis), and should be removed. The continued pressure gives rise to (a) inflammation, by allowing infection to travel; (b) the inflammation may go on to supuration and end in perforation, internally or externally. The effect of pressure is very apparent on circulation—on vascularity. The pressure acts mainly on, or the effect is most evident on, the great venous plexuses. The hemorrhoidal from the inferior mesenteric suffers the most, as most of such patients have hemorrhoids. The effect of the pressure is also plain on the plexus pampiniformis, on the vaginal plexus, and on the venous bulb of the vulva. Areas of tissue become œdematous. The limbs swell. The pelvic organs suffer the main brunt from the mechanical pressure, while the distant organs suffer the reflex action the most evident. The mechanical pressure effect on circulation is (a) congestion, (b) œdema, (c) dilatation of veins (hemorrhoids). It must not be forgotten that since the sympathetic is mainly distributed to blood-vessels the reflexes from pressure on the vessels are effective and profound, local and general.

The writer has noted the effect of tumors on the color of the skin for a long time. It has long been recognized that the main source of pigmentation arises from the spleen. Jaschowitz started the view that the spleen was the source of pigmentation by dividing the sympathetic plexus going to the spleen on the spiral splenic artery. This experiment enhanced pigmentation. No doubt the liver is a second source of pigment from the fact that it buries red corpuscles, and pigmentation is very noticeable in malaria which profoundly affects the liver (and spleen also). But still the spleen may be credited with the main origin of pigmentation. The writer has noted about all colors of pigmentation (brown, black, and yellow) in such women, especially in a woman who has had a tumor a long time. The author saw a woman last month who had had a tumor for sixteen years, whose color was a deep brown and yellow, with patches of atrophied, glistening skin in-

terspersed. The tumor disturbs the rhythm of the spleen. The spleen is capable of a rhythm by (a) its elastic covering of peritonæum, (b) its elastic capsule, (c) its cells have the power of enlarging by receiving excessive blood. When the tumor irritates the splenic plexus it destroys its rhythm, and hence its nourishment. The nourishment being disturbed, its products—pigment—will be disturbed. Irritation induces the spleen to produce excess of pigment. The parts of the body most intensely pigmented are those exposed to the air. Yet the pigmentation is general. The simplest example of pigmentation is observed in pregnancy, which is generally localized to the genitals, breast, and linea alba.

But abdominal tumors create more definite and general pigmentation. The pigmentation is effected by the irritation passing to the abdominal brain, where it is reorganized and emitted to the spleen.

The irregular forces coming at irregular times to the spleen derange its rhythm, and consequently its nourishment. Pigmentation is the result of a silent process accomplished by reflex irritation and shows general derangement of the visceral economy. It is merely the surface tale of profound processes, indicating the removal of the offending invader. It is difficult to convince physicians that a laparotomy is really demanded to remove adhesions. Adhesive bands have blood-vessels, lymphatics, and nerves.

A tumor should be removed from its danger to create adhesions, but after they have formed they often require removal. They should be removed when they give rise to pain, when they distort and unbalance the viscera. They may occasion obstruction to any hollow viscus. They may strangle some viscus.

Even the lungs do not escape the evil influence of the presence of an abdominal tumor. The disturbance in the lung is mainly due to reflex irritation which disturbs the rhythm of the lungs.

Abdominal tumors should be removed from their liability to become infected.

The question may be asked, How does an abdominal tumor become infected or inflamed? Tumors frequently become infected, as is easily tested at the operation by observing adhesions—the result of infection.

The great highway by which abdominal tumors become infected is through the Fallopian tubes. Any laparotomist can easily see that inflammatory exudates arise at the fimbriated end of the tubes and from there spread. The infection travels by natural routes, especially along mucous channels. It particularly travels through the left Fallopian tube, as the writer has demonstrated that the lumen of the left tube is larger than that of the right.

The second great highway of infection of abdominal tumors is through the digestive tract. Germs or their products pass through the gut wall at pressure points and infect the tumor.

The third channel of infection is through the genito-urinary tract. A fourth is by tapping, allowing air to enter. The table presented with this article will show at a glance the reasons for removing abdominal tumors:

Heart.	<ol style="list-style-type: none"> 1. Irregular. 2. Hypertrophy. 3. Fatty degeneration.
Lungs.	<ol style="list-style-type: none"> 1. Disturbs rhythm—asthma. 2. Catarrh. <ul style="list-style-type: none"> (a) anæmic. (b) hyperæmic.
Liver.	<ol style="list-style-type: none"> 1. Disturbs rhythm. 2. Disturbs secretion. <ul style="list-style-type: none"> (a) Too much secretion. (b) Too little secretion. (c) Disproportionate secretion. 3. Pigmentation. 4. Nerve influence can check all secretion.
Kidney.	<ol style="list-style-type: none"> 1. Nerve impression can check all secretion. 2. Reflex irritation. <ul style="list-style-type: none"> (a) Too much secretion. (b) Too little secretion. (c) Disproportionate secretion. 3. Obstruction hydronephrosis. <ul style="list-style-type: none"> (a) Parenchymatous inflammation. (b) Intestinal inflammation. 4. Infection.
Digestive tract.	<ol style="list-style-type: none"> 1. Sensation. 2. Motion. 3. Secretion. <ul style="list-style-type: none"> (a) Too much secretion. (b) Too little secretion. THE EFFICIENCY OF NATURE'S REMEDIAL MEASURES.*

By EDWARD VON DÖNHOF, M. A., M. D.

WHEN I accepted an invitation to present to this body some views entertained by myself, in common, I doubt not, with a certain proportion of its members, with regard to

this subject, many of the great difficulties in the way of doing so in a thoroughly intelligible and acceptable manner, especially as regards the younger contingent of our members, did not occur to me. But, as I have earnestly endeavored to blend the *suaviter in modo* with the *fortiter in re*, and avoided as much as possible the semblance of dogmatism, it is hoped that the chiefest obstacle to a patient hearing on their part has been obviated.

In order to properly begin a presentation of our subject matter, it seems fitting to recall a few elementary definitions. First, What is disease? To simplify the answer, we may divide the phenomena recognized as evidencing disease into two classes—first, those indicating merely functional and temporary disturbances of the body; and, second, those indicating organic lesions and suggesting more or less persistent derangement of the bodily functions, based upon pathological changes of tissue.

As affording a diametrical contrast to functional or organic diseased conditions, we have the condition recognized as "physiological equipoise"—i. e., a status of the physical economy in which every function is regularly performed, and in which there exists no discernible or presumable organic lesion.

The next inquiry demands a definition of the relative attitudes of the condition of physiological equipoise to the phenomena of functional or organic disease. Medical philosophy adheres to the proposition that the tendency of all pathological phenomena—functional or organic—is to spontaneous disappearance; or rather to a disappearance as the result of either the increased vicarious functional activity of various organs of the body, or the combined increased activity of all the bodily functions. Given a condition of physiological equipoise at the period of invasion of the body by a diseaseing influence, it is presumable that a healthful condition will supervene, unless, indeed, the invading element be of so overwhelming a character as to bring about such rapid, baneful modification of physical functions as to necessitate fatal organic changes, which absolutely forbid the re-establishment of the physiological activity of the parts so changed. In this event, either chronic diseased conditions result, or *exitus*.

If the condition of the body be such, because of its general lassitude, even without specially marked functional disturbances, a cause of disease attacking it would find, as it were, a suitable soil for accentuating its presence. In such a state of affairs the automatic natural powers are at a disadvantage; but, even in the face of this truth, palpable and oftentimes thoroughly successful efforts to throw off the disease, and even bring about in a given individual an extraordinary condition of general health, result from the spontaneous activity of such residual functional strength as remained to the individual at the period of attack, and which was successfully fostered by the discreet attendant.

It is my purpose to emphasize as much as I may that all therapeutic measures which are of real avail in the management of all manner of clinical emergencies are and must of necessity be derived from an accurate observation of the play of natural forces. Hence it is of pre-eminent importance that a knowledge, or as much of it as is attain-

* Delivered before the New York County Medical Association, June 19, 1893.

able, of physiology, and the demands of physiological conditions, shall be brought to bear on the management of disease and the reconstruction of distorted anatomical conditions, and that the only safe or scientific method of procedure is based upon these requisites; and, *per contra*, that empirical therapeutic adjuvants are only logically admissible when they are distinctly suggested by our knowledge of physiological processes, and are measurably chosen in harmony with them. It would be an endless task to myself, and tax your patience too severely, to make of this paper an array of specific details with reference to the management of the sick and sore. I prefer, therefore, to limit myself to a weighing process of the portent of the more modern literature bearing upon this point, since, despite its high source and ostensibly authentic character, it appears to me to propound doctrines which either quite ignore the *vis medicatrix nature*, or virtually affect to counterpoise it. Foremost in the ranks of these *littérateurs* are those who consider the destruction of a handful of microbes by means of a germicidal therapeutics as not only necessary but all-sufficient in protecting the victim of disease or injury from threatened or impending dissolution. If I succeed in pointing the fact that, despite their dogmatic assertions w.l.n.g.h to the contrary, Nature retains for herself the maximum of power of final direction of the results of pathological processes, I shall have quite fully attained my purpose, and with it directed the current of a half-hour's thought on your part into propitious channels.

"No profound acquaintance with the history of science is needed to produce the conviction that the advancement of natural knowledge has been effected by the successive or concurrent efforts of men whose minds are characterized by tendencies so opposite that they are forced into conflict with one another. The one intellect is imaginative and synthetic; its chief aim is to arrive at a broad and coherent conception of the relations of phenomena; the other is positive, critical, analytic, and sets the highest value upon the exact determination and statement of the phenomena themselves.

"If the man of the critical school takes the pithy aphorism '*Melius autem est naturam secare quam abstrahere*' for his motto, the champion of free speculation may retort with another from the same hand, '*Citius enim emergit falsitate quam e confusione*,' and each adduce abundant historical proof that his method has contributed as much as that of his rival to the progress of knowledge. Every science has been indebted to bold, nay, even to wild hypothesis for the power of ordering and grasping the endless details of natural fact which they confer from the moral stimulus which arises from the desire to confirm or confute them; and last, but not least, for the suggestion of paths of fruitful inquiry which, without them, would never have been followed."

"From the days of Columbus and Kepler to those of Oken, Lamarck, and Boucher de Perthes, Saul, who, seeking his father's asses, found a kingdom, is the prototype of many a renowned discoverer, who has lighted upon verities while following illusions which, had they deluded lesser men, might possibly have been considered more or less asinine."

"On the other hand, there is no branch of science which does not owe at least an equal obligation to those cool heads which are not to be seduced into acceptance of symmetrical formulæ and bold generalizations for solid truths because of their brilliancy and grandeur; to the men who can not overlook those exceptions and insignificant residual phenomena which, when tracked to their causes, are so often the death of brilliant hypotheses; to the men, finally, who, by demonstrating the limits to human knowledge which are set by the very conditions of thought, have warned mankind against fruitless efforts to overstep those limits."*

Yet truths, as such, must often be accepted without being perfectly understood as to their origin, and the concomitant circumstances that gave rise to, and finally resulted in, their establishment as accepted expressions of fixed laws of Nature. Thus the mind with facility grasps the attitude of the observer who framed the proverb which is synonymous with the subject of this discourse, as having noted in every animate form an inalienable tendency to conserve its own existence and prosperity, even at the expense of that of weaker organisms, and that the rejoinder of the lad who, having had pointed out to him by his observant tutor the quick eye and dexterous movement of the crane as it darted its head into the water and caught a passing fish, "That is well enough for the crane; but how about the fish?" is but a homely epitome of the law of existence. So it is in the endless cycle of life: the stronger preys upon the weaker to the end and purpose of the survival of the fittest, and a common progression of the residuum toward a higher plane.

It is not the province of either philosophy or science to do other than rigidly interpret what they may of natural law as they find it, and to adapt their teachings solely, and freed from hypothetical chimera, to that law, never forgetting that coercion here portends only the *exitus* of reason.

It is distinctly the high prerogative of the physician to interpret with peculiar sincerity natural law, but it would seem that, despite the basic philosophy of his vocation, he is led, by desires which outstrip the pace of indisputable acquisition of knowledge, to indulge an ambition which, however commendable in itself, having ostensibly for its foundation the hope of lessening human suffering, too often launches the votary into turbulent seas of imperfectly analyzed data and irrelevant, though never so beautiful, kaleidoscopic speculations.

Nowhere else, as in the field of medicine—within the realm of what should be strictly philosophic teaching, and which does and should plume itself most acceptably when its precepts are based upon axiomatic premises—do there exist such emphasized and withal such insurmountable (?) contradictions in terms. And it does not appear that these fallacies become less obstinate because of the capacity and willingness, on the part of some who do not accept *ex cathedra* the assertions of their authors, to demonstrate such errors; and, *per contra*, offer the safest, being truthful and in keeping with the truth, substitutes for them.

* Huxley.

The chief difficulty, I take it, in the way of a natural solution of the errors which almost overshadow the handful of established truths upon which scientific therapeutics is based is to be found in the more or less fantastical embellishments with which modern teachers and writers are wont to garniture their labors with their disciples. The hot race for distinction and priority, and all the rest of the tinsel and particolored plumage of proclaimed eminence and pre-eminence, makes even of the should-be staid man of science an exuberant enthusiast; and hence dogmatic asseveration of half-fledged theories, which have grown out of purely impractical speculation, with the slightest semblance of or no foundation at all in experience, fill volumes upon volumes, each of which purports to be the "latest, best, and most undeniable treatise of any yet extant" upon any one of the host of topics with which the wise (?) men of our era employ themselves. The cheapness of reputation is unfortunately greater than in the day of the Roman philosopher and statesman who wished only that his "enemy would write a book."

To write a book in this our day is almost synonymous with creating one's self an authority (?), provided, indeed, that the writer does not differ too widely from the particular fad of a preceding one on the same subject, or does so diametrically, and supports his tenets with such an interminable array of arguments, whose matter is made to fit the occasion, that he compels the plaudits of that element in the profession of medicine identical in mental caliber with the mass of groundlings whose voices rend the air in appreciation of the loudest-mouthed stump orator.

The modest reticence which so charms the layman into profound respect for its possessor, as he contemplates the true votary of the healing art, is born of an inner conscientiousness which, were its true cause—paucity of real knowledge in the possession of the object of his admiration—known to him, would, perhaps, change this admiration into scoffing unbelief.

This characterization of the layman is not unlike the relative attitude of the wonder-dazed embryo medicus, who stares open-mouthed at his wisdom-enshrined (?) modern professor of bacteriology as he isolates with a precision all his own this, that, or the other coccus, and so interposes his skillful dexterity between the life and death of his charge. He, too, might scoff with better reason when he grasps the fact that the dogmatic dicta of his master are but the would-be-realized vaporizings of a dream, and it is at this point that ever-watchful sophistry and, worse, charlatany stand guard at the elbow of the false prophet, and overshadow with impenetrable mysticism the would-be-cunning vision of his inquisitor.

There was a time not long past when the "prentice boy" about to enter the laboratory of his master surgeon received parchments proposing to teach him the "art and mystery" of his calling. The art was small; the mystery great, profound, and overwhelming. His art, if true, consisted in crudely demonstrating certain oft-met experiences more or less well understood by himself, and proportionately well taught his fledglings. The mysteries consisted in cloaking the not well understood phenomena of disease and

injuries with draughts and plasters relatively harmless when the patient's residual strength was sufficient to protect him from their influence, and all potent for evil when no such good fortune befriended him—he died, despite the good offices of the master.

Harvey, the true father of modern physiology, opened what seemed to be the flood-gate of medical philosophy when he discovered the mechanism and office of the little trip-hammer force-pump—the heart—the whole economy subservient to its movements as it pushes on the flow of the red current of life, that conveys in its myriad cells the food to foster it, and in its waters a detergent for its noxious enemies. Much as we are disposed to foster with our admiration this great philosopher, as the impetus of modern research, we may not leave off as a part of correct history, as we gather from the study of the papyrus the fact that the Egyptian priests probably knew, as did Harvey, the functions of the heart, as well as those of the vascular systems directly and indirectly connected with it. It would seem that, having attained a certain height in the course of their inductive reasoning, they, as does the modern investigator, reached a point when their reasoning no longer served the purpose of their vaulting ambition to be all wise, and was promptly overshadowed by plausible hypothesis and its equally plausible fruit—empiricism. It may not truthfully be gainsaid that by means of now better understood and applied laws of physics and chemistry—among the most powerful products of which stand the modern implements of exact information—the store of curious but, for the nonce, measurably practically inapplicable facts has not been largely increased; nor can it be disputed that from this store there have been deducted some laws clearly tributary to the prevention of human ailment. Observe these narrowly; observe them in their wonderful simplicity, and it would seem that the human intellect that could not grasp with ease their portent and significance and picture with facile exertion the direful result of their absence or inactivity must be puerile indeed. Study them, however, as they appear hidden in the maze of sophistical "pros and cons" of the modern bookwriter—I had almost said scriptomania—and it does not tax the imagination severely to evoke again the phantom of a century since which taught the "arts and mysteries" of its calling.

Truth is of unique beauty, sublime in its simplicity, hallowed by its rarity; destined solely for good, it is readily grasped by him who seeks after it and would become its faithful purveyor and make it to bless the needy and teach the unadvised.

The tenets of modern writers who defend with an exclusive dogmatism the theory that all disease is due to an invasion of the physical economy by microbic hordes is neither in the particular that they promulgate such doctrines, nor in the character of their defense of it, new with them. Among the earliest writers similar views were entertained and defended in a similar fashion. Perhaps if the Dutch spectacle-maker Jansen, who by accident discovered the wonderful powers of a globe of glass which had fallen from a rod of that substance which he was melting, had not been born and had not thus given the initial

momentum to the construction of much of the paraphernalia of the modern laboratory and its myriads of instruments for exact (!) investigation, no one would be answerable now for the ponderous tomes announcing the era-revolutionizing truths (!) promulgated by the modern bibliomaniac and omniscient microbiologist.

Historic lore credits an ancient philosopher who, near the close of a long life, had in his own words "inflicted the eagerly suffering voluntary student of his works" with many tomes of his written thoughts and observations with this confession to one whom he loved next himself, and who thus importuned him: "O beloved master, whence did you glean this marvelous store of wisdom?" "By," he answered, "hoping incessantly that mine eyes saw aright, and that at some day in the future some one nearer the gods than myself may succeed in proving to be true a little of that which I have written. For myself, I am as yet conscious only that I know nothing."

From the very nature of the surroundings it would be inadmissible to conjecture that Koch, Pasteur, *et al.* have written with similar empirical foundation the teachings that set the world agog; and yet, if but the very essence of truth contained in their enunciations were isolated and arranged side by side with a front as impenetrable as that of a Roman phalanx, the phalanx would dwindle into contemptible insignificance before the pompous magnitude of the hypothetic possibilities deduced from these little gleaming sparks of not yet perfectly pondered truths. Yet the world would not willingly part with these; nor could it if it would; for truth is indestructible; but let the world use it stripped of dangerous confusing and with all plausible conjectures, the benefits growing out of them in their naked simplicity will sufficiently compensate.

When Lister, more than a score of years since, directed the attention of the medical profession to the necessity (!) of inveighing therapeutically against certain general influences which he considered responsible for most of the ill-success attendant upon surgical exploits, he at the same time promulgated his teachings with such zest and enthusiasm and measured the results obtained by him under the new order of things with an eye so exclusively alert to all manner of wondrous possibilities as growing out of the correct technique of his prescribed method, that the whole surgical world wondered, and a large part of it more or less blindly followed his lead.

I must not be understood as wishing in the least to detract from Sir Joseph's merited laurels, but those who patiently engaged in the same line of studies as led him to his conclusions, and observed closely the tide and portent of events as time progressed and experience accumulated, witnessed retraction after retraction of their erstwhile vehemently asseverated allegations on the part of the antiseptic school until they were forced, first, to yield the distinguishing title—antiseptic—which they had chosen, and next to confess the impossibility of preventing the invasion of wounds or the blood by mischievous micro-organisms by those very means which had but lately been adjudged infallible. Finally, when other and stronger detergents were brought into use, the great danger to life growing out of

their application to wounded surfaces in such strength as had been found necessary to destroy the vitality of the organisms more feared, necessitated a refuge to the simplest and most natural measures known, to which at this moment they concede all desirable efficiency—namely, hot water and chloride of sodium. Meanwhile, as experience grew apace under the new (!) régime, the necessity of an accurate technique with regard to the manner of making surgical wounds, to proper drainage, and to the prevention of even the least hæmorrhage after their closure, by suture or otherwise, emphasized itself. Now, add to these well-established principles—all in imitation of the spontaneous phenomena of Nature, occurring under provident circumstances—the rules of practice requiring the use of clean hands and mechanical implements, and the thorough cleansing of the surface which is to be the site of the surgical wound, and we have the sum total of what can be proved to be the sole foundation of surgical success, so far as human precaution can contribute to it. This is asepsis—the condition which Nature demands and which a state of physiological equipoise provides in the individual who has been wisely selected and properly prepared for a surgical ordeal.

In conclusion, it is not intended to stigmatize those who from sincere conviction adhere to the new doctrines and literally and apparently unquestioningly carry out its prescriptions. But every one may rightly claim the prerogative of demanding indisputable proof for the faith which he is asked to adopt. As for myself, I repudiate a doctrine which, as I understand it, affects to ignore in the spirit the necessity of subscribing to the axiom that, especially in medicine, "true science is the handmaid of Nature," and can only become an adjuvant to her when it is tributary to the increase of *natural* conservative power by natural means, where such is lacking. And, further, I submit that however efficient as germicides certain chemical agencies may prove to be in the laboratory, the same impracticability attends them in their adaptation to clinical issues, and renders the effect of their use here either nil or mischievous, as is the case with respect to the effect of many of the so-called chemical preparations, presumably prepared with the nicest precision as supplemental ingesta, intended for the correction of certain qualitatively defective conditions of the blood and tissues.

I submit that unless the inherent residual *vis resistentie naturalis* vouchsafes recovery, no man has yet attained the means of compelling such an issue artificially.

VASO-MOTOR DISTURBANCE.

REPORT OF A CASE.*

By E. R. AXTELL, M. D.,

DENVER, COL.

PROFESSOR OF HISTOLOGY AND BACTERIOLOGY, UNIVERSITY OF DENVER;
PATHOLOGIST TO ST. LUKE'S AND TO ST. ANTHONY'S HOSPITALS

VASO-MOTOR disturbance as a separate disease has no right to any claim of place. It is but a symptom, a symp-

* Read before the Colorado State Medical Society, June 21, 1893.

tom of importance and, with our present limited knowledge, a symptom demanding separate discussion.

By a vaso-motor disturbance we mean a disturbance of circulation due to perversion of the normal nervous influence over the blood canals.

The following case of intermittent general vaso-motor disturbance, with some permanent conditions, may help us to understand the known physiology of vaso-motor control:

J. C. A., aged twenty-eight, a machinist, married, was born in Illinois. In Colorado ten months. Family history excellent. Patient has always enjoyed good health. When a child, had mumps and measles. When seven years of age he had malaria for a period of six months. When he was eight years of age he fell down a cellar-way and struck on his head. Does not know whether he was rendered unconscious. From that time for several years his head felt feverish to him every night, and it was a habit of his to put his head against the cool wall of his bedroom.

From fifteen to twenty-three years of age the patient suffered with "dizzy, blind headaches." He had the attacks as often as from two or three times a month to two or three times a year. The attacks would start with frontal pain and nausea, and then he would have dizziness and a peculiar blindness, in which objects would be blurred and apparently jumping. The attacks would last about two hours, and then gradually go away, but the patient would feel depressed for several days.

Twelve years ago the patient had a mild typhoid fever. He was sick in bed two or three weeks.

Patient has been a great smoker since his ninth year. He also used chewing tobacco. Until recently he was accustomed to smoke from five to eleven cigars a day.

He denies alcoholism and syphilis. He has been married three years and has three children. His second child, a girl two years of age, suffers with a papilloma of the larynx, for which tracheotomy has had to be made.

The present trouble began in the fall of 1890. He noticed that, on getting into a heated room, peculiar sensations were felt all over the body and head, described by the patient as needles pricking the skin, which needles seemed to get hotter and hotter until, in from three to ten minutes, he began to perspire, when the paresthesia began to disappear. He says he does not perspire much, or at all readily, at any time. Before this trouble commenced he perspired just as any one would, and much more easily and freely than he does now.

With this trouble, or possibly antedating it a short time, he noticed that he was gradually drinking more water, and that he was annoyed by an increased desire to make water.

From this time this symptom has continued constantly, being always worse in cold weather.

Since the onset the patient has experienced the peculiar sensations in the skin only in winter, and that only on getting heated. The sensation seemed to start in the back, and almost instantly seemed to go over the entire body. When it was at its height the patient could not endure it. He would have to quit his work and go into a cool place.

The first winter the trouble was not so great, for the patient could overcome it by keeping on at his work until he began to perspire, when the trouble ceased.

The next winter the trouble did not bother him very much. He was able to work, and only a few times during the winter did he experience any trouble, and then only slightly.

This past winter the sensations started in early and markedly. He was keeping a grocery store early in the autumn, but,

because of his skin sensations and because of his desire to urinate so frequently, he gave up his work, and for three months he has not been able to do anything. During very cold weather he has to urinate from twenty to thirty times in the twenty-four hours. The patient states that he makes a good quantity of water each time, and that he can never hold it long without discomfort. Once or twice it has come involuntarily. As a rule, he does not have to get up at night to urinate.

Though the patient has avoided heated places during this winter, still he has had the peculiar sensations in the skin fully a thousand times during the season.

During the winter the patient has taken ten or fifteen Turkish baths. In taking the first bath it was fully fifteen minutes before he began to perspire freely. During this time he suffered intensely and moaned with pain. Since then he has had some trouble, but much less than with the first bath.

He states that frequently during the winter he has had to get out of bed because of this peculiar sensation. As soon as he gets cold he can again retire.

With this array of symptoms, the patient has a decline of mental vigor, feels languid, and is melancholic most of the time.

On careful consideration of his case, I found that he slept well, that he had no cough, that the appetite was fair. His bowels move two or three times a day, the stools being of usual consistence. Patient states that he drinks a great deal, but that he is always thirsty. He has a dry, burning sensation under the sternum almost constantly. Physically, the patient thinks himself in good condition. Present weight, 150 pounds. Since the onset of the patient's present trouble his sexual vigor has been less than formerly.

For several years, and antedating the present trouble, the patient has had indigestion. He complains of a dull, sore, tender feeling in the epigastrium, which is sometimes increased by taking food.

At times he has a dull, uneasy feeling in the right testicle and in the small of the back over the left kidney. At this place he has some constant tenderness.

During the past year the patient has had seven or eight boils on the back of his neck, some of which did not open but simply dried up.

The physical examination revealed the following rather negative condition: Pulse, 90; temperature, 98° F. Tongue dry and coated with yellowish fur.

Examination of lungs and heart showed nothing abnormal. No stone in the bladder on sounding.

Amount of urine excreted April 27th, 28th, and 29th, one gallon a day.

Examination of urine February 18, 1893: Urine of a light amber color, faint odor; specific gravity, 1.016; pronounced acid reaction; no albumin to heat or nitric acid; no sugar to Trommer's or Fehling's test.

The examination being continued, revealed that both pupils respond to light and accommodation. Fields normal for white except slightly contracted above. Eyes carried in all directions normally. Taste and smell normal. Hearing normal.

The examination of the eyes by Dr. John M. Foster revealed—

"Remote vision, $\frac{5}{6}$ in both eyes. Slight amount of hyperopia in right eye. No heterophoria. Amplitude of accommodation good. Ophthalmoscope shows a horizontal elongation of the left optic disc, which is not abnormal. Otherwise both fundi normal."

The patient presents no ataxia in the arm, leg, or chest muscles. Muscular power of legs and arms perfect. Dynamometer, R., 130; L., 125. Patellar reflex normal; no ankle

clonus. Cremasteric, abdominal, and epigastric reflexes present, but slow. Only strong stimulation will bring them out. Plantar reflexes normal. Deep reflexes of arms normal.

Tactile, localization, pain, muscular, and posture senses perfect throughout the body.

On the outer surface of both legs and feet the patient recognizes cold at once, but heat of considerable degree is poorly recognized and sometimes called "cool."

Examination of urine March 25, 1893: Amount passed, twelve ounces and a half. Patient had passed urine of nearly the same amount thirty-five minutes before. Urine very pale; specific gravity, 1.000; faintly acid; no albumin; no sugar.

In this patient we have, then, an array of symptoms due to disturbed vaso-motor control. The feverish head of the patient when a boy, after his head injury, is the first evidence of his trouble. The peculiar paresthesia and the increased urinary discharge are the later evidences. To fully understand the case under consideration it is necessary for us to review in a concise manner the known physiology of the vaso-motor system. We know that the nervous system controls the heart's action and regulates its force and frequency of beat; and we know that each artery and arteriole has its caliber increased and diminished by the nervous system. It is upon the muscular wall of the arteries and arterioles that the nervous system exercises its influence. This muscular coat in the smallest arteries is proportionately larger than it is in the larger arteries, and it is over these vessels that the nervous system especially exerts its control.

If we remove the blood-vessels of a rabbit's ear from the influence of the central nervous system by dividing its sympathetic nerve, the blood-vessels in the part dilate and remain so. Now, if the peripheral end of the divided nerve be stimulated, the dilated arteries return to their natural size, or become more contracted than normal.

The usual condition of an artery, a point midway between extreme dilatation and extreme contraction, is termed the normal *tone* of an artery. This normal tone is maintained by the nervous system, and every artery has a nerve which maintains in that artery the normal tone.

These nerves are called vaso-motor nerves, and we find them running from the spinal cord and sympathetic ganglia, now in the cerebro-spinal nerves and now in the sympathetic. There are evidently two sets of fibers in these nerves—one set of fibers producing, when stimulated, dilatation of arterioles; another set, when stimulated, producing contraction. These fibers are now called, respectively, vaso-dilators and vaso-constrictors.

The center for these fibers is now ascertained to be in the gray matter in the interior of the medulla oblongata. On each side of the median line, in or just beneath the floor of the fourth ventricle, we find this center. It extends from the calamus scriptorius to the level of the sixth nerve nucleus. Each division governs the vascular tone of its own side of the body, and lesions in its region may produce unilateral vaso-motor symptoms. From this center the vaso-motor fibers pass down the interior of the spinal cord, and issue from it along with the anterior roots of the spinal nerves. They then traverse the various prævertebral ganglia of the sympathetic system, and, accompanied by

branches from these ganglia, pass to their destination. The center in the medulla can be excited to reflex action by strong irritation locally applied, as by improper blood passing through the medulla. When the center is excited to reflex action, a general constriction or dilatation of the vessels of the entire body ensues.

From various experiments it seems probable that the general center in the medulla is made up of a number of individual or special centers, each of which governs the circulation of a definite part or organ. The vascular tone of the thoracic and abdominal viscera is especially thought to be regulated by a series of such centers. Tiny destructive lesions in portions of the medullary vaso-motor center have caused hæmorrhages to occur in the lungs, pleuræ, stomach, intestines, and kidneys.

Then, the well-known experiment of puncturing the medulla, producing glycosuria or polyuria by causing local hyperæmias of the liver or kidneys, confirms this view.

The vaso-motor center in the medulla is not the only center in the body, for secondary or subordinate centers exist in the spinal cord and in the various regions of the body and on the blood-vessels themselves. Through these subordinate centers, under ordinary circumstances, vaso-motor changes take place. The higher vaso-motor center is chiefly called into play by an afferent sensory stimulus. According to that stimulus, it acts in two different ways—either to increase or to diminish in a part the normal arteriole tone.

If we have an increased arteriole tone, the blood-vessels become smaller, and angiospasm is said to exist. Now, the affected part, having less blood, becomes pale, and irritation no longer causes a vaso-motor reflex. If the *skin* is the seat of the spasm, it looks shrunken and anæmic. It feels cold and has the appearance of cutis asnerina. It tingles, and there are present anæsthesia and analgesia.

A temporary or permanent paralysis of the vessels is known as angioparalysis, and it is much more frequent than angiospasm. It depends upon paralysis of the vaso-constrictor nerves, or upon excitement of the vaso-dilators. Now the skin shows bright red or mottled. It is warm, and there is soon an increase of sweat. With the hyperæmia there is an increased sensitiveness to changes of temperature, a subjective sensation of heat, and hyperæsthesia and hyperalgesia occur.

Not only do sensory stimuli reflexly excite the medullary vaso-motor center, but impulses from the cerebrum may also affect it. This is seen in the angioparalysis from emotional disturbance.

With the vaso-motor center in the medulla there is supposed to exist a vaso-dilator center. Its existence has not been definitely proved, but it is strongly surmised. Its action is opposite to that of the vaso-constrictor center, and obviously it gives origin to nerves which cause dilatation of arterioles. The existence of vaso-dilator nerves is assumed from such experiments as dividing the chorda tympani nerve. From this there is no change in the blood-vessels of the submaxillary gland, but if the peripheral end of the nerve be stimulated there is dilatation of the blood-

vessels of the gland, so that the veins discharge bright florid blood, and on section spout blood like an artery.

The same array of phenomena occurs in a similar manner in many parts of the body, especially marked in erectile tissue.

Applying this knowledge to the case reported, let us see what relation each symptom bears to the known phenomena of vaso-motor disturbance.

Seeking for a cause in the case, I find but two available ones—one, the fall on the head when the patient was a child; the other, persistent smoking and chewing.

He states that he received his fall on the head when he was eight years of age, and for many years afterward suffered with feverish head at night. But as he began smoking at nine years of age, the smoking could have been the main factor after all.

Concerning the influence of tobacco or nicotine on the vaso-motor system, I may cite Ostroumoff, who says nicotine is a powerful excitant of the vaso-dilator nerves. When we remember that as a growing lad he smoked a great deal, one cause for his early trouble is apparently revealed. The injury to the head might have modified the functional activity of the ganglionic cells, just as occurs in spinal concussion, or it might have produced a minute hæmorrhage, laceration, or a local softening.

In the patient we have from our examination a permanent dilated condition of the renal blood-vessels, either of one or both kidneys, which dilatation allows the transudation of a large amount of pale urine. There is no inflammation of the kidneys, because no albumin or casts have ever been found in the urine.

This permanent dilatation is of only about four years' standing. It is probable that the use of tobacco is the cause of it all. No doubt he had had repeated attacks of polyuria, which escaped his observation.

At times the urine is slightly lessened in amount; apparently Nature making an effort to constrict the kidney vessels.

The persistent dilatation of these vessels depends upon two things—either stimulation of the vaso-motor dilators to the kidneys or lessened inhibition over their vaso-motor constrictors.

The stimulation of the vaso-dilator nerves might occur from a small tumor, a small blood clot, or some definite lesion involving that portion of the medulla controlling the kidney circulation. Such a lesion would affect the circulation of but one kidney, and that may be so in the case studied. The pain and soreness over the left kidney could be thus explained.

Then any irritation of the vaso-dilators along their course would produce this permanent dilatation. Such irritation might come from adhesions, small tumors, or localized inflammations; but as these nerves run with other nerves and as we have no symptoms of other nerve involvement, we can dismiss it.

A lessened inhibition over the vaso-constrictor nerves to the kidneys could be accounted for by lessened central functional control, or by a diminution in the transmission of this control to the kidneys. Of the latter we have nothing

to indicate, as the spinal cord bearing these nerves is normal.

With the permanent dilatation of the renal vessels, my patient has vaso-motor nerve storms. During cold weather, when his cutaneous capillary system is contracted, a slight stimulus of heat causes a reflex disturbance in the central vaso-motor center, and at once the vaso-dilators cause undue dilatation of all the superficial capillaries, resulting in a condition of angelioparalysis, causing intense and painful hyperæmia of the terminal nerve filaments, which only diminishes on the cause being removed or on relief being obtained by sweating.

I may state that this patient has never noticed any flushing or mottling of the skin during his vaso-motor paroxysms. His wife on several occasions—by no means all—has remarked that he looked pale. He says he thinks the paleness on these occasions was due to anger, as he was always seriously provoked at himself for giving up to the irritation. On one occasion when patient was undergoing my examination he had slight paresthesia, and I had an opportunity of noticing the color of the skin. It was at that time slightly reddened and hotter than normal.

The paresthesia of which he complains has been a distressing symptom, preventing patient from engaging in any work for three months during the past winter. Since the weather has become warm it has entirely disappeared.

Whether the lesion be organic or functional is the first question for us to consider. The persistent polyuria may be and frequently is due to gross lesions, but the fact that the renal discharge has lessened under treatment and that nerve storms, involving both sides of the body, complicate the case, causes me to regard the trouble as functional.

It may have originated and have been kept up by the free use of tobacco, the nicotine acting on the center causing dilatation of the renal vessels and functional instability of all of its cells.

I have tried to ascertain if smokers, as a rule, pass more urine than those who do not smoke, but my observations are as yet of little value.

Is the case one of diabetes insipidus? I think not. While it has in many essential particulars all the symptoms of diabetes insipidus, yet it has more, and symptoms which are exceptional in diabetes insipidus. Both the paresthesia and the furuncles which this patient has had are exceptional in diabetes insipidus, and his thirst has never been the thirst of a patient with true diabetes. The subsequent history of the case shows that it is not diabetes insipidus.

That history is as follows: I gave him in February nuxvomica and arsenic, and later one grain of ergotin three times a day. I saw him last on June 2d. His pulse was 72, his temperature 98° F.

He reported much improvement. For a week he had only had to make water from six to seven times a day. On June 1st he only passed three pints of urine in the twenty-four hours. On June 2d he passed only four pints of urine. Perspires freely. Has no paresthesia. Says he feels well. Has quit smoking, as ordered. The examination of the urine on June 2d showed a specific gravity of 1.022, acid reaction. No albumin, no sugar. No increase of uric acid. Sulphates and phosphates not increased.

CERTIFIED CLINICAL THERMOMETERS.

In the *Report of the Secretary of the Observatory of Yale University* for 1892-'93 it is stated that the assistant in charge of the thermometric bureau is compelled to reject twenty-five, fifty, and even seventy-five per cent. of the clinical thermometers sent for certification, and that those rejected receive double the care and time required by the large majority of those for which certificates are accorded. It is believed that those that are sent for certification by manufacturers are carefully selected, and therefore far more reliable than the average of those sold without certificates.

The *Report* again invites attention to some points in the construction of registering clinical thermometers which are frequently overlooked by makers and users of these instruments. In those forms where the index is a short column of mercury—a third to half an inch long—separated from the rest of the mercury by a small bubble of air, the index is often lost by being thrown down into the bulb, the bubble escaping into the attenuated atmosphere of the tube, and when the index is restored the separating bubble is not likely to be of the same dimensions, and the temperature indications will not be the same as with the former bubble. The difference in the lengths of the tube occupied by the old and new bubbles will account approximately for the differences in the readings. The bubble should always be as small as is consistent with its function of separating the columns of mercury. The tube should extend so far beyond the maximum readings required that the compressed atmosphere at the top of the tube will not force the index back when the support of the mercury in the bulb is withdrawn by cooling.

In those forms where the "indestructible index" is maintained by a "trap" near the bulb, the various constructions of this trap may, at certain points, cause the index to drop irregularly when the mercury below the trap has contracted or may occasion a motion of the index by jumps; in fact, in most of the reliable instruments of this form it is merely a question of the number of jumps taken by the index in rising one degree—most of those in which the index rises perfectly smoothly and without jumps will justify the suspicion that the index will drop as soon as the mercury in the bulb contracts from the trap. While the index is rising freely the motion may appear continuous, but when the index is within a degree or two of coming to rest and rising slowly the jumps may usually be counted easily. The recent practice has been that, when these jumps average 0.1° or less, and the readings repeat themselves throughout, within the prescribed limit of accuracy, the usual

certificate is given; if the jumps average more than 0.1° and less than $\frac{1}{4}^\circ$, the readings repeating themselves as before, the certificate is modified by making the limit of accuracy " 0.2° " on the same certificate form; when the jumps average more than $\frac{1}{4}^\circ$ no certificate is given. The process of producing the trap leaves its walls in a somewhat unstable condition, so that moderate concussions may cause particles of glass to separate, which particles, acting as a plug, may temporarily sustain the index, which, when the plug is dislodged, may drop. The contraction here is so small, and the particles of glass are so fine, that it is not always easy to detect them. The same dropping of the index may be due to the varying effect of air in the trap. For the more certain and rapid counting of the jumps in this class of instruments the assistant has recently contrived an ingenious apparatus which he has now in practical use.

TOTAL REMOVAL OF THE PROSTATE.

ACCORDING to the *Medical Press and Circular* for June 28th, Dr. Dittel, of Vienna, has become an advocate of free operations on the prostate in suitable cases. An important case came before him at the University Hospital, in which the man was suffering from great loss of blood, apparently from the urinary bladder. A diagnosis of stone had been made, but the sound revealed no concretion. Pressure over the vesical region showed the presence of a large elastic swelling at the fundus of the bladder. Rectal examination showed a greatly enlarged prostate. The patient was a laborer, aged thirty-two years. He had had frequent and difficult micturition, from which the catheter had given relief at all times. The endoscope showed a large swelling to the right side of the neck of the bladder, in which there was a small depression whence the blood oozed slowly. The mucous surface had a smooth and nearly normal appearance. The conclusion was reached that vesical calculus did not exist, but that the prostate was the seat of some growth, probably a fibroma.

Dittel's previous experience with operations for the removal of diseased prostates had been unfavorable. He took the course of opening the bladder by the suprapubic operation. This enabled him to see that the loss of blood came from a large prominence at the neck of the bladder. With a scoop he brought away a part of the swollen gland, but the growth was so extensive posteriorly that he was compelled to attack it from below. A curved incision from the coccyx to the anus reached the mass, which lay to the right side of the rectum. The capsule of the prostate was opened and the whole of that organ removed. The recovery was prompt, with only a small escape of urine from the wound for a few days.

This is Dittel's first success out of four removals of the prostate. It was his wish in this case to proceed in some other way than by extirpation, but he was forced to pursue that course by the conditions confronting him after the first step in his attack upon the growth. He believes that this operation for the removal of the whole instead of a part of the gland can be employed only in those cases where the mass is so situated

in reference to the urethra that the latter need not be injured by the surgeon, and that where the tumor implicates the urethra extirpation must be regarded as impracticable. The removal of a part of the prostate should be preferred in these latter cases.

MINOR PARAGRAPHS.

THE ABUSE OF MEDICAL CHARITIES.

THE British Medical Association is making a determined effort to limit the abuse of medical charities in Great Britain. Its committee urges the establishment of a maximum wage-limit above which persons should not be admitted to gratuitous medical relief, and the appointment of an inquiry officer to investigate the circumstances of doubtful applicants for relief at dispensaries. It advocates the exhibition in a conspicuous place, in a hospital or dispensary, of a placard bearing the inscription: "This institution being established to relieve only those persons who are too poor to pay for suitable medical and surgical aid, notice is hereby given that on and after this date patients will be required to give information as to their means and circumstances, with a view to prevent the abuse of this charity by persons who are well able to pay."

AN ACADEMY OF MEDICINE FOR LONDON.

THE *Medical Week* states that on the 20th of July a number of representatives of the various medical societies of London met at the residence of Sir Andrew Clark, in order to discuss the feasibility of devising a scheme for the federation of the metropolitan medical societies, with a view to the establishment of an Academy of Medicine. As the result of the discussion a committee was appointed to consider the matter and to elaborate a scheme to be submitted to the societies for their criticism and approval. It is hoped that means may be found of preserving the autonomy of existing societies while furnishing a bond of union to further their common interests and to obtain before the public a position worthy of their scientific status.

THE INTERNATIONAL MEDICAL CONGRESS.

THE postponement of the congress until next year—predicted some weeks ago, then officially denied, and now authoritatively affirmed in the dispatch included in Dr. Jacobi's letter, published elsewhere in this issue—is an unfortunate circumstance, chiefly because of its coming so late, at a time when many have made their arrangements to visit Rome. As an offset, it is to be hoped that it will contribute to the attendance at the approaching Pan-American Medical Congress.

CHOLERA AT QUARANTINE.

THE affair of the arrival of an Italian steamer at Quarantine with one or more cholera cases on board seems, as we go to press, not calculated to warrant any apprehension that the disease will reach the city or any of the adjacent shores. However, it emphasizes the necessity of keeping a particularly sharp watch on arrivals from Italy.

A NEW CANADIAN JOURNAL.

WE have received the first number, for July, of the *Dominion Medical Monthly*, published in Toronto and edited by Dr. W. H. B. Atkins and Dr. W. B. Nesbitt, with the collaboration of Dr. A. B. Atherton, Dr. J. H. Burns, Dr. J. J. Cassidy, Dr.

J. Ferguson, and Dr. A. A. Macdonald. It presents a handsome appearance and contains excellent reading matter.

THE ANNALS OF OPHTHALMOLOGY AND OTOLGY.

WE congratulate the editor of the *Annals*, Dr. James P. Parker, of St. Louis, on the flourishing condition of that publication, as shown by the necessity of enlarging it. Its editorial staff includes several well-known ophthalmologists and otologists of various American cities, and its pages show their good work.

ITEMS, ETC.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending August 8, 1893:

DISEASES.	Week ending Aug. 1.		Week ending Aug. 8.	
	Cases.	Deaths.	Cases.	Deaths.
Typhus.....	0	1	0	0
Typhoid fever.....	24	8	27	4
Scarlet fever.....	38	4	42	6
Cerebro-spinal meningitis...	9	10	10	7
Measles.....	179	11	161	9
Diphtheria.....	92	27	94	19
Small-pox.....	2	0	5	0

The American Electro-therapeutic Association will hold its third annual meeting in Chicago, on September 12th, 13th, and 14th. The preliminary programme is as follows: *Discussions.*—(1) What are the Possibilities of Electricity in the Treatment of Fibroid Growths. The discussion will be opened by Dr. J. H. Kellogg, of Battle Creek, Mich. The following among others have been asked to take part: Dr. Georges Apostoli, of Paris, Dr. Georges Gautier, of Paris, Dr. La Torre, of Rome, Dr. Augustin H. Goelet, of New York, Dr. A. Laphorn Smith, of Montreal, Dr. Franklin H. Martin, of Chicago, Dr. Margaret A. Cleaves, of New York, Dr. G. Betton Massey, of Philadelphia, Dr. George F. Hulbert, of St. Louis, and Dr. E. L. H. McGinnis, of New York. (2) The Influence of Frequency of Interruptions and Character of Induced Current Waves upon Physiological Effect. The discussion will be opened by Dr. W. J. Morton, of New York. The following among others have been asked to take part: Dr. d'Arsonval, of Paris, Professor Du Bois-Reymond, of Berlin, Mr. Newman Lawrence, of London, Dr. Larat, of Paris, Professor Edwin J. Houston, of Philadelphia, Dr. Apostoli, of Paris, M. G. Weisse, of Paris, Dr. W. J. Herdman, of Ann Arbor, Mich., Mr. J. J. Carty, of New York, Dr. J. H. Kellogg, of Battle Creek, Mich., Dr. A. H. Goelet, of New York, Dr. S. Weir Mitchell, of Philadelphia, Dr. A. D. Rockwell, of New York, Dr. Frederick Peterson, of New York, Dr. W. F. Hutchinson, of Providence, R. I., Dr. Georges Gautier, of Paris, and Dr. Franklin H. Martin, of Chicago. *Papers.*—The Nutritional Effects of Static Electricity, by Dr. W. J. Morton, of New York; Electro-musical Eccentricities, by Mr. Newman Lawrence, of London; The Graphic Study of Electrical Currents in Relation to Therapeutics, by Dr. J. H. Kellogg, of Battle Creek, Mich.; The Action of the Continuous Current within the Living Tissues as distinguished from the Local Polar Action, by Dr. W. J. Herdman, of Ann Arbor, Mich.; The Therapeutic Application and the Theory of Alternating Currents, and the Treatment of Fibroid Tumors with Electricity, by Dr. Georges Gautier, of Paris; Induction Coils, by Mr. A. E. Kenelly, of the Edison Laboratory; Electrolysis in Tumors of the Bladder, by Dr. Robert Newman, of New York; The Present Position of Electricity in the Treatment of Ectopic Gestation, by Dr. A. Brothers, of New York; Electro-therapeutics in Salpingitis, by Dr. W. B. Sprague, of Detroit; Report of a Case of Ascites cured by Galvanism, by Dr. Holford Walker, of Toronto; The Primary Action of the Galvanic Current on the Blood, by Dr. J. Mount Bleyer and Dr. M. M. Weil, of New York; The Conservation of Energy as a Successful Factor in Electro-therapy, by Dr. Horatio R. Bigelow, of Philadelphia; Synovitis treated by Cataphoresis, by Dr. F. H. Wallace, of Boston; The Use of Static

Electricity in the Treatment of Incipient Insanity, by Dr. W. F. Robinson, of Albany; Further Study of Electrical Anesthesia and Frequency of Induction Vibration, by Dr. W. F. Hutchinson, of Providence; The Absorption of Fibroid Tumors by Mild Electric Currents, by Dr. R. J. Nunn, of Savannah; Some Observations on the Fine Wire Coil, or Current or Tension, by Dr. H. E. Hayd, of Buffalo; The Treatment of Subinvolution by Electricity, by Dr. C. G. Cannaday, of Roanoke, Va.; The Successful Treatment by Electrolysis of Four Additional Cases of Oesophageal Stricture, by Dr. D. S. Campbell, of Detroit; The Treatment of Dysmenorrhoea by the Galvanic Current, by Dr. A. Laphorn Smith, of Montreal; Notes upon some Uses of Galvanism in Surgery, by Dr. W. B. D. Beaver, of Reading, Pa. Several other papers have been promised, but the titles have not yet been announced.

The Shelby County, Indiana, Medical Society.—At the next meeting, on Monday evening, the 14th inst., Dr. J. W. Rucker is to read a paper on Sanitation, and Dr. J. W. Green is to read one on Medical Ethics.

The Death of Dr. Samuel E. Mumford, of Princeton, Indiana, is reported as having taken place on Monday, the 31st ult. The deceased served as a medical officer during the War of the Rebellion, and had been president of the Indiana State Medical Society.

Army Intelligence.—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from July 30 to August 5, 1893:*

WOODHULL, ALFRED A., Major and Surgeon, is granted leave of absence for one month and fifteen days, on account of sickness, to take effect on or about August 15, 1893.

CARTER, EDWARD C., Captain and Assistant Surgeon, is granted leave of absence for two months, to take effect about August 10, 1893.

MCCAW, WALTER D., Captain and Assistant Surgeon, is relieved from duty at Camp Pilot Butte, Wyoming, and ordered to the Presidio of San Francisco, California, for duty.

Answers to Correspondents:

No. 411.—If there is no glycosuria, your diagnosis is probably correct. We would suggest the use of alkalis internally and bathing of the affected parts with water as hot as can be borne, followed by the application of a twenty-per-cent. solution of ichthyol.

Letters to the Editor.

POSTPONEMENT OF THE ELEVENTH INTERNATIONAL MEDICAL CONGRESS.

NEW YORK, August 6, 1893.

To the Editor of the New York Medical Journal:

SIR: The undersigned, chairman of the American National Committee of the Eleventh International Medical Congress, has received the following cablegram: "Dr. Jacobi, 110 West Thirty-fourth Street, New York: Genoa, August 4, 1893. Congress postponed to April, 1894. Letter follows. Maragliano." This official information, communicated by the secretary general of the congress, interrupts the preparations made for it. As many of our medical fellow-countrymen have been preparing to visit the congress, which was to be held on September 24th, I trust you will give the news herewith transmitted the greatest possible publicity.

A. JACOBI, M. D.

HAHNEMANN AND "HYDROPHOBIN."

NEW YORK, June 14, 1893.

To the Editor of the New York Medical Journal:

SIR: Dr. J. S. Leonhardt, in his entertaining reflections on Organic Juices in Therapeutics, published in the *Journal* of June 10th, makes the following statement:

"Hahnemann, in the early part of the present century, experimenting along the same isopathic curve, refined the crude therapeutics of the Greek and used 'hydrophobia' in the treatment of rabies."

I am tolerably familiar with the work and writings of the "sage of Coethen," but I never read or heard of his being addicted to such a practice as above imputed.

In the interest of historical accuracy in therapeutics, I ask Dr. Leonhardt to produce his authority for his statement.

GEORGE F. LAIDLAW, M. D.

Proceedings of Societies.

AMERICAN NEUROLOGICAL ASSOCIATION.

Nineteenth Annual Meeting, held at Long Branch, N. J., on Tuesday, Wednesday, and Thursday, July 25, 26, and 27, 1893.

The President, Dr. HENRY M. LYMAN, of Chicago, in the Chair.

The President's Address.—After some reminiscent remarks relating to the study of nervous diseases, the president called attention to their predisposing causes, and said that we must not be content with the simple recognition of disease, but must be able to classify it ætiologically as well. He then spoke particularly of rheumatism affecting the nervous system. The marked forms chiefly affecting sensation were not so commonly recognized and were frequently ascribed to other causes. They were usually observed in elderly people of a nervous temperament and an arthritic diathesis, and differed from many other similar disorders of sensation in being transient, vagrant, and of brief duration. Among these ailments was a universal prickling over the surface of the skin, sometimes limited to certain points where the patient experienced a sudden sharp prick, like a flea bite. This might interfere with or delay sleep. Another disorder of cutaneous sensation often affected the scalp, and was occasioned by irritation of the superficial nerves of that region. The duration of the attack rarely exceeded a single day. Closely associated with these disorders were the various transient perversions of sensation that might be felt in the Eustachian tubes, in the pharynx, and about the fauces. Another of the symptoms of masked rheumatism was a peculiar and disagreeable feeling in the tongue. This sometimes assumed the severity of a genuine neuralgia, and manifested a greater degree of persistence when associated with obesity, diabetes, or gout than when connected with rheumatism alone. The oesophagus and fauces, and sometimes the muscles of the eyeballs, were similarly affected. These patients were also attacked by a paroxysmal cough associated with headache. The most distressing of all these forms of pain was gastralgia. The previous history and the concurrence of other rheumatic symptoms of a more stable character would, of course, add greatly to the certainty of the diagnosis.

Heterogeneous Personality.—Dr. SMITH BAKER, of Utica, N. Y., read a paper with this title. He defined heterogeneous personality as that condition in which the characteristics of ancestry are not blended into a permanent whole, and reported the case of a little girl who presented frequently recurrent attacks of functional perversions and distress which could not be satisfactorily explained except upon the inference that the dissimilar traits noticeable in her grandparents had not been blended in the personality of her mother, and so had proved to

be the ground-field of the grandchild's affection. But the question arose, Was such a view of the case professional or scientific good sense? We could never answer intelligently until the commoner facts of family life had been more minutely studied. Thus, such trite matters as dreams, somnambulism, the solving of problems unconsciously or subconsciously, the uprush of facts and arguments in the act of composition, and the play of genius, should be investigated. Inquiries in states of acute illness, and the study of moods and transformations of character, etc., all should receive more attention by physicians in order that causation in cases of functional derangement might be the more accurately conceived. In doing this, assistance might be found in many instances of so-called reflex disease. Heterogeneous personality should always be looked for in the neuropathic constitution. But more particularly was this of use in considering the problems presented by neurasthenia and the sexual perversions. Not so frequently, perhaps, was the trouble owing to the commonly assumed overwork, etc., as to the unceasing warfare within between the "lower" impulse and the "higher" determination. Students, professional men, and many others whose physical abnormalities or mental peculiarities revealed the sensitive, easily impressed nature were especially apt to be victims of the uncoalesced personality. Its bearing upon questions of marriage and parentage rendered it worthy of general attention.

Dr. LYONS, of New York, referred to the opposite sides of character as seen among the insane. An educated woman might be agreeable and lovable in her normal condition, but vicious when in the abnormal state. He knew of such a patient who would frequently apologize and do her utmost to resist the impulses to do wrong. He thought that such behavior might be due to abnormality in the development of the cerebral hemispheres or to some interference with the circulation.

Dr. PARSONS, of Sing Sing, N. Y., expressed the view that in persons with a tendency to evil thinking and acting such might be overcome by suitable environment. After a time the absence of restraint permitted of a continuance or permanency of the abnormal condition. This would probably account for many of these cases.

Dr. HINSDALE, of Philadelphia, spoke of two authenticated cases of double consciousness. He thought that the medico-legal features of such cases, as well as those of changes in personality, were of special interest and should be reported and carefully analyzed.

Dr. SEGUIN, of New York, believed that atavism was the more rational explanation. Blending of the characteristics of ancestors occurred normally. It was not right to confound double consciousness of an epileptic nature with conflicts of character and personality.

Dr. J. J. PUTNAM, of Boston, said that the treatment rested upon the systematic development of character. Hypnotism had taught us much in regard to this condition, and brought out certain phases of character in a striking manner. He recommended the development of the inhibitory powers.

Dr. F. X. DERCUM, of Philadelphia, thought the case reported by Dr. Baker recalled the fact that there was lowered vitality at certain epochs in women. Relationship between states of health might account for the peculiar mental variations.

Dr. BAKER referred to the various definitions of personality as being not sufficiently inclusive of the facts to be of accurate use. He urged the importance of the study of the subject, especially in its bearing not only upon the causation of actual disease, but in its relation to all our educational ideas and practices as found to-day in our school system. In this way we might find means of obviating detrimental traits, and also of making dominant those more desirable and healthful.

Detention Hospitals for the Insane.—Dr. MATTHEW D. FIELD, of New York, read this paper. After speaking of the wrongs inflicted upon the insane by committing them to county jails and prisons, there to mingle with tramps while awaiting the appointing of physicians to pronounce upon their mental condition, he gave a description of the Reception Pavilion for the Insane at Bellevue Hospital, and the methods of examination and commitment by the city examiners. He declared the pavilion to be in every respect a hospital, with resident physicians and competent trained attendants. Though a plain and inexpensive building, it served its purpose very well. He advocated the establishment of similar hospitals for the reception of those suspected of lunacy in all large cities. He said that an ideal institution for this purpose would be a hospital constructed on the pavilion plan for the reception of the insane, inebriate, and neurotic, with a small amphitheatre and sufficient wards for proper classification and detention for a reasonable time. A competent visiting resident and examining staff of medical officers should be chosen and clinical instruction regularly given. Such a hospital would secure prompt, humane, and scientific treatment. The opportunity for longer observation and securing histories and examinations would result in more complete and accurate certification. There being no need for hasty transfer to other institutions, the feeble, sick, and certain selected patients could be detained for treatment, and clinical instruction would be easily accessible to the entire medical profession.

Dr. KNAPP, of Boston, said there were no detention hospitals in Boston, and they had felt no urgent need for them under existing Massachusetts laws. A few emergency cases requiring immediate restraint were admitted to the general hospitals. Otherwise they could be taken at once to the nearest asylum on emergency certificates. These consisted of two separate certificates. A bond must be given by the superintendent or one of the physicians to the effect that the patient was to be formally committed or released within five days. This system had proved eminently satisfactory and had rarely been abused.

Dr. MILLS, of Philadelphia, stated that the method described by Dr. Field was in vogue at the Philadelphia Hospital. There was a detention ward for isolating cases of insanity. Two physicians were assigned to examine these patients before commitment. This ward had also been used for several years for clinical instruction.

Dr. PRESTON, of Baltimore, remarked that the lunacy laws of Maryland were inadequate. They were endeavoring to establish a detention ward. At present insane patients were kept at police stations, as no general hospital was prepared to receive them. Their method of dealing with such cases was entirely unsatisfactory.

Dr. PARSONS agreed with Dr. Field, and believed that such a ward would serve to diminish the number of improper cases sent to asylums.

Dr. BAKER thought that a detention ward would prove extremely valuable for suspected cases of insanity as found in private practice.

The PRESIDENT said that in Chicago they had such a ward in the City Hospital where these cases were detained until transferred. Their commitment laws were now quite satisfactory.

The Temperature in General Paralysis of the Insane.—

Dr. FREDERICK PETERSON, of New York, read a paper with this title. He first reviewed the literature of the subject, calling attention to the statements of various authorities that there were in general paresis extraordinary daily variations of temperature, that the average bodily temperatures were subnormal or hyperpyretic, and that axillary asymmetry of temperature

was particularly frequent. With the assistance of Dr. Langdon, the temperature in twenty-five cases from the wards of the Hudson River State Hospital for the Insane had been carefully studied. Observations had been made every two hours for a week in each case, and in ten cases the temperature had been taken in the two axillæ simultaneously every two to four hours for a week.

He had reached the following conclusions:

1. As regarded the average bodily temperature, it corresponded with physiological norms. The statements in literature as to hyperpyretic or subnormal averages could not be sustained.

2. The diurnal oscillations of temperature in paretics also corresponded to physiological norms. Observations found in literature as to frequent extraordinary daily variations in such cases seemed to be absolutely erroneous.

3. Asymmetrical axillary differences were so small that they could not be considered as abnormal, and certainly not of any diagnostic significance.

4. When unusual variations of temperature occurred in general paretics, their cause must be sought for in conditions not related to the pathological phenomena of paralytic dementia, but depending upon other thermogenic features unrecognized by the physician or "masked" by the mental state of the patient. Thus in a case of his series an increasing hyperpyrexia had been noted during the second week's observations, but the pneumonia causing it had been "masked" until the fifth or sixth day, and the patient had died on the sixth day. In another case, where the highest single daily oscillation had been 3.4°, and the average daily oscillations for the week 2.2° F., the patient had had bedsores on the sacrum and heels and undoubtedly been somewhat septicæmic. That the temperature might vary in the paralytic seizures of these cases was not gained, no observations having been taken in such conditions.

Dr. GRAY, of New York, said that a large number of different pathological conditions were often included under the name of general paresis. He thought a number represented the terminal stages of intracranial syphilis.

Dr. ISAAC OTT, of Easton, Pa., did not believe that the heat centers could be located from the symptoms of general paresis.

Dr. PUTNAM had occasionally noted oscillations of temperature in paretics.

Dr. B. SACHS, of New York, agreed with Dr. Gray as to the question of diagnosis. The results of his observations coincided with those of Dr. Peterson. He had recorded the rectal temperature. Elevations were often due to complications from gastric disturbances. The temperature was usually a little higher than in those who had no organic disease. He inquired if clinical studies of the heat centers had ever been made.

Dr. OTT said that he knew of only two cases of pistol-shot injury to the brain associated with immediate rise of temperature.

Dr. PARSONS remarked that in one of his cases the temperature had always been normal.

Dr. MILLS regarded the manifestations of general paresis as so diverse in character that we could thus account for the different experience of various observers.

The Anatomical Changes in the Spinal Cord in an Old Case of Infantile Paralysis.—Dr. JOSEPH COLLINS, of New York, presented numerous sections of the spinal cord and reported the history of a case of infantile paralysis of long standing.

Progressive Muscular Atrophy.—Dr. G. M. HAMMOND, of New York, exhibited microscopical specimens and gave the pathological reports of two cases of progressive muscular atrophy, and referred to the fact that considerable confusion was

occasioned by the misapplication of the term "peroneal type" to a disease totally dissimilar to the one under consideration.

The first patient was a woman, aged forty-six years, without history of gout, rheumatism, or syphilis. In the fall of 1889 she stumbled over a chair, bruising the right shin slightly, and a few days afterward she was unable to walk as well as before. Soon after there was marked weakness of the flexors of the foot and the extensors of the toes. By October, 1890, there was complete paralysis of the entire right leg, with reaction of degeneration, loss of power and electrical contractility of the anterior tibial muscles of the left leg, and atrophy and loss of power of the thenar and hypothenar muscles of the right hand. Gradually but rapidly the other extremities became involved, and ultimately the abdominal and intercostal muscles were affected. She died suddenly from either cardiac or respiratory paralysis. The sections of the cord showed sclerosis of the pyramidal tracts, atrophy of cells in the anterior horns, and degeneration of Gowers's column throughout its entire extent. The conclusions to be drawn from the clinico-pathological study of this case would be that the muscles of the hand were supplied by the mesial group and the muscles of the forearm from the anterior group of cells in the anterior horn.

In the second case, seen in 1882, the disease only affected the muscles of the left thumb. The author had had the opportunity to watch the case to its termination, in 1893. It ran the usual course and was in every way typical. At the time of death all of the muscles from the level of the armpits upward, except the facial muscles, were atrophied, as well as those of the upper extremities. The woman became maniacal and finally died from exhaustion. The cord and medulla were examined, and the changes were identical with those described in the preceding case.

He concluded that these cases demonstrated that progressive muscular atrophy was due to a degeneration of the cells in the anterior gray masses and the antero-lateral white columns; also that it was superfluous to divide progressive muscular atrophy into different types because the disease did not invariably begin in the same group of muscles.

The last two papers were discussed together.

Dr. MILLS agreed with Dr. Collins as to the arrangement of cells presiding over the flexors and extensors. He suggested examination of the nerve roots at the extreme limit of the lesions.

Dr. SACHS thought such a careful pathological study would ultimately lead to better results than the usual clinical methods. That the Aran-Duchenne type was of spinal origin there could be no doubt, but he was not certain that Dr. Hammond's case represented the peroneal form of progressive muscular atrophy as described by Charcot, Tooth, Hoffman, and himself. If the case had been such, the findings in the spinal cord would have been of great importance. He was not yet certain whether the peroneal form represented a spinal disease or a peripheral affection.

Dr. PUTNAM had had a case in an adult where there had been rapid destruction of gray matter throughout the cord. Despite the violence of the process, portions of the anterior and lateral cell groups were preserved.

Dr. PRESTON inquired as to alterations in the blood-vessels. He believed this was the primary pathological change. He also asked if Dr. Collins had examined cross sections of the mixed nerves.

Dr. GRAY thought it very difficult to make a positive clinical diagnosis between the central and peripheral portions of the lesion. This was often illustrated in the class of cases reported by Dr. Hammond.

Dr. COLLINS said that his investigations extended over greater ground than his paper suggested. There was diminution in the

size of the vessels, but no evidence of atheroma. The mixed nerves had not been examined. He thought the hæmatoxylin stain useless for a study of the cellular structure.

Dr. HAMMOND concluded that the peroneal type was simply progressive muscular atrophy beginning in the peroneal muscles.

Optic Neuritis, Blindness, Deafness, and the Knee-jerk in Cerebellar Disease.—Dr. DERGUM read a paper with this title. He thought many of the symptoms of cerebellar disease were both inconstant and variable. They were difficult of explanation and frequently impossible to correlate. He desired to call attention more especially to the optic neuritis, the blindness, the deafness, and the modifications of the knee-jerks. He related the history of seven cases in which these symptoms had been present. It was a matter of common experience that very high grades of neuritis might exist without marked impairment of vision. It would seem, therefore, that the added symptom of blindness gave a special significance to the optic neuritis found in these cases. It would appear that for some reason, if there was optic neuritis at all in cerebellar disease, it was apt to be intense in character and, further, was likely to be associated sooner or later with total blindness.

The proximity of the quadrigeminal bodies had naturally suggested itself as in some way explaining this blindness. The ataxia and titubation present in these cases referred us at once to disease of the vermiform process. A consideration of anatomy, as well as the autopsy in one of his cases, would show that if a growth was situated in the vermiform process, especially anteriorly, and continued to enlarge, it would sooner or later press upon the superior cerebellar peduncles and very probably upon the quadrigeminal bodies themselves. When we recalled the relation of the fibers of the optic tract to the primary optic centers, we could readily understand how, if pressure or irritation occurred at this point, a neuritis should be a consequence. Further, the irritation being direct, we could perhaps understand why the neuritis should be of a high grade, and, finally, also why this neuritis should be associated sooner or later with total blindness.

With regard to the deafness which was present in some cases of cerebellar tumor, it might perhaps be explained in a similar manner. The studies of Spitzka, Monakow, and others had made it extremely probable that the posterior quadrigeminal bodies stood in the same relation to the auditory fibers as the anterior did to the optic fibers. It would simply be necessary, therefore, to our explanation that the pressure should involve these structures in order that deafness should be a symptom.

When we turned our attention to the knee jerk we met with a problem of peculiar difficulty. It would seem that one would be justified in accounting for the loss of knee jerk, when observed in disease of the cerebellum, by the loss of muscle tonus.

It was extremely probable that lesions of the cerebellum acted like lesions elsewhere, in one of two ways—*i. e.*, either by destroying tissue and thus destroying function, or by acting as irritants. It was perhaps in this way that we could account for the fact that in some cases of cerebellar disease the knee-jerk was absent and in others present or exaggerated.

Dr. GRAY hoped that Dr. Dergum's explanation of the symptoms would prove true, and asked if the pupillary reflexes had been observed.

Dr. DERGUM replied that when the disease had advanced there was loss of reflex action to light.

Dr. PUTNAM spoke of a case of long-standing optic atrophy and practically no other symptoms. Although the optic neuritis persisted for two years, the autopsy showed a cyst and tumor of the cerebellum.

Dr. PRESTON asked if distinct loss of muscular sense had existed in Dr. Dergum's case. He had noted this symptom in two patients. In four of his cases the knee-jerks had been irregular, disappearing and occasionally returning.

Dr. KNAPP said that in all his cases, confirmed by autopsy, there had been neuritis or optic atrophy. In one case, where cerebellar tumor had been suspected, neuritis had not developed. Blindness had not been so constant. In another case the light reflex was lost when the pupils became dilated. Pressure on the corpora quadrigemina was most likely to produce blindness. He had never noted deafness. As to disease of the middle lobe of the cerebellum being responsible for the ataxic gait, he thought this view untenable.

Dr. LESZYNSKY, of New York, said he had observed a number of cases, two with autopsy. He thought the concomitant basal meningitis had much to do with the production of the optic neuritis, by extension of the inflammatory process along the nerve sheath. In many cases the neuritis was a late symptom. Where the neuritis or optic atrophy was accompanied by loss of light perception the pupillary reflex was always absent.

Dr. DERGUM did not believe the neuritis due to pressure, but more dependent on the location of the tumor. In his cases the neuritis had always been of high degree. Neuritis, blindness, and deafness indicated pressure on the mid-brain. He should look for cerebellar symptoms where the knee-jerk was variable.

A New Method for the Reduction of Dislocation of the Cervical Vertebrae.—Dr. G. L. WALTON, of Boston, in a paper upon this subject, said that since the publication of sixteen cases that had previously come under his notice he had seen several of similar character, and the fact had led him to the belief that this condition was not rare, though frequently overlooked. Reduction by extension usually attempted was unsuccessful. Spontaneous reduction had occurred, showing that direction was more important than force. This fact had led him to the discovery of the method theoretically correct, as shown by manipulation of the vertebrae and by experiments upon the cadaver made by Dr. Richardson, of Boston, and himself. The method had been recently demonstrated in practice by Dr. Beach at the Massachusetts General Hospital with successful result. The author continued, in illustration of the method: "Suppose the left articular process of one vertebra has slipped forward over that of the vertebra below and fallen into the depression anterior to the articular process. This bends the head to the left and turns the face to the right. The reduction is accomplished by extending the head diagonally backward to the right, so as to elevate the articular process, after which rotation to the left replaces the displaced vertebra. The transverse processes on the right act as a fulcrum. The ligaments which hold the vertebra firmly in the false position make no opposition to this manœuvre, which requires no force. In bilateral dislocation the same movements should be made, first on one side, reducing it to unilateral displacement, then on the other."

Dr. PUTNAM said that cases were more numerous than was supposed, and cited the instance of a man injured by a fall, who accidentally died through carelessness in his removal to a hospital.

Dr. SACHS asked if this method would be practicable in other than recent cases.

Dr. WALTON replied that the operation had been performed in one case of about ten days' standing. A case in which bilateral dislocation was produced spontaneously, with perfect recovery, would lead him to recommend the attempt at reduction, even after a number of months, should there be no doubt as to the diagnosis.

Acromegaly, Gigantism, and Facial Hemihypertrophy.

—Dr. C. L. DANA, of New York, read a paper with this title, and reported the history of a case of acromegaly with autopsy, also a case of gigantism or somatomegaly with some symptoms of acromegaly. The giant had a unilateral facial hypertrophy.

The first case was that of a full-blooded Bolivian Indian who was exhibited as a giant. He was thirty years old, height six feet seven inches, weight three hundred pounds. He had an enormous development of the malar and frontal bones. His thorax measured fifty inches in circumference. He died suddenly. On autopsy, the brain was found normal; weight, fifty-five ounces; the pituitary gland was greatly enlarged, measuring an inch in diameter. The thyroid weighed four ounces. The feet and hands had increased circumferential measurements. The brain presented interesting peculiarities of fissuration.

The second case was that of a professional giant, seven feet five inches tall, weight three hundred and fifty pounds, aged nineteen years. His muscular development was feeble. He had several symptoms resembling those of acromegaly. His most curious condition was a progressive unilateral facial hypertrophy, due mainly to osseous growth. It suggested an acromegaly attacking only half of one extremity. Only eleven cases of this affection were on record.

Dr. Dana said that acromegaly was sometimes associated with gigantism. He thought that many so-called giants were instances of pathological growth rather than excessive physiological development. There was much evidence to show that the pituitary gland had some function in these disorders. Among twelve autopsies, this gland had been found enlarged in ten.

Dr. DERGUM said that acromegaly was not associated with increase in the length of bones, but in their width. He regarded Dr. Dana's case as one of gigantism with acromegaly superadded.

Dr. GRAY considered it a question whether acromegaly and gigantism were not identical. We were still in the dark as to the pathology of acromegaly. He thought the cases presented did not warrant Dr. Dana's conclusions.

Dr. COLLINS looked upon them as two separate diseases. In gigantism the changes were in the cellular structure of the diaphyses and epiphyses, principally the former. In acromegaly the changes were confined to the epiphyses. Probably the disease of the pituitary gland stood in proper relation to acromegaly. Much depended on the method of examination. He had destroyed the gland in animals to see if acromegaly developed, but they had all died. He thought giants might suffer from acromegaly, and regarded it as a degenerative disease.

Dr. BRILL, of New York, asked what structures in the brain were usually involved.

Dr. COLLINS answered, the glandular structure of the prehypophysis.

Dr. DERGUM expressed the view that, as the other ductless glands were so often enlarged in acromegaly, to select a single gland seemed precipitate. No doubt the pituitary body might have important functions.

Dr. PUTNAM said that investigators had destroyed the gland in animals, producing polyuria, thirst, and debility. In view of the small number of autopsies we could not dogmatize. The gland had been found normal in three out of nine reported cases. He had seen temporary improvement in one case under the administration of thyroid extract. We were dealing with abnormalities of development and could not expect to discover lesions as the cause. In ten autopsies that had been made the thyroid had been found wasted in seventy-seven per cent.

Dr. SACHS was of the opinion that both conditions were re-

lated. Gigantism was a form of physiological excess, while acromegaly was a distinct morbid condition. He did not attach much importance to the influence of the pituitary body, but thought our knowledge of the exact etiology and pathology was still defective.

Dr. WEBER, of New York, had seen two cases. One patient had had symptoms of myxedema. He was inclined to believe gigantism to be excessive physiological growth.

Dr. MILLS had found at an autopsy a tumor that had destroyed the pituitary gland, but there was no acromegaly.

Dr. DANA said we did not know the functions of the pituitary gland in its relation to acromegaly, but it was certainly of some importance. He still believed in the clinical relationship between gigantism and acromegaly, but looked upon gigantism as an irregular type. He regarded gigantism as a pathological condition. The thyroid had not been enlarged in his case, but the pituitary gland had.

Thyroidectomy in the Treatment of Graves's Disease.

—Dr. PUTNAM read a paper on the treatment of Graves's disease by thyroidectomy. After calling attention to the fact that this operation had been done some forty times, mainly by German surgeons, with but two deaths and a very large percentage of cures or improvements, the speaker narrated a case from his own experience. It was that of a young woman suffering from a typical form of Graves's disease, of nine months' standing, and with a rather large goitre. The right lobe and most of the isthmus were removed. During and after the operation the patient's pulse ran up very high, and for several days she lay in an extremely prostrated and apparently critical condition. She then rallied, and now, at the end of six months, her condition was decidedly better than before the operation, though she was far from being cured. The remaining portion of the tumor had not shrunk and still showed a marked tendency to vascular enlargement. The voice was reduced to a whisper under the immediate influence of the operation, but had now nearly recovered its natural tone. This was not an unusual occurrence.

Dr. Putnam analyzed the reported cases from the following points of view: The immediate and remote effects of the operation (including the mortality rate after operation for goitres in general); the influence of the character of the tumor on the result; the degree and persistence of the improvement in favorable cases, and the character of the operation.

Finally, the question as to the nature of Graves's disease and the relation of the other symptoms to the goitre was discussed. It was pointed out that this relationship was probably based on the fact that the thyroid had important vascular functions. Strong emotions are capable of causing temporarily most of the symptoms of Graves's disease.

The reasonableness of the operation lay in the fact that in Graves's disease certain nervous centers were in a state of extreme irritability. Any means which would cut off a considerable number of excitations from reaching the unstable centers was likely to be beneficial by securing for them a partial physiological rest. There were various means, such as complete rest, the treatment of the naso-pharynx, etc., which might do this in a measure, but no one means was so effectual as thyroidectomy. The operation was, however, attended by a slight risk of death and by a greater risk of considerable temporary prostration and laryngeal paresis.

Dr. DERGUM had recorded the case of a man with all the symptoms of Graves's disease but the enlarged thyroid.

Dr. WEBER had noted recovery in a patient having all of the characteristic symptoms, under the persistent use of iodide of potassium. The dose had gradually been increased to three drachms daily.

Dr. E. D. FISHER, of New York, thought it would hardly seem probable that in Graves's disease the enlarged thyroid could be considered as acting in a mechanical way in producing the symptoms. He had seen many cases in Canada in which apparently no symptoms were produced. These persons had continued in their regular occupation without discomfort.

Dr. PUTNAM said that a large number of instances of goitre without symptoms had been reported, with autopsies. The patients, children in particular, had suffered from debility and there was dilated right heart. He gave a *résumé* of our present knowledge of Graves's disease, both experimental and clinical. He concluded that we had not sufficient data to establish a physiological basis for the disease.

Tabes and Syphilis.—Dr. SACHS, in a paper on this subject, assumed that recent statistics of Erb and others proved the close relationship between syphilis and tabes. This was established furthermore by—

1. The frequent occurrence of general paresis with tabes, and of tabes in the course of general paresis.

2. The occurrence of symptoms in the course of tabes which were often due to syphilis—the ocular palsies, loss of pupillary reflexes, and even the lightning pains.

3. The effect of mercurial and iodide treatment upon many of the symptoms of tabes.

The writer attempted a clinical differentiation of cases of tabes which were due to an active syphilitic process; among these he considered those which exhibited complete loss of reflex contractility of one or both pupils and ocular palsies. He reported *in extenso* a case of typical tabes in which, on post-mortem examination, a more recent syphilitic process had been found superimposed upon an old typical sclerosis. He next referred to the way in which syphilis might cause a spinal sclerosis. He gave reasons for thinking that this was largely due to degeneration brought about by syphilitic disease of the blood-vessels of the spinal cord. Altered states of the blood might be the prime cause of the change in the blood-vessels.

Dr. PRESTON regarded the syphilitic process as an arterio-sclerosis. Rarely was there hyperplasia of neuroglia without changes in the cells or nerve fibers. The tabetic process probably began in the blood-vessels. Traumatism seemed to be a most important etiological factor. He had seen improvement and relief of pain from the use of nitroglycerin.

Dr. MILLS looked upon the active lesions described by Dr. Sachs as probably causative of the sclerosis. Preceding the development of the sclerosis there might be leptomeningitis and disease of the vessels, which, if attacked early, might be relieved or removed; but the sclerosis once established, recovery was impossible. Posterior sclerosis often advanced at intervals by jumps, and these might sometimes be coincident with or follow the revival of active syphilitic processes.

Dr. PARSONS referred to two cases of syphilis followed by insanity and subsequent development of spinal symptoms.

Dr. SEGUIN still adhered to the idea that syphilis was only a predisposing cause for the groundwork of tabes. Certain cases occurred that were undoubtedly free from any history or evidence of syphilis.

Dr. KNAPP mentioned a case of primary syphilis superadded to tabes of two or three years' standing.

Dr. SPITZKA did not doubt that cases of tabes existed without syphilis. He had called the attention of the association to the same pathological condition about eight years ago.

Dr. WALTON thought the frequency of trauma in the production of tabes was overestimated. The ascending degeneration resulting from transverse lesions of the cord or from fracture could hardly be regarded as a typical tabes. If we could get at the real facts in all cases, the cases in which syphi-

lis existed without our being able to elicit the history, they would more than counterbalance those in which we mistook a chancreoid for a sign of syphilitic infection.

Dr. GRAY said there was an anatomical explanation for every symptom in tabes. In all cases he had seen he had been able to distinguish between spinal syphilis and tabes.

Dr. SACHS did not mean to say that spinal syphilis was the same as tabes. We should never omit prescribing the most active antisiphilitic treatment in the early stages of tabes. He did not believe every case was due to syphilis. In the large majority of cases syphilis was the prominent factor.

(To be concluded.)

Book Notices.

The Health Resorts of Europe. A Medical Guide to the Mineral Springs, Climatic, Mountain, and Seaside Health Resorts, Milk, Whey, Grape, Earth, Mud, Sand, and Air Cures of Europe. By THOMAS LINN, M.D., Doctor of Medicine, Faculty of Paris, etc. With an Introduction by THOMAS MUXSON COAN, M.D. New York: D. Appleton & Co., 1898. Pp. xxiii-330. [Price, \$1.50.]

As Dr. Coan has correctly stated in the introduction to this book, the mineral springs of the United States are sufficiently numerous and varied in their special characteristics to meet the demands of any patient; but the American invalid who asks his physician to decide upon a foreign health resort does so because he wishes to have the advantages not only of the resort but also of the sea voyage and the continental travel in which he will indulge as soon as the spring or bath he visits has produced some amelioration in his malady.

The author has prepared this volume for the purpose of giving briefly the necessary information regarding the most important of the European health resorts. He does not purpose that the volume should be encyclopedic, and reference to a number of the minor resorts is intentionally omitted; furthermore, the pages have not been filled with analyses of the various waters. The book is apparently intended to assist the physician in selecting a suitable resort for a patient proposing to go abroad and desiring advice regarding the place that will prove most advantageous for the treatment of his malady; and also to make suggestions to patients who may, for various reasons, prefer going to one country rather than to another, and who desire information regarding the necessary outfit, the expense, and other details connected with a visit to such a place. We believe the book will be found to be a useful medical guide to the European health resorts.

The Treatment of Typhoid Fever, and Reports of Fifty-five Consecutive Cases, with only One Death. By JAMES BARR, M.D., Physician to the Northern Hospital, Liverpool, etc. Introduction by W. T. Gairdner, M.D., LL.D., Professor of Medicine in the University of Glasgow, etc. London: H. K. Lewis, 1892. Pp. x-212.

The author is the first one to have brought to notice the treatment of typhoid fever by continuous immersion in water, the patient being allowed to remain in the specially arranged bath tub for a number of days without removing him for any purpose, unless there is some urgent indication, until the temperature is brought down to the desired degree. The results of the treatment by this method are encouraging. The various complications are considerably reduced in frequency of occur-

rence, and in severity and duration if they occur before the treatment has been begun. This is especially true of pulmonary, cardiac, and intestinal complications.

Nursing in Abdominal Surgery and Diseases of Women. A Series of Lectures delivered to the Pupils of the Training School for Nurses connected with the Woman's Hospital of Philadelphia, comprising their Regular Course of Instruction on such Topics. By ANNA M. FULLERTON, M.D., Physician in Charge of and Obstetrician and Gynecologist to the Woman's Hospital of Philadelphia. Illustrated. Philadelphia: P. Blakiston, Son, & Co., 1891. Pp. xiii-17 to 284.

The author's long hospital experience, both in this country and abroad, has amply prepared her to realize the necessity of giving a surgical nurse a larger scope of information than has been done by her predecessors. Her book is valuable not only for nurses, but also for medical students.

Botany: a Concise Manual for Students of Medicine and Science. By ALEX. JOHNSTONE, F.G.S., Lecturer on Botany, School of Medicine, Edinburgh. With One Hundred and Sixty-four Illustrations and a Series of Floral Diagrams. New York: D. Appleton & Co., 1891. Pp. xiv-260. [Price, \$1.75.] [The Students' Series.]

This text-book is intended and handsomely prepared for the use of students. As the author states, Professor Balfour's teaching is closely followed.

The neat illustrations and floral diagrams, with the appended glossary, facilitate the interpretation of the text very decidedly.

BOOKS, ETC., RECEIVED.

An Ovarian Tumor weighing One Hundred and Eleven Pounds removed from a Child of Fifteen, whose Weight was Sixty-eight Pounds. By W. W. Keen, M.D., Philadelphia. (Read before the Philadelphia Academy of Surgery, May, 1893.)

Laparotomy for Apparent Intestinal Paralysis which caused Arrest of the Intestinal Contents and was Equivalent to Intestinal Obstruction. By W. W. Keen, M.D., Philadelphia. [Reprinted from the *Kansas City Medical Index*.]

The Real Rewards of Medicine. The Valetudinary Address delivered at the Commencement of the Jefferson Medical College, May 2, 1893. By W. W. Keen, M.D., Philadelphia. [Reprinted from the *College and Clinical Record*.]

Proceedings of the State Sanitary Convention, held under the Auspices of the State Board of Health of California, at San Francisco, April 17, 1893.

Miscellany.

The late Professor Credé.—In a presidential address delivered not long ago before the Obstetrical Society of London by Dr. J. Watt Black (*Transactions*, xxxv, 1) we find the following interesting sketch:

"Carl Siegmund Franz Credé was born in Berlin on December 23, 1819. He died from carcinoma of the prostate at Leipzig on March 14, 1892, at the age of seventy-two. His father, who came of a French emigrant family which had settled in Hesse, was a high official in the Ministry of Public Worship and Public Instruction in Berlin.

"Credé began his medical studies in Berlin in 1838, and he took his medical degree there in 1842. He passed six months of his curriculum at Heidelberg, where he made the acquaintance of Naegele. His inaugural dissertation was entitled *De omphaloproptosi*.

"In 1843 he became assistant in the Obstetric Clinic in Berlin, under the direction of Professor D. W. H. Busch, and he held the appointment until 1848. In 1850 he became a Privat-Dozent of midwifery in Berlin. In 1852 he was appointed director of the Berlin School for Midwives and of the Lying-in Department of the Charité Hospital. At his instigation a gynecological clinic was established, and it was put under his charge.

"In 1856 he was called to Leipzig to succeed Jörg as professor of midwifery. He also conducted the Klinik and Poliklinik which Professor Germann had established under Professor Jörg. Soon after he went to Leipzig he founded an obstetrical society in conjunction with Ploss and others.

"In 1875 he was invited to succeed Eduard Martin in Berlin, but he declined on account of his age, then fifty-six years.

"In 1887 failing health led to his resignation of his appointments.

"In 1875, on his refusal of the call to Berlin, the Saxon Government conferred on him the cross of Commander of the Order of Merit, second class.

"In 1847 he married Fräulein Caecilie von Cebrow, and was permitted by Busch to reside outside the Lying-in Institution. He is survived by her and by three sons and five daughters.

"He was renowned as a teacher and beloved by his pupils, and he trained several of the most celebrated obstetricians of our time, including Ahlfeld, Fehling, Leopold, and Sänger. As a teacher, he devoted himself chiefly to obstetrics, but as time went on he also paid much attention to the teaching of gynecology. In the middle period of his professional life he undertook the major gynecological operations, and he was noted for his dexterity as an operator.

"In 1853 he joined with Busch, von Ritgen, and von Siebold in founding and editing the *Monatsschrift für Geburtskunde und Frauenkrankheiten*. When that periodical was discontinued, at the end of 1869, he founded the *Archiv für Gynäkologie*, and he continued to be one of the editors of it until his last illness. In August, 1881, when Spiegelberg died, Credé became sole editor, and he remained so for three years. He rendered signal service to obstetrics and gynecology in founding and conducting those two periodicals. As Leopold says, he was a born editor."

"His *Klinische Vorträge über Geburtshülfe*, or *Clinical Lectures on Midwifery*, is the only large work which he wrote, and it was never reissued after its completion in 1854. It contains the substance of his obstetric teaching.

"A much smaller work, his *Gesunde und kranke Wöchnerinnen*, published in 1866, gives the results of his lifelong experience. Among various interesting sections of it may be specially mentioned those on febrile excitement resulting from mental disturbance, digestive disturbance, retention of milk, etc., and the chapter on the prophylaxis of septicæmia.

"Credé's name will remain imperishably associated with two subjects, both of surpassing importance: the management of the third stage of labor, and the prevention of ophthalmia neonatorum and blindness.

"It was in the first part of his *Klinische Vorträge*, published in 1853, that he first promulgated his method of extruding the secundines. At pp. 599-601 he says that the simplest and most natural means of expediting the expulsion of the placenta is the excitement and the strengthening of the uterine contractions. In innumerable cases he had thus succeeded, without a single failure, in causing the expulsion of the placenta in from a quarter of an hour to half an hour after the birth of the child. He gently rubbed the fundus and body of the uterus through the abdominal wall, and he gradually increased the friction until he induced a strong contraction. When the contraction was at its height he grasped the uterus with his whole hand, so that the fundus lay in the palm, and the body was surrounded by the thumb and the four fingers. He thus, with gentle pressure, expelled the placenta, which he always felt slip out of the uterus from under his fingers. Generally the placenta was extruded entirely from the passages, and, at the least, it came into the lower part of the vagina. At this period he still recommended that when the placenta lay in the vagina it should be extracted by pulling at the funis.

"At the Conference of the Gynecological Section of the Association of German Naturalists and Physicians in Königsberg on September 17, 1860, as reported in the *Monatsschrift für Geburtskunde und Frauenkrankheiten* for that year (Band xvi, p. 337), Credé described his method, which he said he had practiced and taught for several years, as the method to be adopted in natural labors.

"In the *Monatsschrift* for 1861 (Band xvii, p. 274) he published an article, chiefly historical, Ueber die zweckmässigste Methode der Entfernung der Nachgeburt. In that article he said that he now taught and practiced his own method only.

"In an article under the same title in the *Archiv für Gynäkologie* for 1881, Band xvii, p. 260, he states that his method had been misunderstood by many, and that he had expressed the placenta, not only from the uterus, but also from the vagina. Sometimes this was done at the acme of the first or of the second uterine contraction after the birth of the fœtus, but generally at the acme of the third contraction.

"He latterly modified his procedure somewhat, and in the *Lehrbuch der Geburtshilfe für Hebammen*, 5th edition, 1892, p. 104, issued in conjunction with Leopold, it is recommended that the midwife should wait thirty minutes if there is no hæmorrhage, and then express the placenta. This is to be done by grasping the fundus uteri with the hand, the thumb being placed in front of the uterus and the four fingers behind it."

The American Dermatological Association will hold its seventeenth annual meeting in Milwaukee, at the Hotel Pfister, on Tuesday, Wednesday, and Thursday, September 5th, 6th, and 7th, under the presidency of Dr. George Henry Fox, of New York, besides whose address the programme contains the following items:

Antiseptic Treatment of Skin Diseases, by Dr. C. W. Cutler; The Principles of Antisepsis in the Treatment of Eczema, by Dr. H. G. Klotz; Cosmetics, by Dr. R. B. Morison; A Case of Tuberculosis of the Skin simulating Lupus Erythematosus, by Dr. W. A. Hardaway; A Case of Rhinoscleroma, by Dr. G. T. Jackson; Atrophia Maculosa Cutis, with a Case, by Dr. W. T. Corlett; General Discussions on Pityriasis Rosea (its ætiology, its relation to ringworm, seborrhœa, eczema, etc., and its treatment); on Dermatitis Exfoliativa (its clinical forms, its ætiology, and its treatment); and on the question What do we understand by Pemphigus? A Contribution to the Pathology of Acne Varioliformis, by Dr. J. A. Fordyce; Angeiokeratoma, by Dr. J. Zeisler; Lupus Erythematosus as an Imitator, by Dr. H. R. Crocker, of London; and a paper (subject not stated) by Dr. M. B. Hartzell.

The American Public Health Association.—In a preliminary circular dated August 1st, the secretary says that the twenty-first annual meeting will be held under a plan which will differ very materially from that of any former meeting. Through an arrangement entered into by the World's Congress Auxiliary and the association, the forthcoming meeting will constitute an International Congress of Public Health, and committees are already at work to make it a grand success. Invitations have already been extended to foreign countries to participate in the meeting, and to the most prominent sanitarians throughout the world to present papers.

The regulations which will govern this meeting are outlined in this circular. Particular attention is called to the fact that the meeting will be held in sections; therefore persons presenting papers will note under which section their papers will properly come. The classification given under each section will also suggest the topics upon which papers are desired.

It is suggested that members who intend to visit the World's Fair postpone their trip until the meeting of this congress, as there will be no better month in which to see the Fair. Another circular will be issued before the meeting giving additional particulars.

The following is from the circular issued by the committee having in charge the details of the forthcoming meeting:

This congress will be in session in the Art Institute Building, Chicago, October 9 to 14, 1893.

Membership in the congress is open without fee to all persons interested in public health, who comply with the formalities of registration.

The proceedings will be published by the American Public Health Association, and will be distributed to all members of the congress who, on the payment of five dollars and election, may become members of the American Public Health Association. This payment of five dollars entitles the member to a copy of the proceedings, is the only fee required, and is entirely voluntary.

Registration may be conducted in person or by correspondence, and it will facilitate the work of the congress for this to be accomplished as early as possible. To that end an official will be present in the Art Institute to attend registration every day during the preceding week, October 2d to 7th, from nine to five o'clock, and again on Monday, October 9th, during the same hours. Registration may also be accomplished later, according to placards in the hall.

Correspondence on this subject may be addressed to "The Registration Clerk, Public Health Congress, Art Institute, Chicago." Checks should be made payable to the Treasurer of the American Public Health Association.

Registration consists in recording the name, including designating titles; the official representation, if any; the permanent residence; and the local address (this may be omitted or changed at discretion). The particular section the member wishes to work with will also be noted. No charge is made for registration.

Special business meetings of the American Public Health Association will be held each morning, including Monday, October 9th, and also at 4 p. m. Monday, October 9th, for the election of members.

The opening session of the congress will be held in one of the large halls of the Institute, at 8 p. m. Monday, October 9th, and will be devoted to addresses of welcome by the president of the World's Congress Auxiliary, by the mayor of Chicago, and by the president of the American Public Health Association, and to responses by foreign delegates. These will be followed by the Inaugural Address by the president of the American Public Health Association.

The mornings of Tuesday, Wednesday, and Thursday, from ten to twelve o'clock, will be devoted to discussions in general of the meetings of the congresses upon the following topics:

Tuesday.—Diseases chiefly manifested in the air passages: Tuberculosis, diphtheria, pneumonia, their prevention or control through public health service.

Wednesday.—Diseases affecting the alimentary canal: the diarrhœa of childhood, cholera, enteric fever.

Thursday.—The eruptive fevers: Small-pox, measles, scarlet fever, and the diseases of modern life due to nervous conditions.

Friday morning will be given up to a business meeting of the American Public Health Association.

The general meeting of Saturday morning will close the congress.

The afternoons of Tuesday, Wednesday, Thursday, and if necessary Friday, will be devoted to the work of the congress by sections as follows:

I. International, National, and State Hygiene: Its Methods and Relations, including Vital Statistics. ("State," as here used, indicates an autonomous part of a nation, as a kingdom of the German Empire, an integral State of the American Union.)

II. Municipal Health Service. To include the control of the infectious diseases of men and animals, offensive trades, water supply, the disposal of excreta, garbage, and the waste of manufactories, schools, and public assemblages.

III. The Infectious Diseases of Men and Animals: Their Causes, Prevention, and Control.

There will also be general meetings of a popular character at 8 p. m. on Tuesday, Wednesday, and Thursday, when addresses will be delivered on public health subjects of general interest. The object of these is to disseminate general information on such subjects as the prevention of infectious diseases; the causes of ill health due to soil, air, and water; the health and sickness of self-supporters (workers).

All papers that are offered must be received by "The Secretaries of the Public Health Congress, Chicago, Ill.," before September 15, 1893, and titles and abstracts of these by September 1st.

Papers for the congress not written in English should be accompanied by an English translation.

The time for reading a paper in a section is limited to fifteen minutes, excepting when illustration is required or where special extension is granted, when five minutes may be added in each instance.

Thirty minutes is the extreme limit of a paper in the general session. Members desiring to discuss subjects before the congress must send their cards to the presiding officer in order to be recognized. The floor may not be occupied for more than five minutes.

It is desired to make the congress a demonstration of practical methods, and papers on elementary topics or theoretical views can not be accepted. Papers bearing on the objects of the congress are solicited from every source, but their acceptance must depend on the approval of the committees in charge of the congress. These committees are guided in this matter by the standing rules of the American Public Health Association. Resolutions of praise or censure, or committing the congress as such to special views, will be out of order.

The president of the American Public Health Association, which embraces the Dominion of Canada, the Republic of Mexico, and the United States, will be the president of the congress.

Honorary presidents will be appointed from other countries.

Vice-presidents of the congress and of the sections will be made from the countries represented.

All persons from beyond the United States who anticipate being present are requested to notify the secretaries as early as convenient. It will materially assist in the organization for the committees to be informed by October 1st of the Americans who expect to attend.

The Question of the Segregation of Lepers.—*The British Medical Journal* comments as follows on the recent report of the Indian Leprosy Commission: "The commissioners express their belief that neither compulsory nor voluntary segregation would at present effectually stamp out the disease, or even markedly diminish the leper population, under the circumstances of life in India. We invite the attention of the editor of the *Witenhage Times* and other public men in colonies where lepers exist to the comment of the committee on this statement. 'Your committee,' they remark, 'having already expressed their inability to accept the reasoning upon which the commissioners have based the above conclusions, are equally unable to accept the corollary that segregation in any case of leprosy in India is either impracticable or undesirable. They entertain a precisely opposite opinion, and would be sorry if the Government of India were encouraged by the report of the commissioners to refrain from taking the necessary steps in the direction of such segregation of lepers as may be found possible.' The members of the committee who have signed this unequivocal expression of opinion are Mr. Curzon (Under-Secretary for India), Mr. Edward Clifford, Sir Dyce Duckworth, Dr. Heron, Mr. Jonathan Hutchinson, and Mr. Macnamara. Sir Dyce Duckworth and Mr. Hutchinson, however, write separate memoranda, qualifying their adhesion to this document and deprecating the theory of contagion, and disapproving of compulsory segregation. But that still leaves Mr. Curzon, Mr. Clifford, Dr. Heron, and Mr. Macnamara committed to strong dissent from the opinion of the commissioners. The question is, therefore, in so far as the report is concerned, left an open one, and opinions regarding the contagiousness of leprosy and the means of suppressing it must be based upon such facts as are obtainable in this report and elsewhere.

"The wide difference of opinion prevailing on the points in question acquires great prominence from a statement of the medical members of the executive committee. Sir Andrew Clark, Sir W. Guyer Hunter, Sir James Paget, Sir Joseph Fayer, and Mr. Jonathan Hutchinson have expressed their dissent from the opinion expressed in the body of the report of the special committee on the subject of the contagion of leprosy, believing that the evidence of the spread of the disease by contagion is not sufficient to justify the compulsory segregation of lepers, and even seeing no sufficient reason for prohibiting the marriage of the leprosy. It is very clear, therefore, that, so far as the report is concerned, any one who wishes to form a conclusion regarding the contagiousness of leprosy must read it carefully for himself, and draw his own conclusions from the facts stated; and having done so, he must still further extend his studies to the reports and statements regarding leprosy which have been made during the last twenty years

by the Norwegian physicians, who have made it a subject of their life study. It is necessary to emphasize in such a matter the necessity for studying the writings of the Norwegian authorities.

"Without in any way depreciating the value of the commissioners' work in India, to which we have already done justice, it is as well to point out that it is possible to expect too much from the report. The time at the disposal of the commissioners was not sufficient in a question of this kind definitely to determine the chief questions to which they applied themselves. They have done excellent work in compiling valuable statistics regarding the distribution of lepers in India, and have constructed tables of great permanent interest, and they have been able, even in the short time allotted to them, to do much to brush away many of the superstitions connected with the ætiology of the disease; but their opportunities are not to be compared with those enjoyed by men like Hansen in Norway, who has been able to devote continuous work to the subject over a long period of years, with ample material and every assistance from his Government, and with a knowledge of the habits and idiosyncrasies of the population which it is impossible for Europeans to obtain in a country like India. Nothing is to be found in the report which can invalidate Hansen's conclusions regarding contagiousness; and they have been much strengthened by the commissioners, who, while bearing him out regarding the non-hereditary nature of this disease, have been able to suggest no tangible theory which might take the place of contagion in explaining the undoubted existence of leper families. Having in fact admitted that leprosy can be propagated by contagion and inoculation—for we presume that when they state that the extent to which it is so propagated 'is exceedingly small' they must admit that there are cases in which it is so propagated—it becomes incumbent on them to show in what way the cases which they suppose to originate *de novo* differ from those which originate by contagion. This they have not attempted to do. Practically their statements amount to this: A small number of cases of leprosy are caused by contagion; the majority of cases do not arise by contagion, but we do not know how they arise. It is almost impossible to take seriously the *de novo* theory, with its 'sequence or concurrence of causes and conditions related to each other in ways at present imperfectly known.'

"The commissioners have admitted that leprosy is a microbic disease, and they have admitted that in a few cases the microbe is conveyed by contagion, presumably contact with a leprosy individual. What practical difference does it make if we assume, as they do—a perfectly gratuitous assumption, of which they give no proof—that the microbes first get into space, and thence in some unexplained way into a human being? Even according to the statements of the commissioners, if the microbe of leprosy can be destroyed, or its access to human beings prevented, leprosy would cease to exist. We do not wonder, therefore, that men of the world like Mr. Curzon and Mr. Clifford should have agreed with Dr. Heron and Mr. Macnamara in hoping that the Government of India would take such steps to segregate lepers as may be found possible; for, so far as we yet know, the sole habitat and manufactory of the leprosy microbe is the body of the leper, and if we can segregate the leper and disinfect the discharges from his ulcers, we diminish the possibility of the spread of leprosy.

"In making these remarks, we specially have in view the desire to prevent the authorities in our colonies where leprosy prevails being discouraged by the report in their laudable desire to diminish leprosy by segregation. They must examine such evidence as is open to them, and base their action upon that, and not upon the opinions expressed in any reports. We have in a previous article expressed our sense of the merit of the work done by the commissioners, and we would now specially call attention to the great value of that part of the report which so effectually bears out Hansen's demonstration that leprosy is not an hereditary disease.

"Nothing that has happened in recent years can more effectually encourage investigators to search for themselves and form independent opinions than the effective way in which Hansen and the commissioners in India have disposed of this doctrine of heredity—a doctrine which has held a firm footing in medical dogma, and to a large extent influenced human action, for a great number of years. We consider that if the commissioners had done nothing else in India than com-

plete the destruction of this theory, the expenditure of time and the fatigues of the journey would have been amply compensated.

"Above all, we would earnestly urge all those interested not to be satisfied with abstracts of this interesting report, but to study it carefully as a whole. It is only in this way that they will be able to judge for themselves how far Dr. Heron and Mr. Macnamara are justified in stating that they entertain 'a precisely opposite opinion' to that expressed by the commissioners regarding the interpretation of the facts set out in the report."

So-called Craniectomy in Idiocy.—In an editorial, the *Lancet* says: "French Canada enjoys an honorable record in the care and cure of the idiot young. Half a century ago Seguin achieved results quite astonishing in the rescue of these unhappy 'victims to society's misdeeds.' His methods were those of the educator rather than those of the physician, but he broke ground on which medical advance was shown to be possible, inasmuch as he may truly be called the pioneer of that combined system of training, mental and physical, which has been pursued with such gratifying success at Earlswood, in Dublin, and in Dundee. Just sixteen years ago a new and a bolder method was introduced—again from French Canada. Dr. Fuller, of Montreal, advocated craniectomy for the relief of the idiot young, and in 1877 performed the first operation ever attempted with that object. He made an incision in the cranium of an idiot child, with the avowed aim of giving expansion to the cerebrum and of obviating the mischief arising from 'la suture prématurée.' The method was followed up—in France particularly; and on May 9, 1890, Dr. Lannelongue, professor of surgical pathology in the University of Paris, repeated Dr. Fuller's operation on an idiot girl of four years of age, and reported the case to the Académie des Sciences. His success appeared sufficiently encouraging to warrant other operators as well as himself to practice Dr. Fuller's method, and his first report was followed by two memoirs, in which he passed in review the results of twenty-five cases that had come under his own treatment. Of these he claimed twenty-four as 'cures,' and stated that the mean interval between the operation and its successful issue was ten days.

"Dr. Bourneville, one of the clinical staff of the Bicêtre Hospital in Paris, at a recent meeting of the Académie de Médecine read a paper on the entire subject, which, he thought, had been long enough under medical cognizance to justify a review of its present position. What have been the ascertained results of surgical intervention in cases of infantile idiocy? From the intellectual, moral, and physical point of view what benefits can we really trace to it? His answer, though not absolutely discouraging, does not seem to coincide with Dr. Lannelongue's somewhat sanguine conclusions. He admits, amid the scanty information that has come from abroad supplementing Dr. Lannelongue's experience, that 'une certaine amélioration' has in some cases been effected; but further than this he declines to commit himself, and desires more statistics scientifically checked. Nay, he has not been able 'préciser au juste' the improvement witnessed in the favorable cases, which he surmises may be due to the 'soins exceptionnels dont les petits malades ont été entourés.'

"Dr. Bourneville brought to the notice of the academy a collection of crania from the pathological museum of the Bicêtre Hospital, which seem to indicate very pointedly that in the case of idiots and arrested organisms of the same kind there is, generally speaking, no premature junction of the sutures. Moreover, by a series of photographs of the cerebra contained in these crania he demonstrated the existence of deep-seated lesions in the former—lesions of which the gravity awakened doubts as to the curative value claimed for craniectomy in the majority of Dr. Lannelongue's cases. Far too profound, far too extensive as well as intensive, far too diversified in his opinion are those lesions to have proceeded from osseous obstruction, or to be removed or even modified by Dr. Fuller's operation.

"Not only so, but, according to Dr. Bourneville, craniectomy has too often been productive of grave 'accidents,' of actual injuries, such as paralysis and convulsions—sometimes even of death itself. In these circumstances, so far from his counsel being (with Dr. Lannelongue) an abandonment of the medico-pedagogic method initiated by Seguin, he recommends a return to it—a return to it, that is to say, under the

more perfect conditions elaborated by skilled practitioners. Such a system, judiciously applied and perseveringly prolonged in suitable cases, may be expected to result in successes even more signal than those already achieved. At the same time, Dr. Bourneville would hardly induce us to put a veto on surgical intervention in infantile idiocy. Such intervention, practiced in cerebral lesions of apparently an even less hopeful character, has often enough realized expectations to warrant not only its repetition, but its extension to all cases in which osseous obstruction of the cerebrum has been fairly diagnosed. The truth, indeed, seems to lie between the methods of both schools—the surgical and the medico-educational. In Italy, as we pointed out just a year ago, Dr. Fuller's operation has been performed with such success as to have passed into the recognized resources of surgery. We have yet to obtain a series of statistics 'scientifically checked' which shall give us the results of a combination of the two systems—that of surgical intervention followed up, or rather accompanied by, that of the pedagogic authority."

To Contributors and Correspondents.—*The attention of all who purpose favoring us with communications is respectfully called to the following:*

Authors of articles intended for publication under the head of "original contributions" are respectfully informed that, in accepting such articles, we always do so with the understanding that the following conditions are to be observed: (1) when a manuscript is sent to this journal, a similar manuscript or any abstract thereof must not be or have been sent to any other periodical, unless we are specially notified of the fact at the time the article is sent to us; (2) accepted articles are subject to the customary rules of editorial revision, and will be published as promptly as our other engagements will admit of—we can not engage to publish an article in any specified issue; (3) any conditions which an author wishes complied with must be distinctly stated in a communication accompanying the manuscript, and no new conditions can be considered after the manuscript has been put into the type-setters' hands. We are often constrained to decline articles which, although they may be creditable to their authors, are not suitable for publication in this journal, either because they are too long, or are loaded with tabular matter or prolix histories of cases, or deal with subjects of little interest to the medical profession at large. We can not enter into any correspondence concerning our reasons for declining an article.

All letters, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication. No attention will be paid to anonymous communications. Hereafter, correspondents asking for information that we are capable of giving, and that can properly be given in this journal, will be answered by number, a private communication being previously sent to each correspondent informing him under what number the answer to his note is to be looked for. All communications not intended for publication under the author's name are treated as strictly confidential. We can not give advice to laymen as to particular cases or recommend individual practitioners.

Secretaries of medical societies will confer a favor by keeping us informed of the dates of their societies' regular meetings. Brief notifications of matters that are expected to come up at particular meetings will be inserted when they are received in time.

Newspapers and other publications containing matter which the person sending them desires to bring to our notice should be marked. Members of the profession who send us information of matters of interest to our readers will be considered as doing them and us a favor, and, if the space at our command admits of it, we shall take pleasure in inserting the substance of such communications.

All communications intended for the editor should be addressed to him in care of the publishers.

All communications relating to the business of the journal should be addressed to the publishers.

Contributors who wish to order REPRINTS of their articles should do so on a blank prepared for that purpose, which will be sent to them by the publishers on receipt of a request to that effect. The order should be sent to the publishers, and not to the editor.

Original Communications.

AN IMPROVED METHOD OF
DRAINING THE ANTRUM OF HIGHMORE.*By GEORGE W. MAJOR, M. D.,
MONTREAL.

At the regular fortnightly meeting of the Medico-surgical Society, held on November 11, 1892, I explained, in the course of a discussion on antrum disease, a method of operating upon and draining that cavity. A brief *résumé* of my remarks appeared in the *Montreal Medical Journal* for February of this year; but, as I supplied no particulars to the publishers, I take this opportunity of presenting the several points in detail to the fellows of this association. In doing so, however, I do not wish to convey the idea that I am offering an altogether new procedure, although in some respects, perhaps, differing from the methods usually described in the literature of the subject.

Some years ago I tabulated one hundred and eighty-nine cases of myxomatous nasal polypi in which antrum disease presented itself in thirteen instances.

More recently I have a record of eleven examples of antrum disease in which myxomatous polypi of the nose occurred in seven cases, and hypertrophy of the middle turbinated body in the remaining four. In one of these latter—a case which had been previously operated upon through the inferior meatus, in Paris, without any perceptible benefit—double empyema of the antrum was observed; the only instance in which I have observed disease of both sides. That the disease may be intermittent I have no reason to doubt, as I have within the past six months had under my care a patient in whom the discharge only occurred when some acute inflammatory process affected the nasal passage, and in whom, after removing an excess of hypertrophied turbinated tissue and an outgrowth from the septum, the discharge has altogether ceased. So that in all cases I would recommend the removal of nasal obstructions of whatever nature before resorting to the opening of the antrum.

I do not propose to discuss the merits or demerits of making an outlet for the discharges through the nasal passage, but can not refrain from remarking that it seems but reasonable to hold that the counter opening for drainage should be at the lowest possible point attainable, and that, unless very good and sufficient reasons exist to the contrary, this opening should be through the alveolar region. The presence of a diseased tooth is not always an essential concomitant, but the morbid action produced by a diseased tooth, although the tooth has been extracted, may be so perpetuated as to keep up a constant discharge, extending over, as in one instance, a period of twenty-nine years.

A discussion as to whether diseased teeth are the sole

and only cause of antrum disease does not properly come within the scope of this article. I may be permitted to state it as my experience, however, that diseased fangs are the most prolific cause, and that the myxomatous degeneration of tissue found so often in the neighborhood of the ostium maxillare is secondary to the antrum disease. On two occasions I have succeeded in tracing empyema of the antrum as the direct sequence of frostbite of the cheek. Occasionally the swift removal of a diseased tooth and the temporary drainage thus acquired may be all that is necessary to check a discharge. This class of case is somewhat rare, and an opening of a more or less permanent nature is usually called for.

Method of Operating.—When a suitable space is found in the jaw from which a tooth has been previously removed, I apply a ten-per-cent. solution of cocaine, and proceed to drill the bone without further preparation. The instrument I have been in the habit of using for perforating the jaw is simply the ordinary twist drill used by machinists, filed down at the shank so as to fit a dental handpiece. An electric motor is employed for working the drill. The time consumed in perforating does not exceed a few seconds, and the procedure is absolutely painless. I prefer to drill in a slightly oblique direction from before backward; my object in doing so is the better to facilitate the retention of the drainage-tube. The diameter of the drill selected varies somewhat in each particular case. I usually employ two sizes only—viz., five thirty-seconds of an inch and three sixteenths of an inch, the latter preferred.

Immediately after withdrawing the drill, the cavity being cleared of secretions, a piece of soft pine wood, previously whittled down to a size slightly smaller than the drill and with a protuberance at its lower end, is inserted into the opening. A paste of plaster of Paris of proper consistence for taking a cast of the upper jaw is now applied by means of an impression cup and allowed to set. When ready for removal it is gently withdrawn, and with it the wooden plug firmly held in the cast.

The object of using the wooden spile is to get the exact direction of the opening in its relation to the margin of the jaw.

A metal alloy, fusible at a low temperature, is now poured into the cast and a model of the upper jaw with the opening in position is the result. The model is handed to a mechanical dentist, and upon his skill and ingenuity we must largely depend. The drainage-tube I keep on hand in sizes to suit the drills employed, a shade smaller than the latter, however, so as to allow for any swelling and consequent contraction in the caliber of the opening, a suitable length of which is supplied the dentist. The tube is made of pure gold and is drawn to order by a working jeweler.

The tube should at first be of sufficient length, when *in situ*, to stand slightly above the level of the floor of the antrum.

If shrinkage in the length of the opening occurs, as is especially likely when a tooth has been extracted very re-

* Read before the American Laryngological Association at its fifteenth annual congress.

cently, the tube can be subsequently shortened at its antral end. It is well at first to have a tube fully long, as otherwise the drainage may be interfered with by the valve-like action of the recently torn mucous membrane, or by granulation tissue at some period subsequent to the operation.

A sheet of gold beaten out on the metal model will be an exact fit for the gum in the neighborhood of the opening. The gold tube passed through the opening in the model is soldered to the plate and the drainage-tube proper is complete.

When but a single tooth is wanting a pair of arms may be made to loosely encircle the tooth posterior to the space. This will be found sufficient to hold the drainage-tube securely in position, as the oblique direction of the opening in the bone gives to the appliance a counter pressure. When a greater number of teeth are absent the gold base is to be imbedded in a suction plate of vulcanized rubber, to which small clamps may be attached to secure it to the teeth fore and aft. When a plate containing a number of false teeth, or even a complete set, is worn, the tube with its base is readily attached.

For washing out the antrum, I procure an ordinary single-bulb enema syringe (such as Davidson's No. 1, with metal fittings), and file down to a conical point one of the attachments so as to make it perfectly fit the opening in the drainage-tube.

By means of such an arrangement sixteen ounces of liquid may be made to pass into the antrum and escape at the ostium maxillare in less than a minute. To prevent the entrance of food into the antrum, the tube is fitted with a vulcanized rubber plug so designed as to present a rounded head at its lower or buccal end sufficient to prevent its slipping into the tube and to render it easy of removal with the fingers. The tube may be removed at pleasure for the purpose of being cleaned, but should not be allowed to remain out for any length of time, as the opening will be found to contract very rapidly. In my opinion, too small a tube is a mistake, as thickened secretions will not flow so readily as in one of larger caliber. For washing out the antrum I ordinarily employ a solution of boric acid in warm water, and direct the patient to wash out the cavity every three or four hours for the first few days. Peroxide of hydrogen, in varying strengths, I have found to be too irritating for long-continued employment. Where the secretions continue thick and tenacious, an alkaline solution to which a little carbolic acid is added is often useful. For dry dressings I use insufflations of iodol or of iodol and boric acid.

I wish to express my indebtedness to Mr. J. C. Nichol, surgeon dentist of this city, for valuable assistance and practical suggestions offered me in the carrying out of the mechanical treatment of diseases of the antrum during the past sixteen years.

Toronto University.—The *Dominion Medical Monthly* expresses its regret to learn that the financial condition of the medical faculty is unsatisfactory, and states that a special meeting of the senate has been called to consider the matter.

THE USE OF OZONE IN ATROPHIC CATARRH.*

By CLARENCE C. RICE, M. D.

This paper will necessarily be a short one, since what can be said of the chemical composition, physical properties, and therapeutic value of ozone can be easily read in any chemistry or in pamphlets compiled by the Ozone Manufacturing Company of New York. I have used ozone only during the past two months, and while I can not speak decidedly of its value in the treatment of catarrhal diseases, the results so far have been satisfactory enough to warrant calling the attention of this association to its use in atrophic catarrh.

Dr. William J. Morton, of this city, for whom the Ozone Company have manufactured an extensive apparatus for the generation of ozone, and who has used it for various purposes during the past year, first called my attention to the use of ozone in catarrhal disease of the upper air passages, and alleged a therapeutic value for it. Before speaking of the therapeutics of ozone and the method of using it in catarrhal disorders, I may give a short history of what is known of its chemical composition and physical properties and describe the methods used for its manufacture. I am indebted to the Ozone Manufacturing Company of this city for the larger apparatus which they have placed here for your inspection, and to Dr. Augustus Caillé, of this city, who has loaned me the smaller apparatus of Messrs. Labbé and Oudin.

Physical and Chemical Properties of Ozone.—In 1775 Van Marum noticed that the passage of an electrical discharge through the atmosphere produced a peculiar odor, but the reason of this was not discovered until 1840, when Schönbein observed that this same odor accompanied the process of electrolysis in acidulated water. He discovered, too, that these odoriferous gases had the power of decomposing iodide of potassium and liberating iodine. By experimentation it was found that ozone was similar to, though quite different from, chlorine. The credit of discovering the true composition of ozone is due to Marignac and De la Rive, who demonstrated that ozone could be obtained by simply passing a current of electricity through pure oxygen gas. In this way it became apparent that ozone could be nothing else than an allotropic modification of oxygen. Schönbein named this peculiar gas ozone, from the Greek word *ὄζειν*, which means "to emit an odor." The knowledge of the present day in regard to the relation between the two kinds of oxygen— O_2 and O_3 —has been derived principally from the writings of Professor Tait. As is well known, the chemical formula for ozone is O_3 , and it is an allotropic form of oxygen, just as carbon may be found in the allotropic forms of charcoal, graphite, and the diamond. Oxygen may exist in the different forms of O_1 , or active oxygen; O_2 , or common oxygen; and O_3 , or ozone. In the formation of ozone three volumes of oxygen are condensed to form two volumes of ozone—that is,

* Read before the American Laryngological Association at its fifteenth annual congress.

$3O_2 = 2O_3$. In volume, then, it bears the relation to oxygen of 2 to 3. Common oxygen, O_2 , when coming in contact with active oxygen, O_1 , becomes concentrated into ozone, or O_3 . Ozone has been called ozonized air, ozonized oxygen, and electrified oxygen.

From Sir Benjamin Brodie's experiments (*Proceedings of the Royal Society*, 1892, p. 435) it is positive that ozone differs from ordinary oxygen merely in the fact that its molecule contains three atoms instead of two, O-O being oxygen,

Ozone is a colorless gas, quite similar in chemical properties to chlorine. It will liquefy at a temperature of 105° under a pressure of 125 atmospheres, and in this form is of a deep blue.

At one time Schönbein advanced the theory, and it was generally believed, that ordinary oxygen gas was a compound made up of two kinds of oxygen, one being positively and the other negatively electrical. Marignac observed that when oxygen was exposed to the influence of electricity it underwent a contraction in volume and acquired very different properties, its chemical activity being greatly increased.

The ordinary way of obtaining ozone is by means of a Siemens induction tube, which consists of two tubes of nearly the same diameter, one within the other. Their exterior surface is covered with tin foil, and this tin foil is connected with the electrodes from an induction coil. The current of oxygen is passed through the space between the two tubes, and is thus exposed to the electrical current. It is said to be very essential that the oxygen which is to be ozonized should be very pure and very dry. Ozone may also be obtained in small quantities by decomposing water with the electric current. Ozone has remarkable oxidizing power. It destroys substances like rubber, paper, etc. Its effect upon mercury is to deprive it of its mobility so that it will adhere to the surface of a mirror glass. The books tell us that ozone in Nature is principally formed by the action of the sun's rays on oxygen. Schönbein maintains that ozone is the great purifier and oxidizer in the atmosphere, and in a large measure prevents decomposition.

The Ozone Company pamphlet tells us that the utility of ozone as a disinfectant is hinted at by its early discoverer, Schönbein, who in 1851 (*Zeitschrift für nat. Medizin*, Bd. xv, 391) maintained that one part of ozone to 340,000 parts of air was sufficient to destroy the odor of decay in a vessel of 60 litres capacity in which 120 grammes of putrid meat had been placed for a minute, and that Wood and Richardson forced ozonized oxygen through blood in course of decay, and noted that by this means the blood completely lost its offensive smell.

The value of ozone as a bactericide is now under trial by Dr. W. J. Morton and Dr. W. C. Park. I have seen the results of their experiments, but they will be published by these gentlemen later on. Dr. W. Wysschowicz has recently stated, in regard to experiments with bacterial cultures in ozonized nutrient media, that the ozone effected a

change in the nutrition furnished the cultures which prevented their propagation.

The large apparatus for manufacturing ozone, which has been placed at our disposal to-day by the Ozone Manufacturing Company, consists of a dynamo, a blower, a transformer, and an ozone generator proper. The dynamo supplies the current, which then passes for conversion to the necessary high potentiality to the transformer, from which it is conducted by suitable connecting wires to the ozone generator. This latter is constructed of four ozone tubes, placed round and connected by tubes to a central metal pipe, through which the air is received from the blower. The air, passing from thence to the ozonizers, becomes ozonized by the silent electric discharge or effluvium which takes place through the walls of the concentric glass tubes. The blower, driven by a small belt from the dynamo, supplies the air to be ozonized, which, before reaching the generator, is forced through the drying tube. The latter is filled with glass in fine pieces, moistened with sulphuric acid. Ventilators are provided in the sides of the cabinet, containing and supporting the different parts of the apparatus. These are operated by screwing in and out, and they serve to carry off the heat generated by the dynamo when in motion. The longer the air is exposed to the electric effluvium, the greater is the quantity of ozone produced. The flow of the air may be regulated by the valve which will be found at the lower end of the rubber tube, conveying the air to the generator. The blower being provided with a blow-off valve, there is no danger to the apparatus from overpressure. Experience will soon establish the amount of air necessary to obtain the most satisfactory results. When generating ozone, the tubes of the generator should show, in a darkened room, the blue light of the electric discharge or effluvium. The absence of this light shows that either the commutator or drying tube requires attention. Should the ozone be found too irritating, pass the ozonized air through a two-necked Woulfe's bottle containing a solution of caustic potash—a pound of caustic potash to the gallon of water.

The smaller ozone generator which I present to the association was constructed by Dr. Labbé and Dr. Oudin, and has kindly been sent to me by Dr. Augustus Caillé, of this city. Dr. Caillé has used this instrument quite extensively, and published his observations of its use in a paper entitled *Experiments as to the Value of Nascent Ozone in Certain Forms of Diseases of Children, with Demonstration of an Efficient Generator*. Dr. Caillé says of this ozone generator that it is made up as follows: "A mild electric current, from a zinc-carbon cell or storage battery, is sent into a Ruhmkorff or spark coil, and from there enters the inhaler, which is a double cylinder of glass, the inner cylinder being closed and holding an aluminium plate *in vacuo* and surrounded by an aluminium cone. The electrical discharge is not in the form of a spark, but presents a diffuse electrical glow." I suppose that the aluminium tin foil simply acts as a conductor for the electrical current, and thus presents a large electrified surface to the oxygen.

Dr. W. J. Morton began to use ozone in cases of nasal

catarrh without special regard to the kind of nasal disease. The method employed has been to instruct the patient to take a deep inspiration, and then hold the breath while the ozone gas is allowed to pass into the nostrils through the tube. The current of ozone is passed as long as the patient can hold his breath. The patient is then instructed to blow the ozone out of the nostrils before taking the first inspiration of atmospheric air. The degree of irritation produced by ozone upon the nasal and pharyngeal mucous membrane is in proportion to the volume of gas employed, and depends also upon the purity of the gas used. One of the patients accidentally inspired a strong current of ozone, and the next day suffered from an aphonic laryngitis.

Ozone in condensed form irritates the respiratory mucous membrane, and may cause active acute inflammation, etc. In Dr. Caillé's paper, already referred to, he states that Messrs. Labbé and Oudin have published extensive experiments in the use of ozone, and that they allege for its use, first, increased metabolism in consequence of the high oxidizing power of ozone, and, second, the destruction of the tubercle bacillus, in consequence of the oxidizing power and extreme diffusibility of ozone, and its ability to reach directly and indirectly the foci of disease in the lung.

Dr. Caillé's experiments with ozone were employed to test its efficacy in the first stages of pulmonary tuberculosis, in extreme anemia, and in pertussis. His observations extended over five months and comprised twenty-two cases. His conclusions are: That the daily inhalation of ozone increases the oxyhæmoglobin in the blood from two to four per cent. in a short time; that no local improvement was obtained in three typical cases of limited apex tuberculosis, but that, in pertussis, ozone inhalations have a distinct curative effect as regards the duration and severity of the disease. Also that, in anemia, ozone inhalations are exceedingly valuable from a therapeutic standpoint, and give better and prompter results than any other form of medication. And, lastly, that atmospherical disinfection is readily secured by means of the ozone current, making this probably a valuable procedure in the treatment of diphtheria, scarlet fever, and other infectious diseases.

Before calling your attention to my own cases I wish to refer to a paper written by Henry S. Norris, M. D., of this city. The title of this paper is *The Internal Administration of Ozone in the Treatment of Phthisis, with a Report of Cases*.* The report has no special bearing upon the object of this paper, except as it shows that the general tone of the patients treated with ozone was improved. The report covers fifteen cases, fourteen of which are put down as catarrhal phthisis and one as fibroid phthisis. The inhalation of ozone gas was not used in these cases, but aquozone and ozonized cod-liver oil were administered. The aquozone was given, four doses daily of three ounces each, before meals, and half an ounce of the oil containing six volumes per cent. of ozone after each meal. The results in many of the cases were beneficial.

Speaking now of the effect of ozone gas when admitted into the nostrils of patients suffering from nasal disease, I

may say that the first case I observed was treated by Dr. W. J. Morton. He treated this case for the purpose of checking a profuse nasal discharge.

It was a boy of twelve years of age who suffered from apparent nasal obstruction and constant nasal discharge so irritating in character as to keep the upper lip constantly excoriated. He used ozone gas in the nostrils two or three times weekly, covering a period of a few weeks, and the result was that the discharge was almost entirely stopped, the inflamed lip cured, and the patient breathed better through the nose. The patient was sent to me for examination, and I found it to be a case of rather marked adenoid enlargement in the vault of the pharynx. The entire mucous membrane was quiescent at the time I saw him.

I wrote Dr. Morton that in such a case I did not think ozone was as applicable as in atrophic rhinitis, as I believed that the removal of the adenoid would entirely relieve both the nasal obstruction and the pent-up secretions of the nose. It seemed to me that if ozone possessed the powerful oxidizing, germicidal, and bactericidal properties alleged for it, its use would be indicated in those forms of nasal disease which were characterized by decomposing secretions and degenerating tissues, the entire condition possibly depending upon the action of nasal bacteria. Since then Dr. Morton and I have employed the local effect of the ozone gas upon eight different patients, all of them suffering from various grades of atrophic rhinitis and dry pharynx. Of these eight patients, three were treated at the office of Dr. Morton, and he has used a much larger amount of ozone gas than I have at my office. Dr. Morton's apparatus was, as I have said, manufactured by the Ozone Manufacturing Company, while the apparatus at my command is that of Labbé and Oudin. I had the smaller apparatus connected with the storage cells of my cautery battery, and have my patients breathe it into the nose and lungs and exhale it through the mouth. With Dr. Morton's apparatus the current of ozone gas is so strong as to be too irritating for inhalation into the lungs, although it can be modified to any degree. It is hardly necessary to give a detailed history of the cases—that is, the pathological condition in each case—because they are all very much alike.

Three of my cases were advanced to an extreme condition of atrophic change, so familiar to all of you. In two the turbinates had almost entirely disappeared. The septum was ulcerated, and the secretions were collected in thick scabs. Of the two cases I sent to Dr. Morton's office, one was far advanced in atrophic change and the second was but moderate in degree. All of the cases were treated with the ozone gas from five to eight minutes. In Dr. Morton's cases the gas was passed into the nostrils three times—that is, while the patient was holding the breath for three different periods. The immediate effect of the ozone gas was alike in kind in all the cases, but differed in degree according to the volume of the gas employed, and probably according to the sensitiveness of the nostrils. It produced a mild smarting of the nasal mucous membrane for several hours. It increased the secretions of mucus very markedly for eight or ten hours. The congestion of

* Norris. *New York Medical Journal*, November 5, 1892.

the mucous membrane of the nose was also exaggerated. In some of the cases, where the volume of gas was large, the patients complained of headache, which, however, had disappeared by the following day. It was almost the universal testimony of these patients that the nasal pharyngeal mucous membrane was less dry, and that the tenacious secretions were more easily got rid of. For the first twenty-four hours after the ozone was used the patient had the symptoms of a cold in the head, but after that the nose felt unusually clear and the mucous membrane more comfortable than before the application of ozone.

The milder cases of atrophic catarrh were very quickly benefited, and remained improved for several days after the inhaling of the ozone, but most of them relapsed somewhat. The benefit was again obtained, however, by the further treatment with ozone. Whether permanent moistening of the mucous membrane and decrease of secretions can be obtained by the use of ozone can be told only after a longer trial. In the more severe cases the benefit was not obtained so quickly. In all the cases we instructed the patient to discontinue the use of all sprays and douches while we were using the ozone. In a case of *ozæna* treated by this method the deodorizing power of the ozone seemed to be as marked as is obtained by the use of peroxide of hydrogen. The odor from the nostrils was very fetid, but disappeared altogether after the second inhalation of ozone gas. I have used a preparation called by the Ozone Company "therapol," a combination of sweet oil and 8-75 volumes per cent. of ozone, applying it locally on cotton, with an applicator, in two cases of *ozæna*, with the result of deodorizing the nostrils.

As to the manner in which ozone may be expected to produce beneficial results in atrophic disease of the upper air passages, it is known that ozone is an active oxidizing agent, furnishing the active O_3 , which is ever ready to seize upon and form itself into new combinations. Upon this oxidizing power its germicidal properties may be based. It is possible that in atrophic rhinitis there may be bacteria of a peculiar variety, the destruction of which, if it can be accomplished by ozone gas, will tend to greatly ameliorate the disease. Possibly the irritation produced, which we usually term stimulation, is of therapeutic value.

123 EAST NINETEENTH STREET.

The Pan-American Medical Congress.—Papers have been promised as follows for the Section in Pathology: Notes on Three Years' Work in the Pathological Laboratory of the Charity Hospital in New Orleans, by Dr. Henry Dickson Bruns, of New Orleans; The Medical Geography of Puerto Rico, by Dr. A. J. Amadeo, of Puerto Rico; Theories of Inflammation, by Dr. José Torres Matos, of Havana; On Inflammation, by Dr. E. O. Shakespeare, of Philadelphia; On Cholera, by Dr. Herman M. Biggs, of New York; L'État d'hyperexcitabilité du nerf phrénique dans le bérubéri, by Dr. J. B. de Lacerda, of Rio de Janeiro; Paludismo, by Dr. A. J. Amadeo, of Puerto Rico; Bacteriological Observations on the Waters of the Harbor of Havana, by Dr. Acosta and Dr. Grande; Observations on Malaria, by Dr. Coronado and Dr. Madau; The Operations of the Antirabic Laboratory in Havana, by Dr. Acosta; Abscess of the Liver, by Dr. James E. Reeves, of Chattanooga; On Influenza, by Dr. Ramon Gutiérrez, of New York; Observations on the Brains of Feeble-minded Children, by Dr. Henry W. Cattell; The Pathology of Pelvic Inflammatory Trouble, by Dr. Joseph Price, of Philadelphia.

SEXUAL ERETHISM:

ITS NEUROTIC ORIGIN AND TREATMENT.*

By A. D. ROCKWELL, A. M., M. D.

Few morbid conditions cause more unhappiness or are attended with more disastrous results than disturbances of the sexual function. He who sees only here and there and now and then cases of this kind has but little conception of the vast sum of misery around him which is either silently borne or finds expression in some mad act of crime or in suicide. I do not refer so much to those cases of sexual perversion which assume such protean forms and which have been so graphically described by Krafft-Ebing. These people, while in an abnormal mental state as to their genital system, are so in many and perhaps in most instances by choice, through voluntary self-abasement. They cherish this condition of sexual perversion, many of them, as the opium eater and inebriate cherish their destructive appetite. For these perverts we may feel pity, but with it are mingled profound feelings of disgust.

My experience has been that while a certain proportion of these sexual perverts would gladly be free from the chains that bind them, and are eager for help to this end, a far larger proportion are as morally depraved as the followers of any other form of vice, and, equally with them, have capacity for self-reform. There are, on the contrary, a large number of unfortunates who, without fault or wish of their own, are in a continual state of sexual erethism that is abnormal and pathological. Of the many sexual neurasthenics that have fallen under my observation in the course of a considerable experience, I have met with no class that appeals more strongly to one's sympathies. While these cases of priapism with inordinate sexual desires occur among all classes, it is interesting to note here, as in sexual neurasthenia generally, that the largest proportion of cases are found among the educated and intellectual, the moral and religious—men of sensitive natures who are overwhelmed with shame at the idea of revealing their true condition. I have personal knowledge of two cases of this character—in one of which suicide was the final result, and in the other loss of position and reputation. The last case was that of a young clergyman who sought advice for his unfortunate condition only after his prospects had been in a measure wrecked by his failure in an unguarded moment to keep this erotic tendency under control. He could hardly be held accountable for this final libidinous outbreak. The irritation of the erection centers became finally too great for endurance and created a sudden and irresistible impulse.

It should be borne in mind that true priapism is of two kinds—one attended by a peculiar tension or contraction of the intrinsic muscular fibers of the trabecule and sheaths of the organ, of long duration. It is frequently unattended by any marked libido sexualis, but its persistency, continuing as it does for hours and even days, occasions very decided suffering. Its origin may be purely reflex from pe-

* Read before the Section in General Medicine of the New York Academy of Medicine, May 16, 1893.

ripheral sensory irritants, or from causes that are central but organic. More specifically an irritable prostate, hæmorrhoids, stone in the bladder, and phimosis are a few of the pathological conditions that give rise to priapism through pressure on blood-vessels or through reflex nervous influences. The troubles induced through these reflex causes, however, though often severe, are usually transient and amenable to remedies or surgical procedures directed to the exciting cause. More serious are those cases dependent upon tumors or other diseases of the cerebellum and pons Varolii, or lesions of the spinal cord in its cervical or lumbar region.

The other, and perhaps the most important form of sexual erethism to which I especially desire to call your attention, has for its origin neither irritation of the periphery nor lesions of the nerve centers. It is purely functional, and I would apply to it the term "psychical," for the reason that the operations of the mind are involved to a degree not apparent in structural and organic disease of the nerve centers or peripheral irritations. Priapism from central organic and peripheral causes may, indeed, be attended by excessive sexual ardor, as well as by physical discomfort, but the mind is not greatly influenced and the victim is not in any marked degree a sufferer, except as he suffers physically.

Sexual erethism of the psychical type is a very different affair. It belongs to the class of cerebro-spinal neuroses and demands quite other methods of treatment. It becomes, therefore, a vitally important point to correctly diagnosticate between these cases of peripheral origin and those that are central, but at the same time functional. If there is no apparent organic disease of the central nervous system, ordinarily both the surgeon and physician will seek to account for the abnormal sexual condition through some peripheral irritation, and if they find it in hæmorrhoids, in a redundant prepuce, in urethral irritation, or in any one of a number of causes that might be mentioned, and by removing the cause cure the patient, they do a good thing. But if, as I have often observed, these various operations utterly fail to relieve the patient, much time and force have been uselessly expended, and in some instances he has even been left in a worse condition than before.

Some years ago I was consulted by a young man who suffered from abnormal erections and who had actually submitted to two distinct operations—the removal of a redundant prepuce and an operation for hæmorrhoids; and, in addition, an operation upon the eye, as a possible reflex cause, had been advised, to which, however, he did not submit. He was not in the slightest degree benefited by either of the operations, for the reason that no peripheral irritant was responsible for his condition. The cause was neurotic, and he fully and promptly recovered under entirely different methods of treatment.

While acknowledging that many cases of priapism are directly caused by external irritations, and may therefore be relieved by operative procedures, I know too well, from much experience, that in many cases it is vain to hope for relief through surgical measures. The difficulty often is that, in deciding upon the course to be pursued, no dif-

ferentiation of symptoms is attempted. Diligent search is made for the supposed source of irritation, and, when it is found, relief by surgical methods is attempted. The surgeon should not ignore the psychical element, but be sure to eliminate that before resorting to the knife for the cure of a condition that may belong to the class of neuroses. And that it is not so very difficult in many instances to arrive at interesting and important diagnostic conclusions is, I think, illustrated by the following recent case:

Mr. X., a clergyman, aged forty years, came to my office, and, after long delay and marked hesitancy and confusion of manner, related substantially the following history: "I am," he said, "in a most lamentable and even desperate condition. I fear that my memory is deserting me, and that I bid fair to become both a mental and physical wreck." He gave evidence, however, of not the slightest physical weakness, and, as I soon found, when his mind was diverted, both memory and other intellectual processes were as vigorous as ever. He had been married but five years, and, by mutual agreement based on their ideas of personal purity and religion, and perhaps also on an almost complete lack of sexuality on the part of the wife, he had to a considerable degree suppressed sexual inclinations that were naturally very strong. He did not, however, become unbearably annoyed through these efforts of repression until some two years ago, when priapism would occur and continue for hours, diverting his mind from study and irresistibly directing his thoughts in such licentious channels that he became at times overwhelmed with anguish and despair. Intercourse brought only partial and temporary relief, and sometimes he would lie awake for hours after a repetition of this natural effort for relief with erections that would not subside. He was in constant fear that he would commit some act of folly when alone with certain of his female parishioners, and for this reason resorted to methods and excuses to avoid meeting them alone that he thought might seem to them strange and inexplicable. This worried him greatly also, and so he conquered his timidity and reserve and came some hundreds of miles desperate for relief. I ought here to add that, some six months previously, he had been operated upon for a redundant prepuce, but without result. I examined him thoroughly, and although I found hæmorrhoids and a slight varicocele, both of them sensory irritants that might act reflexly on the erection centers, it was evident to my mind that they had little, if anything, to do with the symptoms. The psychical element predominated, indicating that the treatment should be directed to overcoming a neurosis and not a purely physical defect.

The patient was placed upon the use of a suitable combination of the bromides and a bitter tonic, and, what was perhaps as important, his wavering morale was upheld and strengthened by some much-needed instruction and legitimate assurances of recovery. The correctness of this view of the case was demonstrated by the following extracts from a letter which I soon after received from the patient, and I give them because the whole history is most interesting and instructive as a type of a class by no means small: "The results in my case," writes this patient, "have been simply marvelous, and I have a higher appreciation of the skill of a good physician than ever before. When I came to you one great trouble I confessed was 'an imagination utterly corrupt, which prevented any continuous study.' Since using your medicine and following your advice, I find I have a good healthy imagination, almost free from voluptuous images. Again, instead of the unsatisfied, burning desire for sexual intercourse, which came again and again during the day and night, the desire now is very moderate

and at times not perceptible. Instead of repeated erections when alone, all seems comfortable and quiet. Only one of the symptoms I spoke of still remains, and that is the insane desire to take hold of women (who perhaps tempt me), to caress and fondle them and play with them. The presence of certain women excites my passions, but by no means in the same measure as before I began your treatment. Please remember that I never took liberties with women in former years, but was exceedingly proper in all my relations with the sex, and please remember that I have not yielded to this desire, no matter how strongly tempted, yet I find it remains. I can not account for it in a man of my education and habits. I have trembled and do now lest some time it prove too strong for my will. I also told you that my wife was a very chaste woman, and that she regarded my desire to fondle and look at and admire her form as signs of manly weakness. She thinks yielding to these things only hurts me and excites my passions. I can only confess that these desires exist, sometimes almost overwhelming me, and I don't know how to get rid of them. A few words in explanation: That desire to look at and fondle women is much stronger than the longing to have intercourse with them. I have thought at times that if I once went to a bad house and had a good look and nothing else, I would be satisfied and the desire would leave me. Then, again, I have been afraid that this would only be adding fuel to the fire, and that the desire would grow stronger than ever. If this terrible longing is due to some disorder of my system, I want the physician's help; if it comes from a wicked heart, I'll fight it till the day of my death; you, perhaps, can help me to decide."

I might easily relate case after case of this kind as they have from time to time fallen under my observation, but it would simply involve a substantial reiteration of the points of salient interest. What I wish to reiterate and emphasize is, that this excessive sexuality belongs in many cases to the family of the neuroses, is essentially a psychosis, and that it is of the most vital importance not to fall into the error of mistaking a condition due to neurotic inheritance or to environment for one due to simple reflex or direct organic irritation.

And now as to the treatment of these cases:

I know of no greater satisfaction that comes to the physician than to be the instrument of relieving the sufferings of a sexual neurasthenic. The gratitude of one who has recovered from an ordinary acute or chronic disease is one thing, and the gratitude of a sexual neurasthenic who has been freed "from the body of this death" is another, and it is quite certain that by the judicious and persistent use of certain remedial measures much can be accomplished for the relief of these cases. Among medicaments we naturally turn first to the bromides, and, as a rule, we make no mistake in so doing. But that the bromide of potassium should not be prescribed alone to get the best effects that it is capable of giving is a lesson that has been pretty thoroughly learned. In combination with other bromides or with chloral or belladonna, with the zinc preparations, with some of the bitter tonics, or with iron, we have at our command a remedy that is simply invaluable both as an arterial sedative and as an antaphrodisiac. The tolerance of the system to bromides is in some cases very remarkable, and very fortunately so, for frequently it is necessary to persist in their use for many months. As

an illustration of the amount that can be borne, and the length of time it can be taken without apparently injuring the constitution, I may refer to a case of mine in this city in which the patient took for ten years a drachm daily of the bromide of potassium. It is now seven years since her last epileptic attack and five years since she discontinued the use of the bromides, but to-day her general appearance and health and strength are in every way perfect. While this is perhaps an exceptional instance of the great toleration of the system to the bromides, and while there may be temperaments that would be injured by such doses long continued, yet special idiosyncrasies prohibiting its use do not, as a rule, prevail, and by a judicious watchfulness we soon learn when to discontinue the treatment and when to resume it, when to lessen the dose and when to increase it.

Some time ago my attention was called to gelsemium by a patient who professed to have experienced benefit from its use. Recognizing the fact that it acts as a sedative on the excitable nerve centers and reduces the sensitiveness of the terminal nerves, I have been induced to give it a trial, and am quite sure that it has in several cases proved palliative. It is of value more as a temporary expedient and for the purpose of supplementing the action of the bromides when it has been found necessary to discontinue their use for a while. Lupulin is another remedy which may be of some service, especially when given in connection with gelsemium. Monobromide of camphor in doses of three to five grains has in some cases proved useful, but it should be used with care.

A remedial measure that sometimes affords temporary relief is to frequently immerse the organ in water as hot as can be borne. By temporarily distending the superficial vessels relief is afforded to the congested and swollen tissues. Local applications of electricity, however valuable in cases of impaired sexual activity, are, as ordinarily employed, of little value in this condition. Theoretically, however, the galvanic current applied by means of the depolarizing electrode is undoubtedly indicated, and practically it has in several instances, I am sure, served a good purpose. By this method the irritating effect of the cathode is wholly eliminated, and the parts are brought under the influence of the anode alone. The sedative and toning effects of general faradization may also be usefully employed in this condition.

I have confidence in mental therapeutics, especially in the management of the functional neuroses, that has been justified by many special experiments and a considerable experience. Mental therapeutics is an invaluable aid not only in functional nervous conditions, but to a certain extent in organic diseases of the nerve centers and even in acute diseases. In the various manifestations of sexual neurasthenia especially we can often do much toward the relief of the patient by encouraging him to turn his own mental forces on his body. No class of cases tends to more thoroughly depress the patient and take from him all hope and ambition than this, and in no class where the symptoms are so distressing and persistent as in sexual neurasthenia are we so sure of affording relief. These patients,

like so many neurasthenics, are possessed with exaggerated and absolutely erroneous ideas in regard to their symptoms, their origin, possible results, and relation to other symptoms and diseases. They need not only encouragement, but instruction, and it is exceedingly gratifying to note how quickly some of them respond to treatment directed alone to the morale.

A CASE OF SARCOMA OF THE TONSIL.

By JOHN DUNN, M. D.,
RICHMOND, VA.

Mrs. H., aged fifty years, had, in the summer of 1891, "an ulcer of the right tonsil, which her physician burned with the nitrate of silver, causing the ulcer to heal in a short while." From December, 1891, until June of the following year Mrs. H. suffered from time to time with what she termed "little white places on the tonsil," but, as they caused her very little inconvenience, she paid no further attention to them than to gargle her throat with some simple wash. In June, 1892, Mrs. H. took, as she thought, cold, which settled in her right tonsil. *This became rapidly swollen, while at the same time the glands in the right side of her neck began to swell immensely.* At the same time there appeared in the pillars of the right side of the fauces a semi-odematous swelling, involving the whole length of the pillars. After a few days the enlarged tonsil began to bleed, while under a curette the tonsil tissue "broke down as a cancerous womb does." The ulcerated surface was scraped several times, antiseptic washes and solid nitrate of silver being applied to the surface. The glands in the neck became much smaller in size. The swelling of the pillars, however, increased. When I first saw the case—July 25, 1892—the following was the condition of affairs: Considerable induration of the glands in the neck at the angle of the right jaw. These glands were not swollen so that each gland stood out distinct, as is often the case in scrofulous or in syphilitic patients, but they were matted together, as it were, showing a thick infiltrate in the lymphatics among the glands, the swollen mass being apparently rather the result of invasion of the lymphatic system at the angle of the jaw than simply hypertrophied glands. This enlarged area was in no way painful on pressure. The mouth could be opened without discomfort. The right tonsil was seen to be immensely hypertrophied, being enlarged especially at its lower part. Its surface was ragged, irregularly ulcerated, and covered with a dirty, whitish exudate. The secretion from it did not seem to be excessive, *nor was there much disturbance of the salivary system*, since during the examination the patient was not obliged to expectorate once; the odor of the breath was offensive. The pillars on the right side and lower part of the soft palate above were infiltrated, thickened, semi-odematous along their edges, but nowhere ulcerated. The patient's appetite was poor, and she had been losing flesh for the past few weeks. No disturbance in swallowing. The whole of the affected area had a suspicious, "ugly" look. There was, however, one point worthy of note: *The process was not painful.* While the glands of the neck had been acutely swollen the throat had pained, but after they had gone down the pain had disappeared. Of course there was a sensation of discomfort in the throat, but no constant pain. Pieces of the tonsil could be pulled off with the forceps, and would come away so easily as to suggest disintegration of the tonsillar mass. The wounded area would bleed slightly. Neither the hypertrophied tonsillar

mass nor the pillars of the fauces were unusually sensitive to the finger or probe. Treatment consisted in removing from time to time parts of tonsil as it would break down, application of nitrate of silver, antiseptic washes, etc.

August 9th.—No further involvement of the lymphatics of the neck. Pillars of the fauces have become more infiltrated and harder. Most of the tonsillar mass has been removed. Appearance of a tumor of about the size of a pigeon's egg in the soft palate at the junction of the pillars on the right side. This tumor is hard to the touch, but not painful. Nor is the throat as yet the seat of pain; the swollen condition of it, however, makes the patient prefer liquid food. *The absence of pain is so marked that, in spite of the fact that it is little likely a tertiary syphilitic gummatous tumor would produce a similar appearance*, large doses of iodide of potassium are ordered. After taking a few doses symptoms of iodism appeared, while there was superadded a second inflammatory process in the lymphatics of the right side of the neck. This inflammation in a measure subsided under the application of tincture of iodine externally.

19th.—The lymphatics of the whole of right side of the neck, extending beyond the sterno-mastoid muscle, are involved. The tumor in the soft palate has increased in size. The patient complains of a sensation of itching in the right ear, with a constantly present unpleasant sensation in the ear. The post-nasal mirror shows that the chain of lymphatics extending down the right side of the pharynx from the Eustachian tube behind the posterior pillar is immensely enlarged and infiltrated, while the right side of the upper pharynx shows the same swollen, infiltrated appearance. It has not, however, passed the middle line. The itching in the ear is probably due to involvement of the Eustachian tube. The right pillars of the fauces are further hardened and thickened, while the lower part of the posterior pillar forms two or three lobular masses which are beginning to ulcerate. Elsewhere there is no ulceration. The process is further extending below the posterior pillar into the pyriform sinus. *And yet the patient suffers no marked pain. Nor is there any marked salivation.*

26th.—Throat is at last beginning to be painful. Sickening pain, constant, in the right ear. Iodide of potassium quickly produced coryza. Patient has, however, persisted in its use until she is now taking forty minims saturated solution three times a day, and notices little ill effect from the same. Tumor on the soft palate, as well as the infiltration in the right half of the naso-pharynx, increasing in size. Swelling of the lymphatics of the neck has diminished considerably during the past week, until it is the same size it was in July. This swelling is, however, beginning to be painful on pressure. As yet no marked salivation.

September 16th.—Mrs. H. has been to New York to seek advice in regard to operative measures for the removal of the tumor. Several surgeons agreed to undertake the operation, although they all agreed the growth was malignant and gave the most unfavorable prognosis. To have removed the growth, as it was on August 26th, meant the removal of the right half of the soft palate, the right pillars of the fauces in their entirety, the whole of the right retrotonsillar tissues, the whole of the membranes covering the right half of the upper cervical vertebrae from a level with the tonsil to the base of the skull, the pterygoid and hamular processes of the right side of the sphenoid bone, and then the whole of the lymphatic system on the right outer side of the neck. Tracheotomy as a preliminary operation was a matter of course. A possibility of removing the growth entire seemed not to exist. Mrs. H. declined to be operated upon and returned home. Condition to-day: *Absolutely no pain*, that existing in the ear having disappeared. No salivation. No dif-

faculty in speech or swallowing. Appetite good; patient eats whatever she pleases. Sleeps well. Patient has fattened several pounds. Swelling of the glands on the outer side of the neck reduced to two nodules, the infiltration of the lymphatic system of the neck having disappeared. The lower nodule is a little sensitive on pressure. The redness of the pillars and of the tumor in the soft palate has almost subsided, giving place to an anæmic, "solid" œdematous appearance. The anterior pillar is less swollen. The posterior pillar is more swollen than ever and is pushed forward so that its free edge is on a plane with the anterior pillar. The infiltration in the naso-pharynx has increased in size and extends forward at its upper part to the boundary between the nose and upper pharynx, as though it would enter the nasal cavities of the right side. The mass is not painful to the touch, nor is there any ulceration anywhere. Under the suggestion of the patient's family physician, iron and arsenic were prescribed.

October 1, 1892.—The lymphatics of the right neck have within the past two weeks swollen to a degree such as they have never before been swollen, and the swelling has involved the chain to the root of the neck. The swelling has, however, gradually disappeared until to-day there is no trace of it left, except two or three glands lying along the middle and lower parts of the right sterno-mastoid. The pillars of the fauces have diminished in size, are nowhere ulcerated, but are very hard to the touch. The tumor in the soft palate has not diminished, but seems rather to have increased in hardness. The infiltration beneath the tissues of the upper pharynx has apparently diminished in size, as has also the infiltration of the lateral pharyngeal lymphatics. No pain. No salivation. Appetite good. Patient sleeps and feels well. Has gained seven pounds in weight. Within the past day or two there has appeared a desire to sneeze frequently. Nose, however, is clear. Dose of arsenic increased.

November 1st.—Condition of the fauces same as October 1st, except that the growth has increased in size. Uvula pushed over to the left. Growth in the soft palate one fourth as large again as on October 1st. The growth has now filled the space between the faucial pillars from top to bottom on the right side, until it looks like an immense hypertrophy of the faucial tonsil, which it is not, however, as the tonsil, as before mentioned, was entirely ulcerated away. Furthermore, this growth proceeds from the whole length of the posterior pillar. The tumor in the soft palate has a smooth surface, is hard, and has to the finger the sensation of firm cheese. The tumor along the edge of the posterior pillar is lobulated, one of the lobules being as large as the last joint of a man's little finger. The growth is not painful, either subjectively or under pressure. *The glandular swelling of the neck has disappeared*, except in a small area about the level of the hyoid bone, where the glandular tissue can be felt under careful palpation to be slightly swollen. The growth shows nowhere any sign of superficial ulceration, nor any tendency to it. The surface of the growth is pale, anæmic-looking; is nowhere inflamed in appearance. The only inconvenience that the patient has is that particles of food sometimes lodge in between the anterior pillar and the growth. There is beginning to be a muffled tone to the voice. Removed the largest of the nodules for microscopic examination. Under the scissors the growth cuts with as little resistance as cheese would offer; is firm and white, and shows little tendency to bleed.

23d.—Dr. W. M. Gray, of Washington, D. C., reports the part of the tumor sent him to be "a round-cell sarcoma; the small round cells predominate. Although it contains many cells of a larger variety, yet it had best be classed with the small-cell variety." On November 10th I removed under co-

caine, with the aid of a snare and a pair of tonsil scissors, all that I could of the growth below the level of the soft palate, the whole length of tonsillar sinus, and posterior pillar. The roots of the growth were found to extend outward the whole length of the sinus between the anterior and posterior pillars, to spring from the whole length of the posterior pillar. The tumor in the soft palate, which was beginning to ulcerate, was not touched. The throat became very painful after the operation and remained so for ten days, when the surfaces of the cut places began to heal.

December 8th.—The growth in the soft palate has destroyed the mucous membrane over it until its ulcerated surface is as large as a silver half-dollar. Constant annoyance rather than severe pain. Removed the growth in the soft palate beneath the ulceration. Found that it extended through all the tissues from before backward, so that when I was done the posterior pharyngeal wall was visible through the hole. I then found that the growth had sent its prolongations into the tissues about the pterygoid processes. Furthermore, in the postnasal space, filling the lower part of the right side, was a mass of the growth, which seemed to be attached to the chain of lymphatics that runs along the side of the upper pharynx and to the soft palate posteriorly.

January 15, 1893.—The right side of the fauces from the hard palate to the base of the tongue is one ulcerated surface; immense swelling of the glands of the neck on the right side, extending below the collar bone; *swelling of the glands on the left side of the neck*; considerable pain on swallowing. Anti-septic washes are useless. The part of the soft palate between the mass removed December 8th and the free border has ulcerated through, and the lower part of the soft palate, hanging as a flap, was removed. More or less salivation.

February 6th.—General involvement of the pharyngeal region, especially above the soft palate. Patient has great trouble in shutting her mouth. Examination shows that along the anterior border of the ramus of the lower jaw of the right side there has developed a tumor about the size of a partridge egg, perhaps smaller, and when Mrs. H. attempts to shut her mouth the upper jaw shuts down on and squeezes this tumor. Removed with aid of tonsil scissors and cold snare. Bleeding not worth mentioning. This growth resembled the rest of the tumor; cuts like cheese, so that it could be scraped out after the capsule over it had been slit.

25th.—Immense swelling of the glands in the *left side* of the neck followed the last operation. This swelling, however, in a great measure subsided after a few days. There is still, however, considerable enlargement of the left lymphatics.

April 21st.—Increase in size of growth and involvement of lymphatics of both sides of the neck. Growth involves now both sides of the soft palate; has extended into the uvula whole length. No marked salivation. Pain considerable, but chiefly from the neighborhood of the ramus of right side of lower jaw bone, where, owing to involvement of coverings of ramus, there is pain with each movement of the jaw. Removal of the uvula, which was enlarged several times and hung so low in the pharynx as to offer obstruction in swallowing; also as much of the tumor mass about the ramus as thought advisable. There is another point worthy of mention. The growth when cut bleeds scarcely at all, and *wherever it has attacked the muscular tissues it retains its whitish appearance and cheese-like consistence and offers almost no resistance to the knife or wire.*

May 30th.—Removed from the right side of the base of the tongue a piece of the growth of the size of a sparrow's egg. The growth seems to have extended by direct continuity from the lower part of the pillars of the fauces. Patient's nose

breathing is again perfectly free and patient no longer snores. Patient says on May 25th something back of her nose "broke and discharged a good deal of matter." Probably a part of the growth which involved the upper surface of the soft palate. Growth continues to advance along the hard palate and upper jaw. Has gotten beneath the aponeurosis of the right side of the pharynx, which side is elevated half an inch more than the corresponding side. Growth has made its appearance on the right cheek near the angle of the jaw. The area of infiltration is about an inch in diameter. Glands in the neck much smaller than a month ago. Have now to be felt for in left side. No salivation.

The growth in the uvula was examined by Dr. Ward A. Holden, of New York. It was found to be a small-cell sarcoma.

The further history of this case is unnecessary for the purposes of this article.

In regard to the possibility of making a diagnosis of the nature of the growth in July, 1892, a few words may be said. In the first place, the patient's mother had died of "carcinoma of the liver"; then there was early involvement of the lymphatic glands; from the appearance of the tonsil itself, the growth might have been either carcinoma, sarcoma, or tertiary syphilis. In my endeavors to make this growth fit into any description of tumors of the pharynx, I have made use chiefly of Bosworth's excellent work on the throat, and it was my failure to find there, or anywhere else, such an accurate description of the possibilities of a small-cell sarcoma, that decided me to watch this case and report it as it appeared to me. Bosworth's work, then, is used as a text for the following remarks, and the failure of the symptoms and history of this case to correspond in some points with what are the generally received views of the race run by one of the growths of the pharynx is not reported to cast a slur upon what is the best work on the nose and throat with which I am acquainted, but to show that there are still many points in connection with growths in the pharynx which have not received attention.

Bosworth says the development of sarcomatous growths of the pharynx is somewhat insidious (page 373), and the history of the case here reported bears out this statement. To my mind, there is no doubt that the growth had existed at least a year before it came under my observation. The throat trouble, which had existed to a greater or less degree since July, 1891, points to this. In this case the fact that Mrs. H. had had all her life enlarged tonsils, which were always more or less troublesome, would tend to explain why the formation of a painless growth in them did not give her any especial concern. And, furthermore, the hypertrophy of the tonsil explains in a measure, perhaps, why the sarcoma should have had its origin here. Mrs. H.'s mother died of carcinoma, and there is, from what we know of malignant growths, at least a presumption that there is such a thing as an inherited lack of resistance to the formation of new growths in the offspring of parents who have had malignant growths, if there be not an actual tendency to the formation of these growths. In any of the surface lymph tissues wherever hypertrophy has taken place, these tissues are thereafter never free from inflammatory processes until Nature has destroyed by inflamma-

tion the hypertrophy. This is notably true in the case of the faucial and pharyngeal tonsils and of the adenoid basis of the conjunctiva. And there are apparently some reasons for believing that sarcomata will locate themselves at places which are for long periods of time subject to unrelieved inflammation, the sarcomatous principle or tendency being, of course, present. Let us take, for example, the appearance of a sarcoma in the walls of an antrum which for years has been the seat of an untreated purulent process, due to polypus, etc. Bosworth says (pages 381-382): "Sarcoma is usually regarded as a disease belonging to the earlier periods of life; and yet, curiously enough, when invading the tonsil it seems to belong more particularly to adult life. This, I think, is especially remarkable when we consider that the lymphatic tissue which makes up the faucial tonsils is in adult life in a state of almost absolute quiescence or atrophy." I should not be surprised, were statistics at hand to determine the point, if we were to find that sarcomata almost never originate in healthy tonsillar tissue, but in hypertrophied tonsillar tissue, which, as I said above, is never in a state of "absolute quiescence," but always is in an inflammatory condition.

Bosworth (page 383): "The progress of sarcoma differs from that of carcinoma in that this form of malignant disease extends forward to the base of the tongue and palatine arches, whereas sarcoma shows a tendency to remain stationary or to extend backward into the oropharynx. The only instance, as far as I know, in which it has been known to extend forward into the mouth was that of Gray, in which the gums and palate were involved."

This statement is of little value, or is only of value in one of the kinds of sarcoma of the tonsil. Judging from the case of Mrs. H., I should say that a small-cell sarcoma could travel in any direction. In this case it traveled through the pillars, into the soft palate, into the uvula; on to the base of the tongue; into and beneath the aponeuroses of the pharynx; into the tissues of the cheek; into the ramus of the lower jaw; into the gums of the upper and lower jaw. What determines its path of extension I do not know. Certainly not the denseness or looseness of the tissue before it, for it invades and destroys bone as well as muscle tissue. In regard to the involvement of the lymphatics, it surprised me not a little to find my patient at one visit with the whole lymphatic system of one side of the neck swollen and tense, while at the next I could find no evidence of lymphatic engorgement save in one or two small glands which required some search to show their presence. This ebb and flow of the tide in the lymphatics continued with considerable irregularity for about six months, when the glands remained permanently enlarged to a greater or less extent. And, finally, when the sarcomatous process had crossed the middle line of the soft palate and the other tonsil had become involved, the glands of both sides of the neck became enlarged. When I first saw the case the involvement of the lymphatics made me incline to carcinoma as the cause of the trouble. When, after a while, the lymphatic swellings disappeared, the possibility of carcinoma became less. It finally occurred to me that these swellings of the lymphat-

ies of the neck were not due to direct extension of the sarcomatous process to them, but to the presence in the lymphatics of some morbid material carried to them from an inflammatory process set up in or about the growth by its extension. This conclusion was reached by noting that contemporaneously with the acute swelling of the lymphatics of the neck the patient would complain that her throat was sore. Whether in the finally chronically swollen lymphatic glands existed sarcomatous cells could only be determined by the microscope.

Bosworth (page 384) says: "As a matter of fact, the tendency on the part of a sarcoma to become the seat of suppurative or ulcerative action seems to be a comparatively rare event, except such erosions as naturally occur on the surface of the tumor when impinging on neighboring parts." Again, these remarks are not borne out in full by the above case. Hypertrophied tonsils, development in them of a small-cell sarcoma, which rapidly broke down the tonsillar tissue, causing extensive ulceration of the tonsil with destruction, passed into the soft palate and formed a growth which quickly ulcerated over a space the size of a silver quarter; caused the formation of an abscess which had its seat in the upper inner part of the soft palate and which for a while obstructed the nasal breathing. Such is the history here. The ulceration in the soft palate here was due to "superficial caries, the result of rapid cell growth" (Bosworth, p. 385). I can not explain the cause of the abscess.

This case was treated for some months under the supposition that it was ulcerative tonsillitis (cf. Bosworth, p. 385, l. 12).

Hæmorrhage as a Symptom.—It can almost be said that this growth refused to bleed, so little blood would flow as the result of removal by the scissors or snare of large pieces of it. The removed parts were whitish in appearance, showing the fewness of the red blood-cells. Nor was there any marked tendency to bleed from the ulcerated surfaces. The different capacity for bleeding of different sarcomatous growths is a matter worthy of comment. One which I removed four times bled more and more copiously after each removal, until at the time of its final recurrence it had become so vascular that it was with difficulty that so small a puncture as that made by a hypodermic needle could be made to cease bleeding. This, however, was a giant-cell sarcoma.

"The presence of the growth naturally excites an increased secretion from the normal mucous membrane of the fauces" (Bosworth, p. 385).

The absence of any marked salivation, such as is found in cases of carcinoma or epithelioma, is also to be commented on. Naturally at the times when there was an acute inflammatory process at work in the throat, as evidenced by an acute enlargement of the glands of the neck, there was a tendency to marked increase of saliva. But, generally speaking, the increase in the amount of saliva was not sufficient to be the cause of serious inconvenience to the patient.

The absence of marked pain during the early history of the growth is also to be noted. And except the pain,

which was general, at the times that the throat was acutely inflamed (*vide supra*), the pain was rather inconvenience due to the position and extension of the growth than of an acute, localized nature. At one time—about the latter part of August, 1892—the throat was for some reason quite painful for a few days. This was, perhaps, due to the involvement and rapid extension of the process in a new area.

In the beginning of these remarks reference was made as to the possibility of deciding, from the gross appearances of the case, between carcinoma and sarcoma when I first saw the growth. I do not know that it could have been done.

As to treatment—cleansing washes, removal from time to time of parts of the growth as they extended to regions where they were the cause of marked inconvenience, and attention to the general health. The involvement of the lymphatics—not to mention the amount of the faucial tissues involved—made me unwilling to attempt complete extirpation of the growth.

EARLY VIABILITY OF TWIN FŒTUSES.

By H. C. ALLEN, M. D.,

ST. JOSEPH, MO.

THE experience of obstetricians and the records of both single and multiple births demonstrate that the viability of the fœtus is very grave as to prognosis and uncertain prior and up to the termination of the seventh month.

The traditional theory that an infant born at the seventh month is more likely to survive than one born at the eighth has never been borne out by facts, is not correct in principle, and is beyond the pale of reason and ordinary sense. The law in all Nature was and now is that the nearer the bud, germ, or embryo approaches to the mature fruit in either natural or physical development, the greater the probability it possesses of surviving; it is thus the "survival of the fittest."

Playfair writes: "There is little or no hope of a fœtus living before the twenty-eighth week or seventh lunar month." He also writes: "Several cases are on record in which after delivery at the sixth month the child survived and was reared" (page 235).

A. Charpentier writes in the *Cyclopædia of Obstetrics and Gynecology*: "The end of the seventh month is of interest as being perhaps the earliest period at which the fœtus can be born with any reasonable chance of surviving" (page 197).

A case in practice may be of interest, which will add two to the record of viable births at six months and a half.

Female twins were born to Mrs. E. (primipara) at St. Joseph, Mo., February 22, 1893, in premature labor, the development and external appearances assigning them at six months and a half utero-gestation, and this was corroborated by calendar data. Both infants were fairly developed; the skin was thin, dark red, and wrinkled; short white hair appeared on the head and slight down on other portions of the body; the lower jaws and chin were retracted and set farther back; the nails

were semi-formed, covering only half the area of the distal matrices; the upper two centers of the sterna were ossified; the lower three centers were cartilaginous; the upper and lower limbs were of equal length; the eyelashes and eyebrows had just commenced to appear.

Their combined weight two days after birth was three pounds avoirdupois—one weighed a pound and a quarter; the other, a pound and three quarters. Length of fetuses, seven inches and a half and nine inches respectively.

The infants at birth were so small and their advent was so premature that particular care had to be taken to continue to them the small prospect of surviving which they possessed.

They were placed in a large willow basket which was lined with woolen blankets and cotton batting, the basket inclosing three jugs containing hot water and occasionally supplemented by the addition of bottles containing hot water.

These caloric receptacles and radiators were replenished morning and evening to maintain uniform heat, and under the ministrations of a skilled nurse, zealous and attentive, the directions and suggestions of the attending physician were carefully followed with the happiest results.

The infants' mouths were too small to admit the nipples of the breast, being a fourth of an inch in diameter of aperture when distended, and small bottles were provided with pointed rubber nipples, which could furnish an easier method of nursing.

These were filled with milk which had been warmed after being pumped from the breasts of the mother. After five days' feeding in this manner the use of the mother's milk had to be discontinued, on account of a failure in the supply, and an artificial product resorted to.

Peptogenic milk powder was prepared and administered with very favorable results. The infants assimilated it with ease and took it with avidity, and, although they have not grown fat and plump, yet the muscular system is firm and hard, and they increase in strength and evince activity of temperament.

Their combined weight at three months and a half of age is ten pounds and a half—five pounds and five pounds and a half.

From May 22 to May 27, 1893, they were on exhibition in Curio Hall, Eden Musée, St. Joseph, Mo., with their parents in attendance, both in good health and bidding fair to live long lives.

The interesting features which the case presents are:

1. The early period of utero-gestation with viability.
2. The absolute necessity of maintaining the temperature of 100° F., to facilitate the circulation of the blood and aid growth.
3. The importance of carefully measuring and administering a suitable quantity of milk at an elevated temperature.
4. A sedulous regard to rest in sleep, which should not be disturbed by unnecessary waking.

June 1, 1893.

The Death of Dr. Edward F. Mordough, of Brooklyn, took place on Wednesday, the 9th inst. He was a graduate of the Long Island College Hospital, of the class of 1879, and became an *internus* of that institution and one of the first regularly appointed ambulance surgeons of the city. He was well known in official and life insurance circles, but had not been active in practice during the past five years. He had been failing for nearly two years, from tubercular phthisis, on account of which he had lately been obliged to resort to one of the county hospitals for treatment.

THE NEW YORK MEDICAL JOURNAL, *A Weekly Review of Medicine.*

Published by
D. APPLETON & CO.

Edited by
FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, AUGUST 19, 1893.

THE PAN-AMERICAN MEDICAL CONGRESS.

THE announcements that we have published from time to time as to the organization of the congress and of its sections, together with the programmes of the sections, make it reasonably certain that the scientific success of the meeting is now assured. In consequence of the prevailing financial stringency, the attendance from the United States may perhaps not be as large as it would otherwise have been. This makes it all the more important that those gentlemen who have accepted official connection with the congress should make it a point to attend. If they all come, or even a large proportion of them, we shall have, numerically, a very successful congress. All the countries concerned, practically, have appointed official delegates in response to the invitation of the President of the United States, who will open the congress in person. A large number of the colonies and a great many municipalities also have appointed delegates, as well as the medical organizations throughout Latin America.

The Governors of nearly all the States of the Union have appointed delegates to represent the sanitary interests of their respective States. These delegates number nearly three hundred in the aggregate. It will be seen from this that special interest is centering in the Sections in Marine Hygiene and Quarantine and in Hygiene, Climatology, and Demography, in charge respectively of Surgeon-General Wyman of the Marine-Hospital Service, and Medical Director Gihon of the navy. The occurrence of cholera in the East and the perennial prevalence of yellow fever in the South give particular importance to the proceedings of these sections at this particular time.

THE MALIGNANT TENDENCY OF CHRONIC MAMMARY TUMORS.

DR. W. HENRY BENNETT, of St. George's Hospital, has written in the *Lancet* for April 29th concerning the tendency of apparently innocent tumors of the breast to take on a malignant character. He recites his experience in three cases and emphasizes the teaching of many generations of surgeons that the path of safety lies alone in an early removal. There are probably few families in the land that have not had an experience of the dangers of delay in the acceptance of the surgeon's recommendation to free a patient from the perils of a chronic and so-called benign growth of the mammary gland.

One of Dr. Bennett's patients had a lump in the breast that was quiescent seven years. She discovered the hardness by accident, and, as is the custom with very many patients, kept

the knowledge of it to herself for a long while. There was no increase of size, and there was no discomfort, but she was advised by her physician, to whom she ultimately went for advice, that the proper treatment was removal at once, or at least as soon as any inclination toward increase was observed. After about three years the woman was confined. The swelling then became sensitive, but no marked increase took place until three years later. All this time she continued reluctant to have any surgical interference. Finally Dr. Bennett was consulted, and the urgency of the situation was found to require immediate operation.

Upon removal, the tumor was found to be within a well-defined capsule, and only attached to the gland at a single point. The external parts of the tumor were clearly an adenofibroma, but in its center lay a rounded mass of semi-gelatinous material, to which the tendency of the once innocent lump to grow was due. This softish central mass was found to be of the nature of a spindle-celled sarcoma, and it was at all points surrounded by a layer of tissue identical in structure with the chronic and quiescent adenofibroma. At one point, however, the sarcoma approached very close to the surface, so that the benign overlying tissue could hardly be discerned. The entire mamma was removed.

The author is decidedly of the opinion that the growth was originally wholly an adenofibroma, and that the sarcomatous element had only recently been superadded. The chronic tumor was a weak point in the breast, and it probably suffered an injury or irritation during the time of suckling, and from that time began to grow heterologously, a conversion to malignancy being the result. If the patient had not been subject to this point of weakness, it may very well be doubted if she would have had the sarcoma; and also if the tumor had been early removed, there would have been no sarcoma. Dr. Bennett opposes the teaching of some of the text-books that chronic mammary tumors have a tendency to shrink and disappear. His observation is that these chronic adenomata or adenofibromata do not shrink, to say nothing of their complete disappearance. Chronic indurations sometimes disappear during lactation, especially after a first parturition, but these are, in his opinion, not the true chronic tumor of the breast. In the latter, the tendency after parturition is invariably in the direction of growth rather than shrinkage, and toward malignancy rather than to remain *in statu quo*. The pathological probability is in favor of the less desirable result, in the case of these chronic and "benign" mammary growths. Their "benign" element is almost invariably compassed in a mere chronicity, longer or shorter, but danger is never absent.

MINOR PARAGRAPHS.

UNCLEANLINESS IN THE MAKING OF ICE-CREAM A SOURCE OF SICKNESS.

DR. WALTER KENT, of the Brooklyn Board of Health, has investigated a number of the ice-cream factories in that city, and has found that uncleanness is the rule rather than the exception in those places. Not a few of them were in filthy

cellars or basements, where there was the foulest of atmospheres. Often he saw that no pretense was made of the cleansing of any of the apparatus except "the immediate vessels" in which the cream was cooked. The floors were seldom cleanly, and seldom in such a condition that they could be cleaned. Suitable doors and windows were often wanting. Rubbish abounded and much mud in the unlighted corners. Although many "hands" are employed, they are generally of the unskilled variety, to whom disorder is congenial, and who are so "driven" that they have no time to clean up. Such filthy conditions, says Dr. Kent, suggest general carelessness in methods of working, and it is more than probable that material which by itself we should avoid is allowed to enter into the production of a food substance. Miscellaneous dirt and filthy surroundings, being favorable to the life of so many of the micro organisms of disease, should be interdicted in connection with ice cream manufacture. Considering also the danger of metallic poisoning from the use of imperfectly cleansed cans, perfect cleansing should be insisted upon by the inspectors of foods. Dr. Kent holds also that the ice-cream is kept on hand too long whenever the demand becomes light by reason of an unexpected change in the weather. This might not be an element of danger if the people who made the cream were careful, but when so much carelessness exists as was discovered and reported by Dr. Kent, it is probable that long keeping is one of the causes of "ice-cream poisoning." No examinations were made for tyrotoxin by Dr. Kent in the recent cases in Brooklyn, for the reason that the specimens brought to him were not in a sufficiently fresh condition.

PUDIC NEURECTOMY AS A REMEDY FOR MASTURBATION.

DR. J. S. EASTMAN publishes in the *Medical News* for August 12th the history of a patient, aged twenty-six, who had been a confirmed masturbator since her sixth year. Coition was without satisfaction and caused her pain. She had run the gamut of internal medication, suturing of the labia majora, electrocauterization of the parts, oophorectomy, and clitoridectomy, without relief to her nervous symptoms or to her desire for masturbation. Dr. Eastman, finding one side of the vulva more sensitive than the other, thought that a local paralysis would be desirable. He cut down upon the pudic nerve on the left side, and, finding it hypertrophied, dissected and removed a portion about three inches long. The wound healed promptly, the patient gained in weight, her symptoms disappeared, and a year and a half after the neurectomy she was still free from her vice of masturbation.

THE NATURE OF THE PHENOMENA OF HYPNOTISM.

At the last annual meeting of the British Medical Association a report presented by the Committee on Hypnotism was referred back to it for further examination and report. The *British Medical Journal* for July 29th publishes a résumé of the extended report of the committee, in which it is stated that the committee has satisfied itself of the genuineness of the hypnotic state, though no phenomena observed lent support to the theory of "animal magnetism." The test experiments showed that the condition was attended by mental and physical phenomena that differed widely in different cases. Among the mental phenomena are altered consciousness; temporary limitation of will-power; increased receptivity of suggestion from without, sometimes to the extent of producing passing delusions, illusions, and hallucinations; an exalted condition of the attention; and methypnotic suggestions. Among the physical phenomena are vascular changes (such as flushing

of the face and altered pulse-rate); deepening of the respirations; increased frequency of deglutition; slight muscular tremors; inability to control suggested movements; altered muscular sense; anæsthesia; modified power of muscular contraction; catalepsy; and often intense rigidity. The committee suggests that the term hypnotism is misleading, inasmuch as sleep, as ordinarily understood, is not necessarily present. It concludes that as a therapeutic agent hypnotism is frequently effective in relieving pain, procuring sleep, and alleviating many functional ailments. As to its permanent efficacy in the treatment of drunkenness, the evidence is encouraging but not conclusive. The therapeutic employment of hypnotism should be confined to qualified medical men. Dangers in the use of hypnotism may arise from want of knowledge, from carelessness or intentional abuse, or from the too frequent repetition of suggestions in unsuitable cases. Legal restrictions should prohibit the public exhibition of hypnotic phenomena.

THE ILL EFFECTS OF PHENAZONE, ACETANILIDE, AND PHENACETINE.

The *British Medical Journal* for July 29th publishes the report of a committee giving the results of an inquiry into the frequency and the importance of the ill effects alleged to attend the use of phenazone (antipyrine), acetanilide, and phenacetine as antipyretic and analgesic agents. The committee concludes that the frequency and importance of these ill effects have been considerably exaggerated. With due care, especially as regards the initial dosage, ill effects other than those connected with idiosyncrasy are extremely infrequent, of little or no importance, and not of such a character as to limit the usefulness of the drugs in any material way. This conclusion does not so fully apply to acetanilide, the action of which has frequently been followed by ill effects, though in the majority of such cases the dosage employed was too large.

HYSTERICAL AMAUROSIS CURED BY SUGGESTION.

DR. J. J. CHISOLM reports in the *Medical News* for August 12th the case of a patient in whom positive mental impressions promptly cured a case of hysterical blindness. She was a girl seventeen years old, who had blindness in one eye suddenly come on while she was at school. By careful examination it was determined that she was not blind, and she was given some pills that she was told would cure her in exactly three days. She was to report each day, at the same hour, at the physician's office, and on the third day she said she could not yet see. Looking at his watch, the physician said there was yet five minutes to wait for returning vision, and before the lapse of that period her vision returned. Another illustration of the "faith cure."

THE NORTH AMERICAN PRACTITIONER.

DR. JOHN H. HOLLISTER has been appointed to the editorship of that journal. He is well known among the medical editors of the country as having been the conductor of the *Journal of the American Medical Association*. He was the immediate predecessor of Dr. Culbertson, whose two years' service was closed this year by resignation.

HYPNOTISM.

The British Medical Association's special committee on hypnotism has made public a portion of the results of its investigation. It affirms the genuineness of the potency of hyp-

notism, and the necessity for the safeguarding of its employment. The use of hypnotic sleep should be restricted to physicians, and these should only exercise it upon female patients when the latter are in the presence of relatives. Hypnotism has been found serviceable in the relief of pain and of insomnia. Regarding its use in narcotic addiction or alcoholism, the case is still open for proof; it is not certain that it can be so used as to effect a cure.

A PECULIAR CASE OF SNEEZING CURED WITH ARSENIC.

In the July number of the *Calcutta Medical Reporter* Mr. D. Robertson, of the Government House Dispensary, reports the case of a Eurasian, twenty-two years old, who was suffering with distressing fits of sneezing, which came on every morning when he washed his face. The application of water to other parts of the body or to the face at other times of the day did not produce it. The morning seizures came on immediately on applying the water, whether hot or cold. The use of arsenic, in the form of Fowler's solution, five minims three times a day, gradually effected a cure.

TYPHUS FEVER AT CONEY ISLAND.

A MAN, employed at the Manhattan Beach Hotel, was recently found to be suffering from typhus fever. He was taken to the hospital on North Brothers Island. The period of his employment at the seaside dates back nearly a month, before which time, it is alleged, he was a resident of a country place in Pennsylvania, the name of which is not reported. The man's duties did not bring him into contact with the patrons of the hotel.

ITEMS, ETC.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending August 15, 1893:

DISEASES.	Week ending Aug. 8.		Week ending Aug. 15.	
	Cases.	Deaths.	Cases.	Deaths.
Typhus.....	0	0	1	0
Typhoid fever.....	27	4	30	3
Scarlet fever.....	42	6	43	1
Cerebro-spinal meningitis.....	10	7	0	0
Measles.....	161	9	124	4
Diphtheria.....	94	19	100	30
Small-pox.....	5	0	1	1

The Pan-American Medical Congress.—The provisional programmes are as follows:

Section in General Medicine.—Paper by Manuel Carmona y Valle, M. D., City of Mexico, Mexico (neither title nor abstract furnished); Formas del Impuladismo i Medico de reconvertes, by Francisco A. Risquez, Caracas, Venezuela (abstract); paper by E. L. Shurley, M. D., Detroit (neither title nor abstract furnished); paper by J. C. Wilson, M. D., Philadelphia (neither title nor abstract furnished); paper by Charles G. Stockton, M. D., Buffalo (neither title nor abstract furnished); paper by T. Peyre Porcher, M. D., Charleston (neither title nor abstract furnished); paper by J. H. Musser, M. D., Philadelphia (neither title nor abstract furnished); paper by George Dock, M. D., Ann Arbor (neither title nor abstract furnished); Cold Steel as an Antirheumatic, by W. K. Vance, M. D., Bristol, Tenn. (abstract); Cholera Asiatica—1892, by J. D. Burch, M. D., Aurora, Texas (abstract); Facts in Stethoscopic Percussion, by Henry Sewall, M. D., Denver, Col. (abstract); paper by W. C. Christopher, M. D., Chicago (neither title nor abstract furnished); A Study of Some Cases of Chronic Diabetes, by N. S. Davis, Jr., M. D., Chicago (abstract); paper by C. S. Bond, M. D., Richmond, Ind. (neither title nor abstract furnished); Typhoid, by W. C. Dabney, M. D., Uni-

versity of Virginia, Va. (abstract); A Case of Acromegalia in a Giant, by Woods Hutchinson, M. D., Des Moines, Iowa (abstract); paper by D. W. Prentiss, M. D., Washington, D. C. (neither title nor abstract furnished); paper by R. L. Miranda, M. D., New York (neither title nor abstract furnished); paper by William Osler, M. D., Baltimore (neither title nor abstract furnished); The Value of Rest as a Therapeutic Agent in Chronic Pulmonary Tuberculosis, by Carl von Ruck, M. D., Asheville, N. C. (abstract); A New Anaerobic Bacillus of Malignant Edema, by F. G. Noy, M. D., Ann Arbor (abstract); Progressive Pernicious Anemia, by Judson Daland, M. D., Philadelphia (abstract); On the Occurrence of a Form of Chronic Bright's Disease other than Typical Fibroid Kidney without Albuminuria, by D. D. Stewart, M. D., Philadelphia (abstract); De la Buba, by Dr. Luis Razetti and Dr. N. Guardia, Caracas, Venezuela (abstract); La folie chez le nègre, by J. B. Da Lacerda, M. D., Rio de Janeiro (abstract); La cause de la fièvre jaune, by J. B. Da Lacerda, M. D., Rio de Janeiro (abstract); A New Disease of the West Indies, by Cuthbert Brown, M. D., Barbados (abstract); The Bacteriology of Dengue Fever, by J. W. McLaughlin, M. D., Austin, Texas (abstract); The Culture of Anaerobic Bacteria, by F. G. Noy, M. D., Ann Arbor (abstract); Consideraciones sobre dos Casos de Anemia por Ankylostoma duodenale observados en el Hospital Victor Manuel de Lima, by J. B. Agnoli, M. D., Lima, Peru (abstract); A Contribution to the Study of Prolonged Intermittent Fever, by David Lobo, M. D., Caracas, Venezuela (abstract); The Nature of the Germicidal Constituent of the Blood Serum, by Victor C. Vaughn, M. D., Ann Arbor (abstract); On Vaso-motor Ataxia, by J. Solis-Cohen, M. D., Philadelphia (abstract); Recent Experiences in Croupous Pneumonia, with Observations on Treatment by Subcutaneous Injections of Saline Solutions, by R. F. Cunningham, M. D., Birmingham, Ala. (abstract not furnished); Cholera, its Diagnosis, Prognosis, and Treatment, by J. M. Hurley, M. D., San Bernardino, California (abstract not furnished); Colera Morbo Asiatico, by Santiago Hernandez, M. D., Santa Clara, Cuba (abstract); The Importance of Eliminating Pelvic Diseases in General Diagnosis, by Mary H. McLean, St. Louis (abstract); Clinical Notes on Amebic Dysentery, by H. A. West, M. D., Galveston, Texas (abstract); Some American Ideas about Chronic Diarrhea, by Ephraim Cutter, New York (abstract); Tratamento médico del vomito negro, by Segundo Bellver Mateo, Havana (abstract); The Principles of Immunity and Cure in the Infectious Diseases, by Victor C. Vaughn, M. D., Ann Arbor (formal address); Forced Respiration—Fell Method—A Plea for its General Adoption in Hospital and Naval Practice, by George E. Fell, Buffalo, (abstract).

Section in General Surgery.—The Treatment of Pott's Disease of the Spine, by A. B. Judson, M. D., New York (abstract); The Probable Cause of Limp in the First and Second Stages of Hip-joint Disease, by Harry M. Sherman, M. D., San Francisco (abstract); The Mechanical Treatment of Osteo-arthritis of the Knee, by Henry Ling Taylor, M. D., New York (abstract); paper by Dr. Bernardo Herrera, Caracas, Venezuela (neither title nor abstract furnished); paper by Dr. Juan M. Escolana, Caracas, Venezuela (neither title nor abstract furnished); Ununited Fracture, by Lilwellly Elliot, M. D., Washington, D. C. (abstract); Some Points in the Surgical Treatment of Appendicitis, by Augustus P. Clarke, M. D., Cambridge, Mass. (abstract); A Brief Splint Technology for Surgeons, by Edward A. Tracy, M. D., Boston (abstract); Reconstructive Surgery, by Thomas G. Maghee, M. D., Rawlins, Wyo. (abstract); Urethral Polypus in the Male, by R. Menocal, M. D., Havana (abstract); Simplicity in Surgery, by Robert W. Johnson, M. D., Baltimore (abstract); A Report of Four Cases of Brain Surgery, by Andrew J. McCosh, M. D., New York (abstract); Soudas y Bujras Gecacas del Dr. Castano, by Dr. Alberto Castano, Buenos Ayres, Argentine Republic (abstract and specimens); paper by Ignacio Placencia, M. D., Havana (title and abstract in hands of Literary Bureau); paper by Ignacio Placencia, M. D., Havana (title and abstract in hands of Literary Bureau); Tratamiento Quirúrgico de la Fiebre Amarilla, by Segundo B. Mateo, M. D., Havana (abstract); In what Class of Cases is Drainage required? by H. O. Marcy, M. D., Boston (abstract not furnished); Causation, Pathology, and Treatment of Carbuncle, by David W. Graham, M. D., Chicago (abstract not furnished); paper by Dr. Martín Herrera, Caracas, Venezuela (neither title nor abstract furnished); paper by Dr. Miguel A. Leco, Caracas, Venezuela (neither title nor abstract furnished); Improved

Long Traction Hip Splint with Proper Method of applying Counter-extension, by Henry Ling Taylor, M. D., New York (demonstration); Improved Apparatus for Pott's Disease, by Henry Ling Taylor, M. D., New York (demonstration); Apparatus for the Correction of Talipes Equino-varus and for the Retention of the Corrected Foot, by Henry Ling Taylor, M. D., New York (demonstration); Practical Orthopaedics, by Noble Smith, London, England (abstract not furnished); Observations on the Rotary Lateral Curvature of the Spine, with Special Reference to Etiology and Treatment, by Jacob Teschner, M. D., New York (abstract); Recumbence in the Treatment of Pott's Disease, by John C. Schapps, M. D., Brooklyn (abstract); Causes contributing to Failure in the Treatment of Hip-joint Disease, by A. M. Phelps, M. D., New York (abstract); Some Thomas's Splints, with Demonstrations of Principles, by John Ridlon, M. D., Chicago (demonstration); Orthopaedic Work done at the Vanderbilt Clinic of New York, from January, 1889, to June, 1893, by John Ridlon, M. D., Chicago (abstract not furnished); A Case of Acute Arthritis of the Hip of Infants, with some Remarks on the Etiology of the Affection, by Augustus Thorndyke, M. D., Boston (abstract); The Orthopaedic Treatment of Infantile Paralysis, by L. A. Weigel, M. D., Rochester, N. Y. (abstract); Gymnastic Apparatus for Scoliosis, by L. A. Weigel, M. D., Rochester (abstract not furnished); Practical Points in the Treatment of Hip Disease, by A. B. Judson, M. D., New York (abstract); The Technique of the Plaster Jacket, by Reginald H. Sayre, M. D., New York (demonstration); Club-hand, by Reginald H. Sayre, M. D., New York; Gastrostomy for the Relief of Esophageal Stricture, by Ernest Laplace, M. D., Philadelphia.

Section in Military Medicine and Surgery.—Laparotomy in Gunshot Wounds, by P. S. Conner, M. D., Cincinnati (abstract not furnished); paper by Hunter McGuire, M. D., Richmond (neither title nor abstract furnished); paper by Colonel Joseph R. Smith, Medical Director, Headquarters, Department of California, San Francisco, Cal. (neither title nor abstract furnished); paper by W. A. Hammond, M. D., Washington, D. C. (neither title nor abstract furnished); Are Projectiles from Portable Hand Weapons Sterilized by the Act of Firing? Can a Septic Bullet infect a Gunshot Wound? by Captain Louis A. La Garde, Chicago (abstract); The Place of Selection and Methods of Amputation, with Reference to the most Useful Artificial Appliances, by Stephen Smith, M. D., New York (abstract not furnished); paper by Brevet Lieutenant-Colonel A. A. Woodhull, Surgeon, U. S. A., Hot Springs, Ark. (title and abstract in hands of Literary Bureau); Personal Experience in the Results of Good and Bad Sanitation in the Confederate Army, by Bedford Brown, M. D., Alexandria, Va. (abstract); The Causes and Origin of Continued Fevers in Naval Service, by C. A. Siegfried, M. D., Surgeon, U. S. Navy, Newport, R. I. (abstract); paper by N. Senn, M. D., Chicago (neither title nor abstract furnished); paper by John Homans, M. D., Boston (neither title nor abstract furnished); Apresos de Campamento de Uso en Cuba por los Médicos Militares, by Dr. Felix Estrada y Cotoyra, Havana (abstract); Hospital Corps Drill by Detachment, under the command of Major Van R. Hoff, Surgeon, U. S. A.; Exhibition of a Field Hospital Complete, with Equipment now in use in the United States Army; First Aid to the Wounded and Transportation of the Wounded from the Battlefield and Field Hospitals (open discussion); Visit to the Army Medical Museum (a) Inspection of Collection; (b) Inspection of Library of the Surgeon General's Office.

Section in Obstetrics.—Address by Giles S. Mitchell, M. D., Executive President, Cincinnati; Maternity Hospitals and their Results, by Joseph Price, M. D., Philadelphia (abstract not furnished); The Axis-Traction Principle in Obstetrics, by Joseph Hoffman, M. D., Philadelphia (abstract not furnished); The Care of the Pregnant Woman in the First Half of Utero-gestation, by W. H. Baker, M. D., Boston (abstract not furnished); The Hemorrhages of Pregnancy and their Management, by J. O. Polak, M. D., Brooklyn (abstract); A Study of Placenta Previa, especially the Causes of the Hemorrhages, by Sarah Hackett Stevenson, M. D., Chicago (neither title nor abstract furnished); The Management of the Placenta in Operations for Ectopic Gestation, by D. Tod Gilliam, M. D., Columbus, O. (abstract); The State of Obstetrics in General Practice, by Eliza H. Root, M. D., Chicago (abstract); The Mechanism of Labor, by J. C. Rutherford, M. D., Providence, R. I. (ab-

tract); The Induction of Premature Labor, by J. H. W. Chestnut, M. D., Philadelphia (abstract); Aids to Easy Parturition, by A. J. T. Sannier, M. D., Chicago (abstract); Occipito-posterior Positions and their Management, by F. C. Fergusson, M. D., Indianapolis (neither title nor abstract received); The Therapeutic Application of Chloroform in Labor, by J. N. Upshur, M. D., Richmond (abstract); The Management of Some Cases of Difficult Labor, by W. H. Taylor, M. D., Cincinnati (abstract not furnished); Forceps Delivery, by James Campbell, M. D., Hartford, Conn. (abstract not furnished); The More Frequent Use of Forceps in the Multipara, by Lyman A. Berger, M. D., Kansas City, Mo. (abstract not furnished); The Use and Abuse of the Forceps, by W. Frank Haehnlen, M. D., Philadelphia (abstract not furnished); Symphysiotomy, by Henri Jacques Garrigues, M. D., New York (abstract); What has Surgery done for Modern Obstetrics? by Thomas Opie, M. D., Baltimore (abstract not furnished); Recent Surgical Advances and their Relation to Conservative Obstetrics, by W. Reynolds Wilson, M. D., Philadelphia (abstract); Puerperal Peri-uterine Inflammations, their Pathology and Treatment, by J. Foster Scott, M. D., Washington, D. C. (abstract not furnished); The Pathology and Treatment of Puerperal Infection, by Edward A. Ayers, M. D., New York (abstract); Infection of the Kidneys after Labor, by Barton Cooke Hirst, M. D., Philadelphia (abstract not furnished); Puerperal Eclampsia, by J. G. Cecil, M. D., Louisville (abstract not furnished); Puerperal Eclampsia, by Theophilus Parvin, M. D., Philadelphia (abstract not furnished); Induction of Labor and Accouchement Forcé in the Preventive Treatment of Eclampsia, by Charles Jewett, M. D., Brooklyn (abstract); Contribución al Estudio de la Septicemia Puerperal, by Dr. Antonia José Amadeo, Maunabo, Puerto Rico (abstract); A Study of Dystocia, by Dr. Salvador Garciadiego, Guadalajara, Mexico (abstract); A Method of Performing Rapid Manual Dilatation of the Os Uteri, and its Advantages in the Treatment of Placenta Prævia, by Philander A. Harris, M. D., Paterson, N. J. (abstract); Nota sobre la Expresión de la Vegiga en la Retención de Orina Post Partum, by Dr. Sebastian Cuervo Serrano, Espiritu Santo, Cuba (abstract); The Application of Graphics to the Fetal Heart Sounds, by Hugh Hamilton, M. D., Harrisburg, Pa. (abstract); Compresión Uterina, by Dr. José María de Ita, Puebla, Mexico (abstract).

Section in Gynecology and Abdominal Surgery.—The Value of Certain Methods of Surgical Treatment for Chronic Proctiditis of the Uterus, by Augustus P. Clarke, M. D., Cambridge, Mass. (abstract); Hysterectomy for Fibroids, Methods and Results, by Joseph Price, M. D., Philadelphia (abstract not furnished); The Treatment of Suppurative Disease of the Pelvic Organs, by H. J. Boldt, M. D., New York (abstract); The Significance of Endometritis and the Necessity for its Early Cure, by Joseph Tabor Johnson, M. D., Washington, D. C. (abstract); An Inquiry into the Etiology of Mental Disturbances following Operations upon the Pelvic Organs of Women, by George H. Rohé, M. D., Catonsville, Md. (abstract); Report of One Hundred Operations done for Serious Structural Disease of the Abdominal and Pelvic Organs in Women, by I. S. Stone, M. D., Washington, D. C. (abstract); Two Cases of Ectopic Gestation with Unusual Complications, Laparotomy and Recovery, by T. H. Hawkins, M. D., Denver, Col. (abstract not furnished); Ought Craniotomy to be Abolished? by W. H. Myers, M. D., Fort Wayne, Ind. (abstract not furnished); What I have Learned in the Surgery of the Gall-bladder, by Joseph Eastman, M. D., Indianapolis (abstract not furnished); Gynecological Treatment in Sterile Women—the Cause and Treatment, by De Saussure Ford, M. D., Augusta, Ga. (abstract); Drainage of Ovarian Cysts where the Adhesions are such that it is Impossible to remove the Sac, by A. Vander Veer, M. D., Albany (abstract); paper by H. A. Kelly, M. D., Baltimore (neither title nor abstract furnished); The Relation of Urinary Conditions to Gynecological Surgery, by Charles P. Noble, M. D., Philadelphia (abstract); Shortening of the Round Ligaments in Retro-position of the Uterus, by T. Johnson Alloway, M. D., Montreal (abstract); Total Extirpation of the Fibroid Uterus, by Florian Krug, M. D., New York (abstract not furnished); paper by J. Algernon Temple, M. D., Toronto (neither title nor abstract furnished); Vaginal Hysterectomy, by E. E. Montgomery, M. D., Philadelphia (abstract); The Surgical Treatment of Tubercular Peritonitis, by M. B. Ward, M. D., Topeka, Kan. (abstract); paper by B. E. Hadra, M. D., Galveston, Texas (neither title nor ab-

stract furnished); A Last Resort in the Operative Treatment of Hernia, by Robert T. Morris, M. D., New York (abstract not furnished); When Operation is Refused, what then? by George R. Dean, M. D., Spartanburgh, S. C. (abstract); paper by W. E. B. Davis, M. D., Birmingham, Ala. (neither title nor abstract furnished); Perineo-vaginal Restoration, by Edward W. Jenks, M. D., Detroit (abstract); paper by W. Gardner, M. D., Montreal (neither title nor abstract furnished); The Present Status of our Knowledge of the Pathology of Pelvic Inflammation, with Special Reference to the Treatment of Pelvic Abscess, by R. B. Maury, M. D., Memphis, Tenn. (abstract); paper by John R. Haynes, M. D., Los Angeles, Cal. (neither title nor abstract furnished); The Omentum and the Role it plays in Operative Work upon the Abdomen, by James F. W. Ross, M. D., Toronto (abstract not furnished); Hysterectomy: Indications and Technique, by J. M. Baldy, M. D., Philadelphia (abstract); Observations on Total Extirpation of the Uterus for Cancer, Based upon a Personal Experience with Thirty-two Cases, by Charles A. L. Reed, M. D., Cincinnati (abstract not furnished); Ectopic Pregnancy, by Joseph Hoffman, M. D., Philadelphia (abstract not furnished); paper by E. W. Davis, M. D., Philadelphia (neither title nor abstract furnished); After-treatment of Abdominal Section, by L. S. McMurtry, M. D., Louisville (abstract not furnished); The Technique of Total Extirpation of the Fibromatous Uterus, by George M. Edebohls, M. D., New York (abstract); The Intra-uterine Tampon, by Andrew F. Currier, M. D., New York (abstract); A Plea for the Value of Early Diagnosis and Prompt Electrical Treatment of Fibroid Tumors of the Uterus, by G. B. Massey, M. D., Philadelphia (abstract); The Co-ordination of the Muscles closing the Urethra, Vagina, and Rectum, and its Application to the Precise Diagnosis and Surgical Treatment of Injuries to the Pelvic Floor, by A. W. Abbott, M. D., Minneapolis (abstract); Estudio Clínico sobre las Heridas Penetrantes del Abdomen i Pecho, by Dr. Juan Manuel Escalana, Caracas, Venezuela (abstract); Cavernous Angioma of the Uterus (with specimen presented) removed per Hysterectomy Vaginale, by H. J. Boldt, M. D., New York (abstract); The Dorsal Decubitus after Confinements and Miscarriages is the Commonest Cause of Retroversion with Fixation, by A. Laphorne Smith, M. D., Montreal (abstract); Observaciones sobre un Caso de Preñez Extra-uterina (Tubaria Derecha) Operada en el Hospital de San Salvador por el Dr. José Antonio Delgado, by Dr. J. Antonio Delgado, Guatemala City, Guatemala (abstract); Notes pour l'histoire des fibromyomes utérines, by Dr. Nicolas San Juan, City of Mexico, Mexico (abstract); The Results of Vaginal Hysterectomy, by Andrew J. McCosh, M. D., New York (abstract); Apuntamientos para el Estudio Comparativo de la Pelvis Mexicana y Europea, y Consecuencias Prácticas agüeda Lugar la Especial Conformación de la Primera, by Dr. Manuel Gutiérrez y Tomas Noriega, City of Mexico, Mexico (abstract); Analysis and Deduction from my First One Hundred and Ten Laparotomies for Appendicitis, with Report of Experimental Investigation, by J. B. Murphy, M. D., Chicago (abstract); A Study based upon one Hundred Consecutive Cases of Removal of Diseased Uterine Appendages with Two Deaths, by R. Stansbury Sutton, M. D., Allegheny, Pa. (abstract not furnished); Do the Catamenia invariably appear Earlier in Hot than in Cold Climates? by J. H. O'Donnell, Winnipeg, Manitoba (abstract); Cura Radical de las Hernias, by Dr. Luis C. Maglioni, Buenos Ayres, Argentine Republic (abstract); The After-treatment of Coeliotomy Cases, with Special Reference to Shock and Septic Peritonitis, by Eugene Boise, M. D., Grand Rapids, Mich. (abstract); Habits of Posture a Cause of Deformity and Displacement of the Uterus, by Eliza M. Mosher, M. D., New York (abstract).

Section in Therapeutics.—Paper by Edward Randall, M. D., Galveston, Texas (neither title nor abstract furnished); The Treatment of Scarlet Fever by Chloral Hydrate, by James C. Wilson, M. D., Philadelphia (abstract); A Plea for Physiological Remedies, by Simon Baruch, M. D., New York (abstract); Treatment of Chronic Catarrh and Allied Conditions of Lowered Hydrochloric Acidity, by D. D. Stewart, M. D., Philadelphia (abstract); The Physiological Actions of Alcohol, by David Cerna, M. D., Galveston, Texas (abstract); The Treatment of Neurasthenia, with Special Reference to the Best Cure, by F. X. Dercum, M. D., Philadelphia (abstract); The Advantages of Amorphous Phosphorus over the Official Form, by E. I. Richardson, M. D., Philadelphia (abstract); Venesection in the Treatment of Engorgement and Dilatation

of the Right Side of the Heart, by I. E. Atkinson, M. D., Baltimore (abstract); The Use of Nitroglycerin in Arterio-sclerosis, by T. G. Ashton, Philadelphia (abstract); paper by Edw. Martin, M. D., Philadelphia (neither title nor abstract furnished); Formal Address, by Hobart A. Hare, M. D., Executive President, Philadelphia; The Philosophy of Therapeutics, by L. B. Anderson, M. D., Norfolk, Va. (abstract); The Antipyretic Action of Alcohol, by A. B. Simmons, M. D., and R. J. Winn, M. D., Savannah, Ga. (abstract); Some Views regarding the Philosophy of Drug Action, by J. W. McLaughlin, M. D., Austin, Texas (abstract); The Treatment of Leprosy, by Richard H. L. Bibb, M. D., Sattilo, Mexico (abstract not furnished); paper by Fernando Altamirano, M. D., City of Mexico, Mexico (neither title nor abstract furnished); The Clinical Import of Kummys, by J. Mount Bleyer, M. D., New York (abstract); The Treatment of Exophthalmic Goitre, based on Forty-five Consecutive Cases, by A. D. Rockwell, M. D., New York (abstract); Etude sur un moyen d'assurer l'efficacité du copoia dans la médication suppressive de la hémorrhagie uréthrale, by L. T. C. Lamothé, M. D., Port au Prince, Haiti (abstract); Action physiologique de quelques plantes brésiliennes de la famille des Menespermacees, by J. B. Da Lacerda, M. D., Rio de Janeiro (abstract); Une plante convulsivante du Brésil, by J. B. Da Lacerda, M. D., Rio de Janeiro (abstract); The Pathology and Treatment of Gout, by James Tyson, M. D., Philadelphia (abstract); Contribution to the Therapeutics of Yellow Fever, by Pedro Peñuelas, M. D., Havana (abstract); Some Points in the Treatment of Uric-acid Diathesis, by F. E. Stewart, M. D., Watkins, N. Y. (abstract); A Contribution to the Treatment of Diabetes Mellitus, by Solomon Solis-Cohen, M. D., Philadelphia (abstract); The Value of the Bath in some Sthenic Conditions, particularly Typhoid Fever, by Simon Baruch, M. D., New York (abstract); The Indications which should Govern the Employment of the Several Anæsthetics, by H. C. Wood, M. D., Philadelphia (abstract not furnished); Electricity, its Use in Medicine, by F. Schavoir, M. D., Stamford, Conn. (abstract).

Section in Anatomy.—Anomalies of the Larynx as seen by the Specialist, by W. T. Cathell, M. D., Baltimore (abstract); paper by T. Griswold Comstock, M. D., St. Louis (neither title nor abstract furnished); paper by R. B. Gilbert, M. D., Louisville (neither title nor abstract furnished); The Diaphragm, by H. E. McIntire, M. D., Hudson, Wis. (abstract not furnished); A Note on the Occurrence of the Scapulo-clavicular Muscle, by R. S. Moody, M. D., New Haven (abstract); Mallet Finger, by R. T. Morris, M. D., New York (abstract); The Laws of the Growth of the Cell applied to Human Anatomy, by Robert Reyburn, M. D., Washington, D. C. (abstract); paper by R. Winslow, M. D., Baltimore (neither title nor abstract furnished); On the Presence of Linguatula Rhinosia in the United States, by C. W. Stiles, Ph. D., Washington, D. C. (abstract); Nerve Anastomosis, by A. C. Bernays, M. D., St. Louis (abstract not furnished); paper by G. A. Burgham, M. D., Toronto; paper by E. B. Kenner, M. D., St. Louis; paper by T. J. Lee, M. D., Minneapolis; paper by C. S. Minot, M. D., Boston; paper by John C. Munro, M. D., Boston; paper by J. T. Newman, M. D., New Orleans; paper by G. A. Piersol, M. D., Philadelphia; paper by James B. Prichard, M. D., St. Louis (neither titles nor abstracts furnished); A Part of the Anatomy of the Velum Pendulum Palati, by T. F. Rumbold, M. D., San Francisco (abstract); paper by D. F. Rodgers, M. D., Topeka, Kan. (neither title nor abstract furnished); paper by W. R. Stokes, M. D., Baltimore (neither title nor abstract furnished); paper by Prof. A. H. Tuttle, University of Virginia, Va. (neither title nor abstract furnished); The Human Hand, by G. W. West, M. D., Washington, D. C. (abstract not furnished); paper by George W. Wilcox, M. D., Augusta, Ga.; paper by W. P. Wilson, M. D., Philadelphia; paper by Edwin Bentley, M. D., Little Rock, Ark.; paper by Henry C. Boeming, M. D., Philadelphia; paper by Elizabeth R. Bundy, M. D., Philadelphia; paper by E. F. Clapp, M. D., Iowa City; paper by J. W. Hartigan, M. D., Morgantown, W. Va.; paper by William Krauss, M. D., Memphis, Tenn.; paper by Rudolph Matas, M. D., New Orleans; paper by J. W. Perkins, M. D., Kansas City (neither titles nor abstracts furnished); The Surgical Anatomy of the Appendix Vermiformis with some Anatomical Abnormalities Observed, by R. H. Plummer, M. D., San Francisco (abstract not furnished); paper by E. S. Hems, M. D., Lebanon, O. (neither title nor abstract furnished); The Dissecting Room, by E. W. Holmes, M. D., Philadelphia (abstract); The Rela-

tions of the Heart and Lungs to the Anterior Chest wall, as determined by Composite Photographs, by Irving I. Haynes, M. D., New York (abstract); Bone an Organized Substance, by G. F. Koehler, M. D., Portland, Oregon (abstract); Craniometric Measurement of 500 Skulls in Relation to Aural Topographic Anatomy, by E. Alexander Randall, M. D., Philadelphia (abstract); A Case of Supernumerary Nipples, with Remarks upon and Literature of the Subject, by Albert Pick, M. D., Manchester, N. H. (abstract); On the Zona Radiata of the Telostean Ovary, by Jacob Reichard, M. D., Ann Arbor (abstract).

Section in Physiology.—American Physiology—Past, Present, and Future, by Isaac Ott, M. D., Executive President of the Section, Easton, Pa. (formal address); The Pathology of Yellow Fever, by Joseph Jones, M. D., New Orleans (abstract); The Effect of Lesions of Certain Parts of the Brain upon the Heat Processes, by E. T. Reichert, M. D., Philadelphia (abstract); Heat Mechanism, by Dr. Bartolemeo Baculo, Naples, Italy (abstract not furnished); The Globulocidal Action of Blood Serum, by W. S. Carter, M. D., Philadelphia (abstract); On the Absorption of Iron in the Animal Body, by A. B. MacAllum, M. D., Toronto (abstract); Sur les troubles fonctionnelles dues à la chaleur, by Dr. J. B. Da Lacerda, Rio de Janeiro (abstract); The Automatism of Nerve Centers, by Prof. Samuel Wolfe, Philadelphia (abstract); On the Proteolysis of Crystallized Phyto-globulin or Vitellin, by Prof. R. H. Chittenden, New Haven (abstract); The Innervation of the Venæ Portæ, by F. Mall, M. D., Chicago (abstract); The Physiological Bases of Therapeutic Action—An Experimental Inquiry, by Thomas J. Mays, M. D., Philadelphia (abstract); Some Observations on the Normal Growth and Muscular Development of the Human Body under Systematized Exercises, by Henry G. Beyer, M. D., Annapolis (abstract); "Conversazione" on Methods of Teaching and Demonstrating Physiological Subjects, by W. G. Thompson, M. D., New York (abstract); Hibernation and Allied States in Animals, by Wesley Mills, M. D., Montreal (abstract); Sobre el Numero de los Globulos Rojos, by Dr. José G. Hernandez, Caracas, Venezuela (abstract); La force musculaire chez les Indiens, by Dr. J. B. Da Lacerda, Rio de Janeiro (abstract); On the Respiratory Center in the Medulla Oblongata, by Prof. Dr. J. Gad, Berlin, Germany (abstract); The Analysis of the Gastric Juice for Some Diseases of the Stomach, by Hugh Hamilton, M. D., Harrisburg, Pa. (abstract); A Microscopical Study of the Living Nerve Cell during Stimulation, by C. F. Hodge, M. D., Hickory Ridge, Tenn. (abstract); Changes in Ganglion Cells from Birth to Death from Old Age, by C. F. Hodge, M. D., Hickory Ridge, Tenn. (abstract); paper, to follow Dr. E. T. Reichert's on The Effect of Lesions of Certain Parts of the Brain upon the Heat Processes, by Isaac Ott, M. D., Easton, Pa. (abstract).

Section in Diseases of Children.—The Most Successful Method of Treating Croup, by J. O'Dwyer, M. D., New York city (abstract not furnished); The Teaching of Hygiene in Colleges and Public Schools, by F. Forchheimer, M. D., Cincinnati (abstract not furnished); Clinical Aspects of Infant Feeding, by E. P. Davis, M. D., Philadelphia (abstract not furnished); Clinical Notes of Eruptive Fevers in Southern California, by W. A. Edwards, M. D., San Diego, Cal. (abstract not furnished); Infant Feeding, by T. M. Rotch, M. D., Boston (abstract not furnished); The Time and Mode of the Introduction of the Exotic Diseases of Children into America, by J. Lewis Smith, M. D., New York (abstract not furnished); Physical Training of Public School Children, by J. Gardner Smith, M. D., New York (abstract); Palmus, by L. C. Gray, New York (abstract not furnished); Enterocolitis in Intestinal Diseases of Children, by E. E. Graham, M. D., Philadelphia (abstract not furnished); The Bacteriological Diagnosis of Diphtheria, by H. C. Ernst, M. D., Boston (abstract); Aphasia in Children, by F. Peterson, M. D., New York (abstract not furnished); On Milk (no definite title), by Henry D. Chapin, M. D., New York (abstract not furnished); The Race Factor in Gastro-intestinal Disease, by J. W. Byers, M. D., Charlotte, N. C. (abstract); The Treatment of Empyema in Early Life, by A. Brothers, M. D., New York (abstract); A Contribution to the Knowledge of Acute Primitive Enterocolitis during Low Infancy, by Dr. Joaquin L. Duénas, Havana (abstract); paper by J. B. Deaver, M. D., Philadelphia (neither title nor abstract furnished); The Production of Cow's Milk designed for Infant Feeding, by Henry L. Coit, M. D., Newark, N. J. (abstract); The Proper Mode of Preventing and Treating Diphtheria, based on Recent Discoveries relating to its Etiology and Pathology, by J. Lewis Smith,

M. D., New York (abstract not furnished); The Normal Præcordia in Infancy and Childhood, by H. B. Whitney, M. D., Denver (abstract); Intestinal Parasites Observed in the Island of Puerto Rico, by Dr. Antonia Amadeo, Manabó, Puerto Rico (abstract); Immediate Percussion among Children, by Dr. Olinto, Porto Alegre, Brazil (abstract not furnished); The Feeding of Children in Cuba during Infancy, by Dr. Joaquín L. Dueñas, Havana (abstract); Pertussis as it exists in the Rocky Mountains, by John M. Keating, M. D., Colorado Springs (abstract not furnished); Types of Gastro-intestinal Disease Prevalent in New York, by Floyd M. Crandall, M. D., New York (abstract); The Insane Disorders of Childhood, by J. Madison Taylor, M. D., Philadelphia (abstract); Cirrhosis of the Liver in Children, by W. A. Edwards, M. D., San Diego, Cal. (abstract); The Artificial Feeding of Children in Mexico, by Dr. J. Ramon Icaza, City of Mexico, Mexico (abstract).

Section in Pathology.—Abscess of the Liver, by James E. Reeves, M. D., Chattanooga, Tenn. (abstract not furnished); Notes on Three Years' Work in the Pathological Laboratory of the Charity Hospital of New Orleans, by Henry Dickson Bruns, M. D., New Orleans (abstract); paper by W. Henry Welch, M. D., Baltimore (neither title nor abstract furnished); paper by W. T. Councilman, M. D., Boston (neither title nor abstract furnished); Influenza, by Ramon Gutiérrez, New York (abstract); A Bacteriological Observation on the Waters of the Harbor of Havana, by Dr. Acosta y Grande, Havana (abstract not furnished); The Pathological Histology of Yellow Fever, by Dr. Acosta y Grande, Havana (abstract not furnished); Investigations concerning Malaria, by Dr. Coronado y Madau, Havana (abstract not furnished); Bacteriological Studies in Havana, by Dr. Davalos, Havana (abstract not furnished); Investigations upon the Carbuncle in Cuba, by Dr. Coronado, Havana (abstract not furnished); Observations on the Anti-rabic Treatment of Pasteur, by Dr. Acosta, Havana (abstract); The Ætiology of Cancer, with Special Regard to the Protozoa Parasites of Cancer, by Allen J. Smith, M. D., Galveston, Texas (abstract); Contribution to the Study of Cancer, by Dr. Wernicke, Buenos Ayres, Argentine Republic (abstract not furnished); The Medical Geography of Porto Rico, by Dr. A. J. Amadeo, Maunabo, Porto Rico (abstract); The Yellow Fever of the Creoles and the Negroes, by Dr. A. J. Amadeo, Maunabo, Porto Rico (abstract); paper by E. O. Shakespeare, M. D., Philadelphia (neither title nor abstract furnished); paper on Yellow Fever (definite title not yet furnished), by Dr. C. Heineman, Vera Cruz, Mexico (abstract not furnished); Theories of Inflammation, by Dr. José Torres Matos, Havana (abstract); L'État de hyperexcitabilité du nerf phrénique dans le bérberi, by Dr. J. B. Da Lacerda, Rio de Janeiro (abstract); Paludismo, by Dr. Antonio José Amadeo, Maunabo, Porto Rico (abstract); Pathology at the Institution for Feeble-minded Children at Elwyn, Pa., by Henry W. Cattell, M. D., Philadelphia (abstract); The Epithelio-genetic Origin of Cancer, by Joseph McFarland, M. D., Philadelphia (abstract); Cancer, by Dr. Wernicke, Buenos Ayres, Argentine Republic (formal discussion, with Prof. Allen J. Smith as co-referee); Cancer, by Joshua M. Van Cott, M. D., Brooklyn (abstract not furnished); Cancer, by Joseph McFarland, M. D., Philadelphia (formal discussion); Yellow Fever, by Dr. Acosta y Grande, Havana (formal discussion, with Dr. A. J. Amadeo, of Porto Rico, as co-referee); Practical Demonstration of the Methods in Pathological Histology, by James E. Reeve, M. D., Chattanooga, Tenn. (demonstration); Practical Demonstration of the Methods in Photography applied to Pathology, by W. M. Gray, M. D., Army Medical Museum, Washington, D. C. (demonstration); Practical Demonstration of Methods in Bacteriology, by J. J. Kinyoun, M. D., U. S. Marine-Hospital Service, Washington, D. C. (demonstration); The Third Blood Corpuscle as a Pathological Product, by R. L. Watkins, M. D., New York (abstract not furnished); On Cholera, by Herman M. Biggs, M. D., New York (abstract not furnished); The Pathology of Pelvic Inflammatory Trouble, by Joseph Price, M. D., Philadelphia (abstract not furnished); paper by G. F. H. Nuttall, M. D., Baltimore (neither title nor abstract furnished); paper by W. Hughes, M. D., Philadelphia (neither title nor abstract furnished); paper by W. J. Carter, M. D., Philadelphia (neither title nor abstract furnished).

Section in Ophthalmology.—Formal address by Julian J. Chisolm, M. D., Executive President of the Section, Baltimore; Skin Grafting for Malignancy of the Eyelids and Orbit, by F. B. Tiffany, M. D., Kansas City (abstract); Further Experiences in Graduated Tenotomy, by Charles

Herman Thomas, M. D., Philadelphia (abstract in hands of Literary Bureau); A Case of Cysticercus of the Vitreous, by William Cheatham, M. D., Louisville (abstract not furnished); Spontaneous Replacement of a Detached Retina, by James Wallace, M. D., Philadelphia (abstract); A Clinical Study of Heterophoria, by Hiram Woods, M. D., Baltimore (abstract); Treatment of Six Cases of Traumatic Irido-cyclitis complicated with Cataract, by Robert L. Randolph, M. D., Baltimore (abstract); Homochronous Hereditary Optic-nerve Atrophy extending through Six Generations, by G. M. Gould, M. D., Philadelphia (abstract); Further Studies of the Cycloplegic Value of Homatropine and Cocaine Discs as a Substitute for Atropine, Duboisine, and Hyoscine, by Casey A. Wood, M. D., Chicago (abstract); An Analysis of Fifty Cases of Convergent Strabismus, by H. F. Hansell, M. D., Philadelphia (abstract); Gouty and Rheumatic Affections of the Eye, by W. Oliver Moore, M. D., New York (abstract not furnished); Some Experiences in Hemorrhagic Glaucoma, its Prognosis and Treatment, by S. D. Risley, M. D., Philadelphia (abstract); Suppurative Processes of the Vitreous, by J. F. Fulton, M. D., St. Paul (abstract not furnished); The Local Application of Bichloride of Mercury in Deep-seated Diseases of the Eye, by W. F. Mitendorf, M. D., New York (abstract); A Clinical Study of the Visual Field in Hemianopsia, by C. A. Oliver, M. D., Philadelphia (abstract); Glaucoma from Traumatic Causes, by Dr. E. Lopez, Havana (abstract not furnished); The Nomenclature of Blepharitis, by Dudley S. Reynolds, M. D., Louisville (abstract not furnished); A Comparison of the Eye of White with Colored Pupils in the Public Schools of Washington City, by E. O. Belt, M. D., Washington, D. C. (abstract); The Hygienic and Scientific Value of Examinations of the Eyes in the Schools, by B. Alexander Randall, M. D., Philadelphia (abstract); On Croupous Iritis, by Adolf Alt, M. D., St. Louis (abstract); Tratamiento del Triquiasis y Distiquiasis por Adelantamiento del Párpado Superior, by Dr. J. Santos Fernandez, Havana (abstract); Remarks on the Treatment of Heterophoria, by E. J. Gardiner, M. D., Chicago (abstract); Extra-ocular Melanosarcoma of the Orbit, by S. C. Ayres, M. D., Cincinnati (abstract); Orbital Tumors, by Walter B. Johnson, M. D., Paterson, N. J. (abstract); The Treatment of Opacities of the Vitreous Humor by Hypodermic Injections of Pilocarpine, by T. J. Tyner, M. D., Austin, Texas (abstract not furnished); Relaciones de la Oftalmometria con la Skiascopia, by Dr. Pedro Lagleyze, Buenos Ayres, Argentine (abstract); The Ætiology and Early Management of Glaucoma, by G. E. Dean, M. D., Scranton, Pa. (abstract not furnished); Acute Monocular Neuro-retinitis, with Cases, by B. L. Millikin, M. D., Cleveland (abstract not furnished); A Contribution to Refractive Errors, by J. C. Morgan, M. D., Philadelphia (abstract not furnished); The Necessity for Complete Suspension of Accommodation by Mydiatics in the Adjustment of Glasses, by C. C. Savage, M. D., Nashville (abstract not furnished); The Relation of Skiascopy to other Tests for the Determination of the Ocular Refraction, by H. V. Wurde-mann, M. D., Milwaukee (abstract); A Few Thoughts about Ophthalmometry, as to what the Javal Instrument will do, and what it will not, by Louis L. Lautenback, M. D., Philadelphia (abstract not furnished); Astigmatism following Cataract Extraction and other Sections of the Cornea, by Edward Jackson, M. D., Philadelphia (abstract); Refraction Anomalies of Artists, by J. C. Morgan, M. D., Philadelphia (abstract not furnished); Further Observations on the Eye of the Negro, by C. W. Kollock, M. D., Charleston (abstract not furnished); Exophthalmus Traumaticus, by L. F. Love, M. D., Philadelphia (abstract not furnished); Graduated and Complete Tenotomy for the Relief of Heterophoria, with a New Objective Test for Use during the Operation, by S. Lewis Ziegler, M. D., Philadelphia (abstract); Cataract Extraction with the Iris Retractor, by Francis Valk, M. D., New York.

Section in Laryngology and Rhinology.—Paper by Robert Levy, M. D., Denver (neither title nor abstract furnished); The Relation of Diseases of the Rectum to Nasal Catarrh, by W. John Harris, M. D., St. Louis (abstract); Electrolysis for the Relief of Certain Morbid Conditions of the Nasal Septum, by James E. Newcomb, M. D., New York (abstract not furnished); Myxosis of the Pharynx, by W. C. Glasgow, M. D., St. Louis (abstract); The Easiest and Most Practical Means of making Galvano-cauterics, especially to Turbinate Hypertrophies, by Arthur G. Hobbs, M. D., Atlanta, Ga.; paper by W. H. Daly, M. D., Pittsburgh (neither title nor abstract furnished); paper by A. C. Wolfe, M. D., Columbus, Ohio (neither title nor abstract furnished); The Use

of Sodium Formate in Laryngeal Disease, by E. L. Shurly, M. D., Detroit (abstract not furnished); paper by G. B. Lawason, M. D., New Orleans (neither title nor abstract furnished); The Utility of the Electro-cautery Snare, by H. W. Loeb, M. D., St. Louis (abstract); paper by Jonathan Wright, M. D., Brooklyn (neither title nor abstract furnished); paper by John N. Mackenzie, M. D., Baltimore (neither title nor abstract furnished); Reflex Epilepsy from Intranasal Disease, by John O. Roe, M. D., Rochester (abstract); paper by Charles H. Knight, M. D., New York (neither title nor abstract furnished); paper by Alexander MacCoy, M. D., Philadelphia (neither title nor abstract furnished); paper by J. C. Mulhall, M. D., St. Louis (neither title nor abstract furnished); A Case of Angioma of the Nasal Septum, by Frederick C. Cobb, M. D., Boston (abstract); A Case of Elongation of the Epiglottis Reduced by Operative Measures, by Price Brown, M. D., Toronto (abstract); paper by Dr. Edward O. Cleyer, Buenos Ayres, Argentine Republic (neither title nor abstract furnished); Some of the Throat Conditions observed in Gouty Subjects, by S. Solis-Cohen, M. D., Philadelphia (abstract); paper by C. E. Bean, M. D., St. Paul (neither title nor abstract furnished); paper by H. Holbrook Curtis, M. D., New York (neither title nor abstract furnished); The Ultimate Prognosis in Neglected Adenoid Hypertrophy, by D. Bryson Delavan, M. D., New York (abstract); Report of a Case of Myxo-sarcoma of the Nasal Cavity, by C. W. Richardson, M. D., Washington, D. C. (abstract); The Surgical Treatment of Empyema of the Maxillary Sinus, by Dr. Edward Obejero, Buenos Ayres, Argentine Republic (abstract not furnished); Report on Cases of Tubercular Laryngitis treated in Colorado Springs, by S. E. Solly, M. D., Colorado Springs (abstract); Sarcoma of the Naso-pharynx, with the Report of a Case, by James E. Logan, M. D., Kansas City (abstract); Alumnol in Diseases of the Throat and Nose, by J. Mount Bleyer, M. D., New York (abstract); Some Forms of Nasal Reflexes, with Report of Cases, by S. K. Merrick, M. D., Baltimore (abstract); Hysterical Aphonia and Deafness, by E. Fletcher Ingals, M. D., Chicago (abstract); Clinical Notes of Cases of Tubercular Ulceration of the Larynx treated by the Krauss Method at the Throat and Chest Clinic of the Emergency Hospital, by T. Morris Murray, M. D., Washington, D. C. (abstract); Indications and Opportunity for Opening the Mastoid Process, by Dr. Edward Obejero, Buenos Ayres, Argentine Republic (abstract not furnished); On the Treatment of Empyema, with Due Regard to Normal Pulmonary Contractibility, by Dan Milliken, M. D., Hamilton, Ohio (abstract).

Section in Otolg.—The Prevention of Deaf-mutism, by C. M. Hobby, M. D., Executive President of the Section, Iowa City, Ia. (formal address); Chronic Disease of the Middle Ear, its Prognosis and Surgical Treatment, by Albert H. Tuttle, M. D., Cambridge, Mass. (abstract); Otacoustic Treatment; its History and Results upon the Deaf and Deaf-mutes, by J. A. Maloney, M. D., Washington, D. C. (abstract); The Phonograph in the Treatment of Deafness, by Johnson Eliot, M. D., Washington, D. C. (abstract); Some Interesting Cases of Mastoid Disease, by S. MacCuen Smith, M. D., Philadelphia (abstract); Opening the Mastoid Cells in Acute Inflammatory Middle-ear Disease, by L. D. Brose, M. D., Evansville, Ind. (abstract); Adenoids: a Contributive Factor in Aural Affections, by M. D. Lederman, M. D., New York (abstract); Compressed Air, Vapors, and Sprays in the Treatment of the Middle Ear and Eustachian Tubes, by H. V. Würdeman, M. D., Milwaukee (abstract); The Present Condition of Otolg in Europe, by Laurence Turnbull, M. D., Philadelphia (abstract); Pathological Conditions following Piercing of the Lobules of the Ear, by Max Thorner, M. D., Secretary of the Section, Cincinnati (abstract); Craniometric Measurements of Five Hundred Skulls in Relation to Aural Topographic Anatomy, by B. Alex. Randall, M. D., Philadelphia (abstract); Description of a Focusing Ear Trumpet, by Edmund D. Spear, M. D., Boston (abstract in hands of Literary Bureau); The Modern Non-surgical Treatment of Chronic Purulent Inflammation of the Middle Ear, with Indications for Surgical Interference, by R. C. Hefebower, M. D., Cincinnati (abstract in hands of Literary Bureau); The Treatment of Suppurative Processes of the Attic, by J. F. Fulton, M. D., St. Paul; The Non-surgical Treatment of Attic Necrosis, by W. Cheatham, M. D., Louisville; Preventable Deafness, by C. S. Turnbull, M. D., Philadelphia; Contribution to the Study of Aural Syphilis, by Max Toepflitz, M. D., New York; On Localization of Sound, by C. Barck, M. D., St. Louis; Indications for the Mastoid Operation and the Prefer-

able Methods, by S. S. Bishop, M. D., Chicago; Description of a Middle-ear Powder Blower, by R. D. Barret, M. D., St. Louis.

Section in Dermatology and Syphilology.—American Dermatology, by A. H. Ohmann-Dumesnil, M. D., Executive President of the Section, St. Louis (formal address); Lupus, its Excision, with Reports of Cases, by R. Merrill Ricketts, M. D., Cincinnati (abstract); Glycosuria as an Additional Symptom in the Neurotic Origin of Dermatitic Herpetiformis, by J. M. Winfield, M. D., Brooklyn (abstract); A Statistical Record of nearly Five Thousand Cases of Smallpox, by W. M. Welch, M. D., Philadelphia (abstract); The Treatment of Diseases of the Nails, by J. V. Shoemaker, M. D., Philadelphia (abstract); Primary Dystrophies of the Skin, by E. Preble, M. D., Cleveland (abstract); Paper by G. Holsten, M. D., Brooklyn (neither title nor abstract furnished); Rhinophyma, by A. W. Gottheil, M. D., New York (abstract not furnished); Rhinophyma, by A. H. Ohmann-Dumesnil, M. D., St. Louis (abstract); Frambesia, "Yaws," by Dr. George Edmund Pierce, British West Indies (abstract); The Question of the Communicability of Leprosy, by Dr. Beaven Rake, Trinidad, West Indies (abstract); Some of the Rarer Tropic Lesions in Leprosy, by Dr. Beaven Rake, Trinidad, West Indies (abstract); Beriberi en el Cauca, by Dr. Evaristo Garcia, Cali, Cauca, Colombia (abstract); Lepra en el Cauca, by Dr. Evaristo Garcia and Dr. Adolfo Tenorio, Cali, Cauca, Colombia (abstract); El Carateo, by Dr. Juan N. Wallis and Dr. Alfredo Garces y Domingo, Arboleda, Colombia (abstract); A Case of Recurrent Pruritus, by A. H. Ohmann-Dumesnil, M. D., St. Louis (abstract); On the Ætiology of Eczema, by A. Ravogli, M. D., Cincinnati (abstract).

Section in Diseases of the Mind and Nervous System.—Formal Address, by C. H. Hughes, M. D., Executive President of the Section, St. Louis; The Garglized Nervous System and some of its Diseases, by C. K. Mills, M. D., Philadelphia (abstract); paper by William A. Hammond, M. D., Washington, D. C. (neither title nor abstract furnished); The Traumatic Psychoneurosis, its Relations to Paranoia, Epilepsy, and Paretic Dementia, by J. G. Kiernan, M. D., Chicago (abstract not furnished); paper by T. Diller, M. D., Pittsburgh (neither title nor abstract furnished); paper by E. C. Seguin, M. D., New York (neither title nor abstract furnished); The Urine in Sexual Neurasthenia, by C. L. Dana, M. D., New York (abstract not furnished); Suppurative Meningitis and Myelitis, with Exhibition of Specimens, by Græme M. Hammond, M. D., New York (abstract not furnished); The Disease of Inebriety and its Treatment, by T. D. Crothers, M. D., Hartford, Conn. (abstract); Chorea, by Charles Henry Brown, M. D., New York (abstract not furnished); A Study of the Temperature in Twenty-five Cases of General Paralysis of the Insane, by Frederick Peterson, M. D., New York (abstract not furnished); The Present Status of Infantile Cerebral Palsies, by Frederick Peterson, M. D., New York (abstract not furnished); The Successful Management of Inebriety without Secrecy in Therapeutics, by C. H. Hughes, M. D., St. Louis (abstract); Erotopathia: Morbid Erotism, by C. H. Hughes, M. D., St. Louis (abstract); The Medical Treatment of Insanity, by Edward C. Mann, Brooklyn (abstract not furnished); Address of Welcome (in Spanish), by W. A. Hammond, M. D., Washington, D. C.; Where the New-born Baby Learned to Suck, by C. A. F. Lindorme, M. D., Atlanta, Ga. (abstract); The Treatment of Nervous Diseases in Sanitariums, by J. K. King, M. D., Watkins, N. Y. (abstract); The Influence of Alcohol upon the Human Powers and Constitution, by T. L. Wright, M. D., Bellefontaine, O. (abstract not furnished); The Treatment of Cerebral Hemorrhage, by D. R. Brower, M. D., Chicago (abstract not furnished); Neuro-angeio Paralysis and its Relation to Paretic Dementia, by Frank C. Hoyt, M. D., Clarinda, Ia. (abstract not furnished); paper by S. Weir Mitchell, M. D., Philadelphia; paper by E. C. Spitzka, M. D., New York; paper by O. T. Sherman, M. D., Boston; Civil Service in American Hospitals for the Insane, by S. V. Clevenger, M. D., Chicago (abstract); La Renguera, by Dr. Daniel Gutierrez y Arango, Cali, Cauca, Colombia (abstract); Paralisis Espastica Cerebral de los Adultos, by Dr. Manuel Carmona y Valle, City of Mexico, Mexico (abstract); On the Prognosis of "Railway Spine," by F. X. Dercum, M. D., Philadelphia (abstract); The Nervous Symptoms of Storms, by Curran Pope, M. D., Louisville (abstract not furnished); A Peculiar Type of Vaso-motor Neurasthenia (the Pulsating Disease) with Report of and Operation for the Same, by C. L. Dana, M. D., New York (abstract); The Curability of Inebriety, by J. G. Reed, M. D., Elmwood

Place, Ohio (abstract); Nutrition against Stimulation, by W. H. Maxon, M. D., St. Louis (abstract).

Section in Hygiene, Climatology, and Demography.—The Climate of Jamaica, by Dr. J. C. Philippo, Kingston, Jamaica (abstract); Les mesures prophylactiques contre les épidémies, by Dr. J. B. Da Lacerda, Rio de Janeiro (abstract); Practical Measures in the Prevention of Tuberculosis, by Lawrence F. Flick, M. D., Philadelphia (abstract); Apuntes sobre la Patología del Departamento Fluvial de Loreto, by Dr. Leonidas Arendano, Lima, Peru (abstract); Ojeada Retrospectiva sobre la Organización de la Sanidad en los Ejércitos Españoles, by Dr. Felix Estrada y Cotoyra, Havana, Cuba (abstract); The Climate of Western North Carolina, with a Consideration of the Relative Value of High and Medium Altitudes in the Treatment of Pulmonary Tuberculosis, by Karl von Ruck, M. D., Asheville, N. C. (abstract); The Climate of the Santa Cruz Mountains, by James Henry Clark, M. D., Jamaica, W. I. (abstract); On the Early Detection and Seasonable Climatic and other Treatment of Phthisis, by Charles Denison, M. D., Denver (abstract not furnished); The Distribution of Disease by Isthmian Practice, or the Direct Responsibility of the Republic of Columbia, S. A., in the Burial and Disinterring of the Dead on the Isthmus of Panama, by Wolfred Nelson, M. D., New York (abstract); The Three Climates of Jamaica, B. W. I., Its Coast or Tropical, Temperate, and Mountain Climates, Jamaica, considered as a Winter Island for Health, by Wolfred Nelson, M. D., New York (abstract); A Brief Consideration of Elephantiasis Arabum as Observed in the Samoan Islands, by John C. Wise, M. D., Washington, D. C. (abstract); On the Climatology of Egypt, by Dr. Grant (Bey), Cairo, Egypt (abstract); The Hygiene and Demography of Jamaica, by Dr. James Cecil Philippo, Kingston, Jamaica (abstract); The Need of Research in Preventive Medicine, by J. M. Postle, M. D., Hinkley, Ill. (abstract); The Effect of Advanced Civilization on Disease, by W. J. Moody, M. D., Plainfield, Iowa (abstract); Necessary Laws that should be Enacted by the Several States by which Municipal Health Authorities may be enabled to Control Infectious Diseases (discussion); The Cause and Prevention of Diphtheria (discussion); The Limitation and Prophylaxis of Tuberculosis (discussion); The Role of Municipal Sanitation in the Limitation and Eradication of Yellow Fever (discussion); On the Climatology of Mesopotamia, by John Sundberg, M. D., U. S. Consul, Bagdad, Asiatic Turkey (abstract not furnished); On the Climatology of Puerto Rico, by Pedro José Salicrup, Secretary of the Section, New York (abstract not furnished); Formal Address, by Albert L. Gihon, M. D., Medical Director, United States Navy, Naval Hospital, Washington, D. C.

Section in Marine Hygiene and Quarantine.—Formal Address, by Walter Wyman, M. D., Executive President of the Section, Surgeon General of the United States Marine Hospital Service, Washington, D. C.; The Hygiene of Vessels, Commercial and Naval, including the Question of Ventilation, Heating, Sanitary Arrangements, the Disposal of Cargo so as to Facilitate Disinfection, Steam Disinfection, Food Supply, etc. (discussion opened by Dr. John J. Cassidy, Ontario, Canada) (abstract); Epidemic and Exotic Diseases Propagated by Shipping, What Diseases should be Quarantined. Responsibility of Nations for Epidemics; India for Cholera, South America for Yellow Fever. Can a Feasible Plan be Devised to totally Exterminate Cholera? International Intervention to Prevent the Propagation of Cholera or other Epidemic Diseases by Pilgrimages or Immigration (discussion opened by Wolfred Nelson, M. D., New York); International Uniformity in Quarantine Regulations (discussion opened by Dr. Juan J. Ulloa, San José, Costa Rica); The Medical Officers of Passenger Vessels; Methods for their Selection, Duties, etc. (discussion); The Vital Statistics of Seamen and Firemen. The Question of the Medical Examination of Crews Preparatory to Shipping (discussion); The Supervision of Vessels by Government Medical Inspectors at Ports of Arrival and Departure. Code of Rules for Handling an Epidemic Disease that Breaks out on Shipboard. Disinfection of Passengers and Crew during a Voyage. Location and Arrangement of Ship's Hospitals (discussion); Arrangement of Detail and Equipment of Quarantine Stations: *a*, Inspection Stations; *b*, Local Quarantine Stations; *c*, Refuge Stations. Methods for Handling Infected or Suspected Vessels. Interstate and Inland Quarantine. Sanitary Cordons; Camps of Refuge; Camps of Probation. Recent Improvements in Hospitals for Infectious Diseases. Railroad

Inspection and Quarantine. Length of Time Vessels should be Held in Quarantine. Conditions that should Determine Proclamation of Quarantine against a Country (discussion); Under what Requirements may Passenger Traffic be carried on between a Port Infected with Yellow Fever and a Southern Port of the United States during the Summer with the Least Obstruction to Such Traffic (discussion); What Merchandises should be Considered as Requiring Treatment if Shipped from a Port or Place infected with Cholera, Yellow Fever, or Small-pox? (discussion); Methods of Disinfection: *a*, Persons; *b*, Baggage; *c*, Cargoes; *d*, Vessels. Recent Improvements in Quarantine Appliances; Steam Chambers; Sulphur Furnaces. Liquid Sulphur Dioxide as a Disinfectant. Treatment of Ballast Water; Solid. What Time should an Infected Vessel be detained in Quarantine? *a*, for the Cholera; *b*, for Small-pox; *c*, for Typhus Fever; *d*, for Plague; *e*, for Yellow Fever. Methods of Disposal of the Bodies of those that Die while in Quarantine (discussion).

Section in Medical Pedagogy.—Medical Education in the United States, by J. Collins Warren, M. D., Executive President of the Section, Boston (formal address); A Consideration of the Position of Bacteriology in a Course of Medical Study; its Importance and Growth of Late Years, together with some Account of the Development of the Department in Harvard Medical School, by Harold C. Ernst, M. D., Boston (abstract); The Importance of Physiological Chemistry as a Part of Medical Education, by R. H. Chittenden, M. D., New Haven (abstract); A Contribution to the Study of Medical Education in the United States, by Bayard Holmes, M. D., Chicago (abstract); Methods of Medical Education, by Victor C. Vaughan, M. D., Ann Arbor (abstract); The Aims and Methods of Medical Education, by W. C. Dabney, M. D., University of Virginia, Va. (abstract); Methods of Instruction in Clinical Medicine, by F. C. Shattuck, M. D., Boston (abstract not furnished); The Latent Power of some American Medical Ideas, by Ephraim Cutter, M. D., New York (abstract); How to Teach the Cæsarean and Porro Operations in the Classroom, by E. Gustav Zinke, M. D., Cincinnati (demonstration); Demonstration of the Physiological Action of the Heart, by J. P. Sawyer, M. D., Cleveland (abstract not furnished); Demonstration of Methods of Teaching Surgery and Anatomy by Free-hand Drawing with Colored Crayons, by M. H. Richardson, M. D., Boston (abstract not furnished); The Relation of Biology to Medical Education, by W. T. Sedgwick, M. D., Boston (abstract not furnished); The Status of the "Preceptor" in Modern Medical Education (informal discussion); The Proper Position of the Medical Classics in the Modern Medical Curriculum (informal discussion); Which of the Collateral Sciences ought to be Eliminated from the Medical Curriculum, and which of them ought to be Embraced in the Required Preliminary Studies? (informal discussion); On the Feasibility of Arranging a practically Uniform Course of Medical Instruction and Requirements in the Various American Countries and Colonies (informal discussion to be participated in more particularly by the official delegates of the various governments and of the various medical schools).

Section in Medical Jurisprudence.—Medical Jurisprudence in its Relations to Dipomania, by Edward C. Mann, M. D., Brooklyn (abstract not furnished); La Antropología Criminal de Puerto Rico, by Dr. José Rodríguez Castro, Puerto Rico (abstract); The Present Status of Criminal Anthropology, by G. Frank Lydston, M. D., Chicago (abstract); Hypnotism: does it menace Public Weal? by Ferd. C. Valentine, M. D., New York (abstract); The Doctor in Court, by D. R. Wallace, M. D., Terrell, Texas (abstract not furnished); The Medico-legal Aspect of Hypnotism (discussion); The Question of Responsibility in the Extirpation of the Uterine Appendages in the Insane and in Minors (discussion); The Legal Aspect of Abdominal Section for Penetrating Wounds of the Abdomen (discussion); Medical Jurisprudence: its Aims, Importance, Status, and Demands for Higher Recognition and Increased Facilities for Instruction by our Institutions of Learning devoted to fitting our Young Men for the Professions of Law and Medicine, by A. Garcelon, M. D., Executive President, Lewiston, Me. (formal address).

Section in Railway Surgery.—Formal address, by C. W. P. Brock, M. D., Executive President of the Section, Richmond; Railway Surgery as a Branch of the Surgical Art, by E. R. Lewis, M. D., Kansas City (abstract); The Nose and Throat Service of the Missouri Pacific Hospital for 1892, by Hannu W. Loeb, M. D., St. Louis (abstract); The

History of Railway Surgical Organization, by C. B. Stemen, M. D., Fort Wayne, Ind. (abstract); Hot Water in Contusion of the Bones of the Foot and Ankle, by G. Chaffee, M. D., Brooklyn (abstract not furnished); Excision of the Shaft of the Femur following Pathological Fracture, by A. J. Mullen, Jr., M. D., Michigan City, Ind. (abstract not furnished); Implantation of Senn's Decalcified Bone; Recovery, by B. F. Wilson, M. D., Slater, Mo. (abstract not furnished); The Essential Elements of Ideal Surgery, by B. F. Wilson, M. D., Slater, Mo. (abstract not furnished); paper by T. C. Kennedy, M. D., Shelbyville, Ind. (neither title nor abstract furnished); paper by J. N. Warren, M. D., Sioux City, Iowa (neither title nor abstract furnished); The Torsion of Arteries for the Arrest of Hemorrhage, by J. B. Murdoch, M. D., Pittsburgh (abstract).

The William F. Jenks Memorial Prize.—The third triennial prize of five hundred dollars, under the deed of trust of Mrs. William F. Jenks, will be awarded to the author of the best essay on Infant Mortality during Labor, and its Prevention. The conditions annexed by the founder of this prize are, that the "prize or award must always be for some subject connected with obstetrics, or the diseases of women or the diseases of children"; and that "the trustees, under this deed for the time being, can, in their discretion, publish the successful essay, or any paper written upon any subject for which they may offer a reward, provided the income in their hands may, in their judgment, be sufficient for that purpose, and the essay or paper be considered by them worthy of publication. If published, the distribution of said essay shall be entirely under the control of said trustees. In case they do not publish the said essay or paper, it shall be the property of the College of Physicians of Philadelphia." The prize is open for competition to the whole world, but the essay must be the production of a single person. The essay, which must be written in the English language, or, if in a foreign language, accompanied by an English translation, should be sent to the College of Physicians of Philadelphia, Pennsylvania, U. S. A., before January 1, 1895, addressed to Horace Y. Evans, M. D., Chairman of the William F. Jenks Prize Committee. Each essay must be typewritten, distinguished by a motto, and accompanied by a sealed envelope bearing the same motto and containing the name and address of the writer. No envelope will be opened except that which accompanies the successful essay. The committee will return the unsuccessful essays if reclaimed by their respective writers, or their agents within one year. The committee reserves the right not to make an award if no essay submitted is considered worthy of the prize.

The Eleventh International Medical Congress.—Regarding the postponement of the meeting, the executive committee says: "In consequence of the sanitary condition of several of the European states which prevents their medical men leaving home, and following the advice of many of the most prominent scientists, both Italian and foreign, the executive committee of the congress has decided by a large majority to postpone the meeting till April, 1894. The exact date of the inauguration will soon be fixed."

Proceedings of Societies.

AMERICAN NEUROLOGICAL ASSOCIATION.

Nineteenth Annual Meeting, held at Long Branch, N. J., on Tuesday, Wednesday, and Thursday, July 25, 26, and 27, 1893.

The President, Dr. HENRY M. LYMAN, of Chicago, in the Chair.

(Concluded from page 192.)

A New Pododynamometer.—Dr. WILLIAM C. KRAUSS, of Buffalo, exhibited an apparatus consisting of a wide, heavy belt, its inner surface padded so that its adjustment around the

wast would not be uncomfortable. A heavy webbing was looped through the belt, passing over the shoulders, which helped to retain the belt in position. A common dynamometer was connected with the belt by means of a strong adjustable strap, permitting it to be lengthened or shortened according to the stature of the patient. Connected with the dynamometer was a stirrup, the base of which was padded for receiving the foot. Pressure exerted upon the stirrup would be registered upon the dial of the dynamometer and the exact strength of the extensors of the leg could thus be ascertained. The apparatus could be applied in either the standing or the recumbent posture. The leg should be flexed to about ninety degrees at the knee. To tell the strength of the calf muscles the strap should be lengthened and the foot flexed upon the leg.

Infectious Endocarditis with General Septicæmia, complicated with Multiple Neuritis.—This paper was a joint communication by Dr. JAMES H. LLOYD and Dr. DAVID RIESMAN, of Philadelphia. It was founded on the report of two cases.

The first case was in a man who was admitted to hospital with a typhoid type of fever which had continued for three months, and was complicated with multiple neuritis. The diagnosis of typhoid fever was excluded. The neuritis was irregularly distributed. An aortic regurgitant murmur, with water-hammer pulse, gradually developed, and later a purpuric eruption appeared. A diagnosis was made of infectious endocarditis with secondary septic neuritis. At the post-mortem immense vegetations were found on the aortic valves, with infarcts in the spleen and in one kidney. Sections of the spinal cord and nerves were shown, exhibiting slight posterior sclerosis in the cord and extensive inflammation in the nerves.

The second case, also in a man, simulated typhoid fever, with the yellow-colored stools. At the post-mortem multiple abscesses in the brain, a large embolus in the left brachial artery, and an infarct in one kidney were found, dependent upon a giant growth of vegetations as large as a pullet's egg attached to the inner coat of the aorta, overhanging the orifices of the innominate, carotid, and subclavian arteries.

Dr. DANA regarded the septic origin of neuritis as of much importance. He cited the case of a young man with symptoms of rheumatism that did not respond to antirheumatic medication. Pyelitis developed in two or three weeks, followed by multiple neuritis affecting all the extremities. It was well known that multiple neuritis in this country was most frequently due to alcohol, and not of microbic origin. These forms of neuritis had a different clinical history. Some cases had begun with a history of multiple neuritis and had then shown symptoms of locomotor ataxia or other spinal-cord affection. There was a class of cases where the neuritis extended and ultimately involved the cord.

Dr. DEBUCUM agreed with Dr. Dana and believed posterior sclerosis occasionally followed multiple neuritis. He asked if septic symptoms had preceded the neuritis in Dr. Lloyd's case with a history of alcoholism, to which Dr. Lloyd answered Yes.

Tumor of the Angular Gyrus.—Dr. G. L. WALTON, of Boston, reported a case of tumor involving the angular gyrus and extending into the temporal, occipital, and parietal regions. The symptoms were temporal and occipital headache, vomiting, paralysis of the left abductors from pressure, double optic neuritis, hemianopsia, word-blindness, aphasia, and word-deafness. An operation was attempted by Dr. Richardson, of Boston. The tumor, however, proved too large and diffuse for removal. The patient lived two months, with comparative relief of pressure symptoms, including the abductors paralysis. Toward the end the right hand and arm became somewhat paretic. The autopsy showed the growth to be a glioma.

Dr. SEGGIN suggested that the ocular symptoms were probably not due so much to lesion of the angular gyrus as to involvement of the fibers of the fasciculus opticus which lie immediately under it. The lesion, being rather deeply placed, must necessarily involve the white fasciculi.

Dr. WALTON agreed with Dr. Seggin that the hemianopsia was due to affection of the optic radiations on their way to the occipital lobe. The early appearance of mind-blindness, together with red spots in the field of vision, suggested early cortical irritation in the region of the angular gyrus. If the symptom mind-blindness was considered due to an affection of association fibers, we were justified in assuming the association fibers implicated to be those running to the angular gyrus.

Congenital Cerebral Hemiplegia.—Dr. E. D. FISHER, of New York, read the history of a case of infantile cerebral hemiplegia of congenital origin. The symptoms were a complete right hemiplegia with marked atrophy and exaggerated reflexes, epilepsy, and imbecility. The cranial measurements showed morbid deficiency in the bicaudicular diameter and facial length. At the autopsy the left hemisphere was found much atrophied. The right cerebellar hemisphere was also atrophied. The microscopical specimens showed a decrease in the number of cortex cells, but those present were not much diminished in size. There was some loss of acuteness of the angles of the cells, but little pigmentary or granular change. The cord was but slightly affected. He believed that this would seem to show that in some cases there might be a fair amount of normal cerebral structure even when there was such pronounced cerebral disease.

Dr. SACHS said that in the cases in which motor areas presented developmental defect, degeneration did not necessarily occur.

Lesion of the Thalamus and Internal Capsule.—Dr. CHARLES K. MILLS, of Philadelphia, contributed the notes of a case in which there was a lesion of the thalamus and internal capsule. The patient had an apoplectic attack in 1877 and died in 1892. The symptomatology of the case summarized was: Hemianesthesia; paresis with contractures, not marked; and inability to recognize the position of the affected limbs. Hemianopsia and all affections of the special senses were absent, as were also athetoid and choreoid movements. The autopsy showed a hemorrhagic cyst which had destroyed about two thirds of the substance of the thalamus, including the entire external tubercle, and a large portion of the pulvinar. The anterior extremity and the internal and inferior surfaces of the thalamus were intact. The lesion had invaded the posterior arm of the capsule to a slight extent.

Tumor of the Optic Thalamus.—Dr. WHARTON SINKLER, of Philadelphia, read a paper on this subject, and presented the specimen from a case, with the following history: The patient was an unmarried woman, forty-six years of age, who was in excellent health up to January, 1893. Her first symptoms were somnolence and loss of mental vigor. Her manner was indifferent and listless. In April there was some aphasia and subsequent paresis of the right side of the face, with unsteadiness of gait and awkwardness in the use of the right hand. When she was first seen by him there were marked paralysis and partial anesthesia of the right side of the face, but there was no impairment of sensation of the arm or leg. There was decided mental hebetude, but no loss of memory. She could not walk, on account of unsteadiness. The knee-jerks were exaggerated. The temperature was subnormal and the pulse from 48 to 60. The pupils responded to light and accommodation. There was no nystagmus, hemianopsia, or change in the fundus oculi. The symptoms increased in severity, the temperature rose rapidly, and the patient died on May 25th. There had been no convul-

sions. The post-mortem showed the skull and membranes healthy. The cortex was normal in color and consistence. The left optic thalamus was the seat of a growth as large as a hen's egg, which encroached upon the corpus striatum and the posterior part of the internal capsule. The tumor had not been examined microscopically, but was probably a fibroma. The points of interest were the hysterical symptoms which were present at the onset, the fact that the anesthesia was confined to the face, and the question which arose as to the possibility of operation.

These two papers were discussed together.

Dr. DANA had had two cases—one with tumor and the other with softening in that region. Somnolence was a prominent symptom. The phenomenon of somnolence was characteristic where the posterior portion of the optic thalamus and the neighborhood of the corpora quadrigemina were involved.

Dr. SEGGIN had observed a patient who probably had a tumor in this locality with somnolence, which was increased by the use of iodide of potassium. He asked if such effect of the iodide had been observed by any of the members present.

Dr. DANA was familiar with a case where the iodide had acted as a hypnotic.

Dr. GRAY had noticed that the iodide had produced somnolence in a case of cerebro-spinal meningitis.

Dr. LESZYNSKY thought that the iodide only acted indirectly as a hypnotic by relieving the pains of syphilis.

Dr. SINKLER remarked that in his case the somnolence had diminished after the administration of the iodide.

The Localizing Value of Aphasia.—Dr. GEORGE J. PRESTON, of Baltimore, read a paper upon this subject, and called attention to the fact that aphasia had hardly commanded its proper place in the domain of cerebral localization. The centers for the speech processes and the visual and auditory centers were described. In connection with word-blindness, two cases of hemianopsia were related, one with autopsy, in which there had been no word-blindness, as might have been expected. A case of mixed aphasia was related and the brain exhibited. The case had shown absolute motor aphasia, together with word-blindness, and yet the lesion was confined to the third frontal convolution, the occipital cortex showing no disease. The general value of speech disturbance as an aid to localization, especially in disease or injury of the brain, was discussed. A case was reported in which there had been general speech disturbance, with distinct mental symptoms, and the patient was at times maniacal. Upon the strength of the general disturbance of the speech processes, the skull was trephined over Broca's region and the lower surface of the dura found covered with blood. This case was mentioned to show how valuable speech disturbances might be in diagnosis, although very general in nature and not belonging to any recognized variety of aphasia.

Spinal Neurasthenia.—Dr. LEONARD WEBER, of New York, presented a contribution upon this subject. He objected to any single plan of treatment as too much in the nature of routine and not likely to be of permanent service to the patient, while a proper combination of the well-known methods based upon careful individualization was apt to be of greater benefit. In the grave forms of neurasthenia caused by mental and physical overwork, the prognosis so far had not been good, even as to relative recovery. If the reports could be trusted, it would seem that we had in hypnotic suggestion a remedy of extraordinary power in some of these cases. In conclusion, he related the history of some cases of severe neurasthenia brought about by protracted mercurial inunction and another caused by the prolonged daily use of small doses of Carlsbad salts. Both patients had recovered at the end of about a year.

Observations in a Case of Myxœdema.—Dr. WILLIAM C. KRAUSS, of Buffalo, read a paper with this title. He reported a case of myxœdema in a woman fifty-three years old, whose mother had been afflicted with similar symptoms. The patient had always been in good health up to her forty-sixth year, although she had never perspired, and the secretions, such as the saliva, nasal mucus, and milk, had always been scanty. Following upon an accident, her face, body, and extremities became swollen, her hair suddenly disappeared from all parts of the body, and she was troubled with severe pains, especially through the temples, and a tired, "all-gone" feeling incapacitating her for all kinds of manual labor. She further complained of a feeling of coldness even in midsummer. Her hands were dry, harsh, and scaly, her face was waxy, and her eyes were puffy and swollen. Her temperature ranged from 95.4° to 97.4° F. Her pulse, soft, regular, and uniform, varied from 81 to 88. The œdema-like swelling did not pit on pressure. The urine was normal. The only drug that acted beneficially was perchloride of iron. The author experimented with the thyroid glands of sheep, feeding her for six weeks, but could detect no improvement whatever. Another case seen in consultation was being treated with desiccated thyroids, also without benefit.

Simulation in Traumatic Nervous Diseases.—Dr. PHILIP COOMBS KNAPP, of Boston, in a paper with this title, said that although many men would simulate disease if it was to their advantage, we rarely found successful simulation of the various traumatic nervous affections. Until recently few cases had been reported by neurologists; most of the old cases had been reported by general practitioners whose knowledge of nervous diseases was limited. In non-traumatic hysteria and neurasthenia we saw many reasons which would lead us to judge that the symptoms did not really exist. Many persons unjustly accused the victims of these diseases of pretending to be ill, when really the malady was a serious one. Contraction of the visual field, anesthesia, tremor, disturbances of the reflexes, circulatory disturbances, and Mannkopf's symptom were to be regarded as important objective signs. Few simulators could have intelligence enough to withstand a searching examination by a skilled neurologist. Furthermore, a man could keep his attention fixed on any subject only for a very brief time, and if he must be prepared to defend his simulation of half a dozen different symptoms, he would inevitably be tripped up by unexpected tests applied when his attention was diverted.

Three cases were cited in which the defense had maintained that there was simulation, but in every case objective evidence had proved the reality of the disease. Out of fifty cases where claims for damages had been brought forward, only two could be regarded as cases of simulation and few as cases of exaggeration, and in most of these there had been little reason to suppose there was any deliberate attempt at fraud.

Dr. MILLS believed absolute simulation very infrequent. The cumulative exaggeration of symptoms was comparatively frequent, however. A few people could simulate a type of insanity or traumatic neurosis, but could not easily simulate all the symptoms and signs. He was in favor of the convex-lens test for amblyopia, instead of prisms. He did not consider malingering of common occurrence.

Dr. GRAY thought many persons supposed to be simulating were simply offering to the trained eye symptoms indicative of possible simulation. He related a case of traumatic neurasthenia cured by $\frac{1}{2}$ of a grain of atropine taken for two days.

Dr. FIELD considered simulation rare. Gross exaggeration was common in these cases. In almost all there was some exaggeration of the symptoms.

Dr. LLOYD regarded the symptoms of traumatic neurasthenia as nothing but the interparoxysmal symptoms of hysteria. Be-

cause a man became affected with hysteria after an accident there was no reason to believe that he must be a simulator.

Dr. SEGUIN said the influence of the attending physician was often pernicious to the patient. He might not actually coach him, but he suggested. Some patients took advantage of a pre-existing morbid affection. The absence of treatment was responsible for a continuance of the symptoms of traumatic nervous affections. We should be allowed to examine these persons unexpectedly and thoroughly, and not when sympathetic physicians or counsel were present. He protested against Dr. Lloyd's remarks about the unity of hysteria and traumatic neurasthenia.

Dr. KNAPP said that he saw cases with minor exaggeration, in contrast to Dr. Field's cases of the grossest exaggeration. He agreed with Dr. Seguin regarding the absence of treatment, but he had had a number of cases where treatment had been early and properly instituted.

Nigrosin as a Stain.—Dr. SEGUIN exhibited a specimen stained with a 1-to-2,000 solution of nigrosin—a method he had used years ago, but neglected to publish. One of the advantages was that specimens might be safely left in the solution for twenty-four hours.

The Microbic Origin of Chorea.—Dr. C. L. DANA, of New York, read the history of a case of chorea, and an account of the autopsy. The patient, a man of twenty-six, had had chorea since the age of fifteen. The attacks came exactly like those of the ordinary chorea of Sydenham. At first there were intermissions, but the disease finally became chronic. The spasmodic movements were general and violent. There was no heart disease or rheumatism. The patient died from exhaustion. The post-mortem showed macroscopically a conspicuous chronic leptomenigitis involving the vertex of the brain. Microscopically, this was found to be mainly a proliferation process, without exudation or much cell infiltration. In the superficial layer of the cortex there was cellular infiltration with degenerative changes. At this point a diplococcus was found. Full details were given of this by Dr. Brooks, the bacteriologist. The micro-organisms were found only in the deep layer of the pia and the superficial part of the cortex. In addition, there were found peculiar hyaline bodies in the three outer layers of the cortex and less numerous in the basal ganglia. There were evidences of meningeal irritation, vascular disease (arteritis), and nerve-root irritation in the medulla and upper part of the cord. The lower part of the cord was not examined.

Election of Members.—The following-named gentlemen were elected to active membership: Dr. Brower, of Chicago, Dr. Burr, of Philadelphia, and Dr. Diller, of Pittsburgh. Dr. Arnold Pick, of Prague, was elected an associate member.

Papers Read by Title.—The Genesis of Hallucination, Illusion, and Delusion, by Dr. H. A. Tomlinson, of St. Peter, Minn.; The Diagnosis of General Paresis, by Dr. L. C. Gray, of New York; A Report of Two Cases of Friedreich's Disease, by Dr. Frank R. Fry, of St. Louis; The Metapore, or Foramen of Magendie, in Man and in the Orang, by Dr. Burt G. Wilder, of Ithaca, N. Y.; Observations on the Relation of Chorea to Rheumatism, by Dr. C. Eugene Riggs, of St. Paul; Experiences in the Use of Testiculin and Cerebrin, by Dr. J. J. Putnam, of Boston; Peripheral Paralysis after Surgical Operations, by Dr. V. P. Gibney, of New York; and Traumatic Brachial-plexus Paralysis in Infants, by Dr. W. M. Leszynsky, of New York.

Election of Officers.—The officers elected for the ensuing year were: President, Dr. B. Sachs, of New York; vice-presidents, Dr. F. X. Dercum, of Philadelphia, and Dr. P. C. Knapp, of Boston; secretary and treasurer, Dr. G. M. Hammond, of New York; counselors, Dr. E. C. Seguin, of New York, and Dr. J. H. Lloyd, of Philadelphia.

Book Notices.

A Contribution to the Pathology of the Vermiform Appendix.

By T. N. KELNACK, M. D. London: H. K. Lewis, 1893.

This monograph was presented to the Victoria University as a dissertation for the degree of doctor of medicine, and it embodies the main results of an extended investigation into a number of points connected with the pathology of the cæcal appendage.

The author finds that variations in the length of the appendix are independent of sex, age, height of body, and variations in size of the cæcum or length of the intestine; so also there is no fixed standard for the size of the appendix or of its lumen. Both he and other observers agree that it presents the greatest variety in its situation, excluding, of course, external and internal hernia of the appendix.

There are two interesting sections on cystic dilatation of the appendix and on abnormal substances that the appendix may contain.

The author mentions the varieties of inflammation of the appendix recognized by different observers, and he tabulates six varieties: simple, perforative, recurrent, tubercular, typhoid, and actinomycotic. He objects to the term "catarrhal" being employed to designate simple inflammation. He subdivides perforative inflammation into that with diffuse peritonitis, that with localized peritonitis, and that with extraperitoneal supuration. Each of these varieties is carefully considered in a separate chapter.

He holds with other observers that perforation is the exception rather than the rule in recurrent inflammation. In the chapter on the sequelæ of inflammation of the appendix there is reference to peritonitis, to fistula, to pyelephlebitis, to suppurative hepatitis, and to perinephritic and subdiaphragmatic abscesses. The author does not attach much importance to McBurney's point as a diagnostic resource.

With Treves he protests against the tendency to resort to laparotomy in all cases.

The book gives a very complete *résumé* of the literature of the subject, and it will prove interesting to all desiring an acquaintance with our knowledge of it up to the present day.

A Chapter on Cholera for Lay Readers: History, Symptoms, Prevention, and Treatment of the Disease. By WALTER VOGHT, Ph. B., M. D., Medical Director and Physician in Charge of the Fire Island Quarantine Station, Port of New York; Fellow of the New York Academy of Medicine, etc. Illustrated with Colored Plates and Wood Engravings. Philadelphia: The F. A. Davis Co., 1893. Pp. viii-107. [Price, 75 cents.]

In this little work the author succinctly tells what cholera is, briefly reviews its history both in Europe and in the United States, gives the symptoms that may enable the diagnosis of the disease to be made, makes such suggestions regarding the treatment as will enable a layman to assist himself in the absence of a physician, discusses the prevention of the disease, describes the method of handling an outbreak on shipboard or at a quarantine station, and recommends various methods of disinfection for different articles.

The work is clearly written, with evident care to avoid as much as possible the use of technical terms, and we believe it will prove to be quite serviceable for the purposes for which it is intended.

There is a slight misstatement on page 33, that the cholera spirilla retain their vitality in sea water for four days; Kin-

you's experiments showed that they would remain alive in it for more than two months.

A Manual of Diseases of the Ear. By GEORGE P. FIELD, M. R. C. S., Aural Surgeon to St. Mary's Hospital, etc. Fourth Edition. Illustrated with Colored Plates and Woodcuts. Philadelphia: Lea Brothers & Co., 1893. Pp. x-382. [Price, \$3.75.]

This new edition of Mr. Field's excellent work contains the essentially important advances made in otology during the ten years that have passed since the appearance of the third edition. In the chapter on tinnitus aurium an important section on the use of the galvanic current has been added. The illustrations that have contributed very largely to the value of the former editions are supplemented by some beautiful drawings. The volume is one of the best guides, for the practitioner or the student, with which we are acquainted.

Handbook of Physiology. By W. MORRANT BAKER, F. R. C. S., Lecturer on Physiology at St. Bartholomew's Hospital, and VINCENT DORMER HARRIS, M. D. Lond., F. R. C. P., Demonstrator of Physiology at St. Bartholomew's Hospital, etc. Thirteenth Edition. With upward of Five Hundred Illustrations, including some Colored Plates. Philadelphia: P. Blakiston, Son, & Co., 1892. Pp. xvi-884.

This is the well-known Kirkes's *Handbook of Physiology*. The fact that this is the thirteenth edition speaks of itself for its continued popularity. It has been brought up to date in every respect, and stands easily first among the minor compends of this subject.

Anatomy. A Manual for Students and Practitioners. By FRED. J. BROCKWAY, M. D., Assistant Demonstrator of Anatomy, College of Physicians and Surgeons, New York, and A. O'MALLEY, M. D., Instructor in Surgery, New York Polyclinic. Philadelphia: Lea Brothers & Co., 1892. [Students' Quiz Series.]

The volume before us is one of the series issued under the able editorship of Dr. B. B. Gallaudet. It is mainly founded upon the works of Henle, Quain, and Gray, and is in every respect a worthy and useful book to have at hand in library, office, or dissecting room.

The Chemical Basis of the Animal Body. An Appendix to Foster's Text-book of Physiology (Sixth Edition). By SHERIDAN LEA, M. A., D. Sc., F. R. S., University Lecturer in Physiology in the University of Cambridge, etc. New York: Macmillan & Co., 1893. Pp. 288. [Price, \$1.75.]

As the title indicates, this is a part of Foster's *Physiology*, and is a volume wholly devoted to the chemistry of the animal organism. In it are treated of in great detail the proteids, the carbohydrates, fatty acids and fats, amides and amido acids, urea and uric acid, the xanthin group, the aromatic series, the ptomaines, the bile-acids, and coloring matters of the animal body, of blood, bile, urine, retina, and corpus luteum. It might well be studied by the advanced student after grounding himself in Pellew's work recently noticed by us.

BOOKS, ETC., RECEIVED.

The Law of Cremation. An Outline of the Law relating to Cremation, Ancient and Modern, together with the Rules and Regulations of Various Cremation Societies at Home and Abroad. By Aubrey Richardson, Solicitor. London: Reeves & Turner, 1893. Pp. iv-187.

On Chorea or St. Vitus's Dance in Children. By Octavius Sturges, M. D., F. R. C. P., Senior Physician to the Hospital for Sick Children, and to the Westminster Hospital. Second Edition, revised, and partly rewritten. London: John Bale & Sons, 1893. Pp. xi-188.

The Bacterial Poisons. By Dr. N. Gamaleia. Translated by E. P. Hurd, M. D., Newburyport, Mass. Detroit: George S. Davis, 1893. Pp. xiii-136. [The *Physician's Leisure Library*.]

Sterility in the Woman and its Treatment. By Dr. De Sinety. Translated by E. P. Hurd, M. D. Detroit: George S. Davis, 1893. Pp. 130. [The *Physician's Leisure Library*.]

Weekly Abstract of Sanitary Reports issued by the Supervising Surgeon General M. H. S. under the National Quarantine Act of April 29, 1878. Vol. VII. (Nos. 1-53.)

The Indications for Amputation in Chronic Diseases of the Larger Bones and Joints with a Report of Seventeen Recent Cases, including Three Successful Amputations at the Hip Joint. By J. E. Summers, Jr., M. D., Omaha, Neb. [Reprinted from the *Omaha Clinic*.]

Myxœdema, its Histology, Ætiology, Pathology, and Treatment. With Particulars of a Case successfully treated. By J. Lindsay Porteous, M. D., F. R. C. S. Ed. [Reprinted from the *American Therapist*.]

Miscellany.

The Modifying Influence of one Disease upon Another.—In the address in medicine delivered at the meeting of the British Medical Association by Dr. David Drummond, for advance proof-sheets of which we are indebted to the *British Medical Journal*, we find the following:

"Passing on from the part of my subject that purports to give prominence to the causal relations of morbid entities, I come to consider briefly some possibilities in the modifying or controlling influence exercised by one disease upon another, and even in this enlarged sphere of inquiry we walk by the light of this principle of causation.

"I may commence with this proposition, that familiar clinical pictures of disease of an organ are often the product of the symptoms peculiar to it, and of others which are the expression of impaired function of another organ. In other words, the full symptom-complex of disease of one organ may be largely contributed to by disease of another, whether produced by the same or some other cause. I can best illustrate my meaning by an example. A patient addicted to alcoholic excess for a considerable number of years is known to be suffering from a group of dyspeptic symptoms, ascribed by the patient, friends, and doctor to this cause, but without a suspicion of gross organic mischief underlying them. This state of health interfered but slightly with the discharge of public and private duties, and indeed, beyond loss of flesh and some discomfort, there was a complete absence of signs of disease. An attack of pneumonia, which tried his powers of endurance considerably and was followed by a slow convalescence, completely altered the character of the case. Within a fortnight or three weeks of the incidence of the pulmonary disorder the abdomen swelled and its superficial veins enlarged, the lips became red and the tongue glazed and red, the face pinched and the urine scanty and full of urates, the motions black, and in every way a most suggestive picture of cirrhosis of the liver was presented, a transformation that astonished the doctor and friends, and was not at first sight easily explained. The only reasonable assumption to account for the apparently rapid development of cirrhosis of the liver was that the disease had existed for a considerable period in a latent form, and that the obstructed portal circulation was compensated for by the usual auxiliary relief, which served to reduce congestion, and thus keep in check the tendency to ascites, etc., until the attack of pneumonia, by producing cardiac insufficiency, upset the balance and led to the appearance of the typical signs hitherto absent. Let us observe that though the pathological changes characteristic of cirrhosis were present, the clinical aspect of the case was incomplete until a new and necessary factor, which had nothing to do with the original disorder, revealed the true nature of the illness. It seems a just inference that the cardiac affection made an important, if not essential, contribution to the completion of the symptom-picture. Indeed, I am disposed to think that in cirrhosis of the liver generally the occurrence of the abdominal dropsy largely depends upon the super-venition of heart weakness. In further support of this view I may mention a very striking case recently admitted to hospital under the care of my colleague, Dr. Limont. The patient, a waiter, a confirmed toper, though active and in fair health, and capable of performing his daily work in a large hotel, developed very suddenly the symptoms of portal obstruction—ascites, etc.—as the result of a few days of exceptionally heavy spirit drinking. His abdominal distention, becoming very great, was relieved by tapping, but an attack of peritonitis rapidly brought the case to a fatal termination. A post-mortem examination revealed a small hob-nailed liver, extensive splenic adhesions, an ample

auxiliary portal relief, and a heart greatly dilated. Here, again, we would have had an incomplete clinical case, but for a symptom which the liver borrowed from the heart. In this connection I may remind my audience that it is not unusual for the dropsey of chronic Bright's disease to be determined by heart weakness. Another illustration of the truth of Agrippa's fable, as told by Livy, in which he insists on the intimate connection between the various parts of the human body.

"But it is not enough to say that clinical pictures may be the joint products of symptomatic morbid relations, for they are often presented to us under the modifying influence of a tendency or bias lent by a former or a concurrent disease; that is to say, it is quite common to meet with pronounced modifications in the clinical pictures of disease which can only be accounted for on the principle that one disease has a determining influence upon the aspect of another. The following illustration will explain my meaning. A young man, aged twenty-two, suffered in the autumn of 1891 from an attack of alcoholic paralysis which revealed itself in the usual form of weakness in the legs, flapping of feet in walking, with, eventually, ankle-drop and paralysis, and paresis of the extensors of the fingers, along with which were severe myalgic pains. He recovered satisfactorily, and at the end of four months he was able to walk, and a little later to ride his bicycle. In May of the following year he had an attack of diphtheria, and in a few weeks, while strictly temperate, he developed, without any defect of sight or impairment of swallowing, numbness and weakness of the legs and hands, and indeed a very similar condition to that which had existed previously, except that the pains were absent. In this case the diphtheritic palsy was exhibited in a somewhat unusual form, in consequence of a predisposition to a special paralytic distribution lent by an attack of alcoholic neuritis. I am aware that cases of diphtheritic paralysis are met with where the lower extremities bear the brunt of the poison, but it is exceptional to meet with so pronounced a paraplegia in the entire absence of the usual signs, such as failure of accommodation, dysphagia, etc.

"Or take this case. A man in the prime of life, who was much addicted to alcohol, came under observation for complete double drop-wrist, presenting every feature of a plumbic case. His history revealed the fact that twelve years previously he had suffered from lead palsy, with blue line, the result of drinking contaminated water, and as he was recovering he acquired intemperate habits and developed into a chronic toper. The consequence was that the paralysis of the extensors became more pronounced, and remained permanent. There was absolutely no paralysis of the lower extremities, and the knee-jerk was normal.

"The modifying influence of one lesion upon another may be, as is well known, decidedly beneficial. Thus, sarcoma and lupus may yield to the poison of erysipelas; of which fact, it is reasonable to suppose, more will be made in the immediate future.

"The controlling effect of disease on disease is also to be seen in the fact that it is quite rare for pulmonary tuberculosis to spring up in the course of a cardiac affection. And, again, it is not unusual when lardaceous disease develops in consequence of chronic phthisis, to observe a distinct tendency on the part of the tubercle to be arrested in its growth. And, further, in this connection I may mention that I have been struck with the rareness with which a pneumonia complicated with jaundice proves fatal.

"I make a brief allusion to these points in order to realize the main aim of this address—namely, the arousing and quickening of an interest in the study of morbid relations, wherein our success will much depend on our having a ruling principle for our guide, and a definite object and end in view, both of which I have endeavored to indicate. An inquiry into the symptoms, diagnosis, prognosis, and treatment of disease can not fail to be greatly facilitated by keeping ever before us the particular cause or causes at work in producing an uncomplicated disease, or in furnishing the kaleidoscope aspects of many of our cases. In one way it seems a work of supererogation to inculcate the close observance of causes; for, as a rule, the practitioner gradually comes to perceive its importance, and shapes for himself an unwritten compendium along this line. His 'experience is by industry achieved, and perfected by the swift course of time.' Automatically he seeks for the cause, and is—or should be—satisfied only when he has found it; and that he

may register his observations he is driven to an accurate system of nomenclature, which shall possess for him both an aetiological and a diagnostic value. Every advance in this direction is a positive gain to medicine; and whether we succeed in tracing a disease to its true origin, or attempt the more arduous task of disentangling the morbid web with a view of assigning its due proportion of responsibility to each factor, and so of dealing with the whole, we are engaged in the employment of a method which, if developed, may make a revolution both in the name and treatment of diseases. This is no mere fanciful theory, for it will be found that every scientific medical man unconsciously and even automatically, as I have said, finds himself perpetually engaged in practicing it, and the measure of success he enjoys as a practitioner of the healing art is determined largely by the degree to which he permits himself to be led by its light. A man may never be fortunate enough to make an abiding contribution to the science of medicine strictly so called, and yet may all through his life have given the public the practical benefit of his originality and independent thought in the adoption and practice of self-taught rules without the aid, or even in spite of the trammels, of hampering traditions. And there are many such among us who whisper their worth in the ear of the public, but seldom seek to proclaim it from the literary house-top. To him belongs the credit of benefiting mankind by the practice of unformulated methods, and he shall have his reward: *Denn Gott lohnt Gutes hier gethan, auch hier noch.*"

The Examination of Cholera Discharges.—With the same appreciation of the value of early and positive diagnoses that has been shown by our city board of health in the matter of diphtheria, the *British Medical Journal* for July 29th says editorially:

"With cholera at our gates, it behoves us to be prepared to recognize the disease in its very earliest stages. So far as our knowledge goes at present, there is no method that is at once so rapid and so reliable as the determination of the presence of Koch's comma vibrio in the alvine discharges of the patient. In a short note on a communication published by Koch in the *Zeitschrift f. Hygiene*, we indicated briefly the methods on which a skilled bacteriologist relies for his diagnosis, but now that a case has already appeared in this country, and as a medical officer of health may be called upon at any moment for a definite opinion, a further and more detailed account of the modern method by which the specific nature of choleraic discharges can be determined is certainly not out of place in our columns. These methods of diagnosis are (a) by the microscope, (b) by cultures, and (c) by chemical tests, or by combinations of two or more of these methods.

"(a) By the microscope: A drop of the contents of the intestine in the preferably fresh condition is mixed with a drop of tap water and spread out on a microscope slide, with a platinum needle or a glass rod, a cover glass is placed in position, and the specimen may be examined at once. In the words of the note to which reference has already been made: 'In about half the cases examined, a rapid microscopic examination of the materials forwarded to him from various parts of Germany enabled him to telegraph almost immediately that the patient from whom the dejecta had come was affected with cholera. In the mucous threads and flakes examined under the microscope the cholera bacilli are arranged in groups, in which the single bacilli run parallel to one another like a shoal of small fish following one another in a stream of water. This appearance Koch regards as so characteristic that where it is present he does not hesitate to form a diagnosis.'

"To prepare a stained specimen, a trace of the intestinal discharge is in the same manner mixed with a drop of water and is then allowed to dry at the temperature of the room. The cover-glass may then be passed two or three times rapidly over a spirit lamp or gas flame, after which it should be stained for a minute or two with a watery solution of fuchsine or Spiller's purple, and then carefully washed with clean water. It may be examined at once. The cholera vibrio in such preparations is usually seen in the form of slightly curved (sometimes straight) rods, with an average length of 1.5μ ($= \frac{1}{10000}$ of an inch, or half the diameter of a red blood-corpuscle), and a breadth of about 0.4μ . The ends of the rod are usually somewhat rounded. From its curved shape the organism has been described as a comma bacillus. These curved bacilli appear to be formed by the segmentation of a

spirillum, and the segments may consist of a single comma-shaped organism or of two curved in the same direction so as to form a more or less complete circle, or with the curve reversed so as to form an S-shaped organism. When stained with Spiller's purple the organism appears to be somewhat plumper than when stained in fuchsine. As soon as the material comes to hand a particle should be thoroughly mixed in a test tube with a solution of one per cent. peptone in a one-per-cent. solution of common kitchen salt. This may be sterilized by boiling for an hour in an ordinary saucepan, but if it is to be used at once, this is not necessary; the mixture is simply filtered before the suspected cholera material is added. A drop of the inoculated mixture is then placed on a square cover-glass, which is inverted and supported at its four corners by small fragments of sealing wax, which are fixed to a microscope slide. Slips of moist blotting paper are laid around the cover in order that the air in the chamber may be kept charged with moisture, so that evaporation from the hanging drop is prevented as much as possible. This preparation is now placed in a warm damp place. At the end of five or six hours the preparation may be examined, and if there are any cholera vibrios present they multiply so much more rapidly in the above solution that characteristic spiral threads, single bacilli, etc., may be seen in enormous numbers, especially near the surface of the drop—that is, away from the cover-glass, before other organisms have time to develop to any marked extent. Instead of the peptone-salt solution, dilute bouillon may be used for these hanging-drop cultures, but in this case the process goes on somewhat more slowly, and threads are more frequently formed.

"(b) By cultures: The above hanging-drop culture should properly come under this heading. If time were a matter of no importance the gelatin-plate method would in most cases give sufficiently accurate results in twenty-four hours. Plate cultures are made in the ordinary fashion, and then at the time mentioned there appear small white points, many of which are at first deep down in the gelatin; after a time these bring about liquefaction of the surrounding gelatin, especially those in contact with the air, which exhibit a peculiar funnel-shaped depression with a clear, glossy-looking margin, and in the center (when seen under the microscope $\times 100$) is a somewhat coarsely granular gray or grayish-yellow mass; and as the liquefaction goes on there appears a peculiar pinkish tinge at the margin of the irregular granular colony. The surface of these colonies is sometimes said to resemble a layer of minute fragments of broken glass. At the same time that these plate cultures are made a flask containing dilute sterilized bouillon, one part bouillon to two or three parts of water, or the peptone-salt solution above mentioned, should be inoculated with a small quantity of the cholera material. This may be at once placed in an incubator at a temperature of 38° to 39° C. At the end of eleven or twelve hours in the case of the broth culture, or of seven to eight hours in the peptone culture, the cholera organisms greatly outnumber most of the other putrefactive organisms, especially near the surface of the culture medium, where a somewhat wrinkled film, consisting almost entirely of cholera organisms, is formed. A little of this film may be inoculated into another flask containing broth or peptone, or plate cultures may be made. Microscopic preparations should also be made and examined. The cholera organism, which appears to have a very great affinity for oxygen, comes to the surface, there grows rapidly, and gets so great a start of the other organisms that at this stage we may have it in an almost pure culture.

"At the same time that the inoculation is made into the peptone, the following method, which in the hands of Freymuth and Lickfeld has given rapid and very reliable results, may be used; they are able, by their method, to diagnose the presence of cholera bacilli within six hours. On a number of microscopic slides they spread a thin layer, while still warm, of the following nutrient medium: 900 c. c. of broth, 12 c. c. of glycerin, 12 c. c. of gelatin, and 30 c. c. of agar, which, on cooling, solidifies; over the solidified surface they paint with a camel's-hair brush this same warm fluid nutrient medium, to which a few drops of the cholera material have been added; the slides are then placed in Petri's dishes (flat glass dishes with covers) and are kept at a temperature of 38° or 39° C. for several hours. These slides can be examined under the microscope from time to time with comparatively high powers.

"At the end of five hours and a half with the Zeiss AA or even D objective, and ocular No. 2 or 4, there are seen well-marked colonies of various sizes and colors. (To the naked eye we have an appearance somewhat like a layer of dust on the nutrient medium.) Their apparent diameter varies between a half and two millimetres, while they vary in color from a clear steel-blue to a dull brown. Most of them have the appearance of a distinct mosaic, in which are dark streaks and points; a few of the blue colonies are, however, almost homogeneous, while others appear as though they had been dusted with dust. The outline is usually slightly irregular, and somewhat finely indented. Under the microscope the organisms of which these colonies are composed have all the characteristic appearance of the cholera bacillus, as found in the intestinal contents. The great advantage of this method is that a diagnosis may be arrived at in a comparatively short space of time, and is certainly an addition to the bouillon, salt solution, and ordinary plate-culture methods.

"From the colonies, either on gelatin or on the agar slides, gelatin-tube cultures may be made which have the following characteristic appearances: There very quickly grows along the path of the inoculation needle a somewhat regular growth rather more marked near the surface. At the end of twenty-four hours liquefaction goes on in a funnel-shaped area near the surface, and a little clear air bubble (a very characteristic appearance) is seen; later the growth settles to the bottom of the funnel, and ultimately, on the third or fourth day, the funnel-shaped area has become very well marked, and contains a clear fluid gelatin, at the bottom of which is collected a white or grayish-white mass, while along the track of the needle, where a little tube of liquefied gelatin has formed, the growth, as the funnel becomes deeper, gradually settles down into a kind of a coil or spiral, like a coil of white string lying in clear water.

"The true cholera bacillus may be distinguished from Deneke's cheese spirillum and the Finkler and Prior spirillum, both of which have been said to resemble this organism, by the fact that in the case of these latter organisms the liquefaction takes place much more rapidly, and the liquefied gelatin, in place of being clear, becomes more or less turbid, and in the case of the Finkler and Prior spirillum the peculiar ring is seldom present in the liquefied area.

"Agar tube cultivations may be made either directly from the faeces, or, better still, from the films that are formed on bouillon, etc. A small portion of the wrinkled film is taken at the end of eight or twelve hours, as the case may be, or from the colonies developed on the slides, on a platinum needle flattened to form a kind of small spatula. This, once charged, is drawn several times over the surface of an oblique agar mass in a test tube, and then in a similar way, without being freshly charged, over the agar in a second tube; in this way we have formed eight or ten streaks, each succeeding one containing fewer and fewer of the seed organisms, so that when we come to the fifth or sixth streak only discrete colonies, from which cultures may be made or which may be examined under the microscope, are developed.

"The flask cultivations in bouillon or peptone as recommended by Dunham are excellent for giving the cholera-red reaction—the one chemical reaction which is generally relied upon to determine the presence of the cholera organisms at an early stage. For this purpose the peptone solution appears to be superior to any other. At the end of about eight hours, if a small quantity of pure sulphuric acid be carefully added to a portion of the culture, there is developed, when the two fluids meet, a reddish violet color, which is spoken of as the cholera-red or indol reaction. This is not an absolutely specific test, but, along with the microscopic examination and the culture tests, it is of very great value, as by it we are enabled to determine the presence of the cholera organism, even when intestinal organisms are present, none of the spirilla in the intestine giving the same reaction, the only one that is known to do this being the *Vibrio Metschnikovi*, which has not yet been found under such circumstances. The bouillon must be allowed to incubate for twelve hours, when the same reaction may be obtained. It may also be obtained with a gelatin culture in which there is a quantity of peptone.

"Although most medical men in practice, with time, a little ingenuity, and a small amount of apparatus, might determine for themselves

in a very short time whether or no they are dealing with cases of cholera in which Koch's 'comma' bacillus is present, many will find it impossible to obtain sufficient leisure in which (especially at the time that the work must be done) to perform the experiments, while others again will be anxious to have their own results corroborated by men who are actively engaged in bacteriological investigations."

"Those who wish to send specimens for examination should in the first place send the material as fresh as possible in a well-stoppered bottle, the outside of which should be carefully washed with carbolic acid after the stopper has been put in position, and then dried, and the stopper luted in with paraffin, tied with string or wire, carefully sealed, and securely packed in a stout wooden box. As soon as it has been determined to send off a specimen, a telegram should at once be sent to the laboratory to which the specimen is being dispatched, in order that preparations may be made for the immediate examination of the material."

To Contributors and Correspondents.—The attention of all who purpose favoring us with communications is respectfully called to the following:

Authors of articles intended for publication under the head of "original contributions" are respectfully informed that, in accepting such articles, we always do so with the understanding that the following conditions are to be observed: (1) when a manuscript is sent to this journal, a similar manuscript or any abstract thereof must not be or have been sent to any other periodical, unless we are specially notified of the fact at the time the article is sent to us; (2) accepted articles are subject to the customary rules of editorial revision, and will be published as promptly as our other engagements will admit of—we can not engage to publish an article in any specified issue; (3) any conditions which an author wishes complied with must be distinctly stated in a communication accompanying the manuscript, and no new conditions can be considered after the manuscript has been put into the type-setters' hands. We are often constrained to decline articles which, although they may be creditable to their authors, are not suitable for publication in this journal, either because they are too long, or are loaded with tabular matter or prolix histories of cases, or deal with subjects of little interest to the medical profession at large. We can not enter into any correspondence concerning our reasons for declining an article.

All letters, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication. No attention will be paid to anonymous communications. Hereafter, correspondents asking for information that we are capable of giving, and that can properly be given in this journal, will be answered by number, a private communication being previously sent to each correspondent informing him under what number the answer to his note is to be looked for. All communications not intended for publication under the author's name are treated as strictly confidential. We can not give advice to laymen as to particular cases or recommend individual practitioners.

Secretaries of medical societies will confer a favor by keeping us informed of the dates of their societies' regular meetings. Brief notifications of matters that are expected to come up at particular meetings will be inserted when they are received in time.

Newspapers and other publications containing matter which the person sending them desires to bring to our notice should be marked. Members of the profession who send us information of matters of interest to our readers will be considered as doing them and us a favor, and, if the space at our command admits of it, we shall take pleasure in inserting the substance of such communications.

All communications intended for the editor should be addressed to him in care of the publishers.

All communications relating to the business of the journal should be addressed to the publishers.

Contributors who wish to order REPRINTS of their articles should do so on a blank prepared for that purpose, which will be sent to them by the publishers on receipt of a request to that effect. The order should be sent to the publishers, and not to the editor.

Original Communications.

THE SPHYGMOGRAPH

AS AN INSTRUMENT OF PRECISION.

By J. S. LEONHARDT, M.D.,
LINCOLN, NEB.

THE pulse has long been regarded as affording much valuable information in the diagnosis and prognosis of diseases. Chinese physicians are known to depend almost entirely upon it, professing to distinguish by the sense of touch alone several thousand distinct varieties. It has not been so very long ago that Caucasian professors discoursed learnedly on forty or fifty different kinds of pulses, embracing as many changes in speed, strength, volume, etc., all of which were much plainer on the printed page than when enunciated from the rostrum or searched for clinically. To Vierordt is generally conceded the honor of having rescued from a maze of confusion this important department of practical medicine. In 1855 he constructed a sphygmograph in which the movements of an artery were communicated to a lever which graphically recorded them. He was preceded, however, in a measure by Stephen Hales, an English clergyman, who in 1733 constructed an instrument for hydraulic and hydrostatic experiments on the circulation. He called his apparatus a "pulsanometer." Galileo, the founder of experimental science, is said to have made a "pulsilogia," but no description of this invention is extant. It remained for M. Marey, the master of the graphic method in physiological research, to invent a sphygmograph in 1860 that ushered in a new era in medicine. Numerous modifications of the original instrument have since been made, but, so far as I know, they all belong to one of two classes: (1) Those in which the marker moves at right angles to the movement of the receiving surface, such as instruments of the Dudgeon, Pond, and Landois pattern, and (2) those in which the recording needle always describes the arc of a circle whose radius is equal to the length of the lever moving around a center and in a plane parallel to the direction of the recording slide, as in instruments of the Marey, Holden, and Key type, as well as some of the tambour machines. These instruments have all done their part in extending our knowledge of the circulation, whether in a state of health or disease or during the use of measures or medicines for therapeutical or experimental purposes. The modern and perfected sphygmograph has as effectually displaced the *tactus eruditus* of the past as the stethoscope has the naked ear, the thermometer the open hand, or the microscope, ophthalmoscope, and laryngoscope the unaided eye. It is to these instruments of precision that modern medicine as a science owes so much of its imperial greatness, all of its magnificent possibilities; it is wholly due to them that its stately progress has been a veritable triumphal procession for half a hundred years at least.

The object of sphygmography is to measure the amount and duration of expansion of a pulsating artery, with the rapidity and intervals of these pulsations, to indicate the

behavior of the arterial current, as well as the vessel confining it, and to describe these things in its own cryptoglyphs on a receiving surface which may be preserved for reference and comparison. In order to accomplish all this in a practical and satisfactory manner it is essential that the instrument be compact in structure, easy of application, capable of ready adjustment for pressure, so that the best definition of pulse curves may be easily and quickly obtained, and constant in operation, and that it produce a tracing of known magnification and on a surface propelled at a known and uniform rate of speed.

A finished tracing is called a sphygmogram and consists of a series of curves representing pulse waves, any one of which from a given point on any curve to a corresponding point on the succeeding curve represents one complete cardiac cycle. The tracing of any single pulsation in a normal sphygmogram consists of the following events, beginning at the lowest point in the tracing and reading it from left to right: An almost vertical line starting from a level known as the basal or respiratory line. The left ventricle having discharged its contents into the arteries, a blood wave is produced, which, suddenly distending the partially filled vessel, throws the marker or needle upward. The inertia of the lever causes the needle to be carried farther than the distention of the artery would have carried it, and after having reached the highest point it rapidly descends until caught by the flow of the arterial tide corresponding in time with the formation of the first notch. This is the first event, the commencement of which is synchronous with the opening of the semilunar valves of the aorta and the end with the closure of the auriculo-ventricular valves.

It is termed the percussion or systolic stroke or wave, upstroke, primary ventricular wave, etc. The acute angle formed by the upstroke and its sudden descent as far as the first notch is the apex or summit of the percussion or systolic wave or stroke. The next event is a second wave, known as the predicrotic or first tidal wave. It is caused by the closure of the aortic valves, which agrees in time with the formation of the second notch, which therefore marks the end of the systole. The next important event is another wave, the dicrotic or aortic (*Rückstosswelle* of Landois), and is due to the recoil of the column of blood against the closed aortic valves. Sometimes a fourth wave may be seen; it is also due to a recoil and has no special significance so far as is known at present. This, briefly, is the generally accepted translation of a normal sphygmogram, the several events of which can be readily seen in the figure, which represents a tracing taken of the writer by himself with a Dudgeon sphygmograph, under a pressure of five troy ounces, over the left radial artery, beating sixty-eight times a minute. Any sphygmograph in proper working order will show these several characteristics in a healthy

pulse. Curves drawn upon a surface moving at different rates of speed, while apparently quite unlike, nevertheless record exactly the same facts. The distance between pulse curves depends, of course, upon the rate of the pulse and the speed of the recording surface; it is shorter when the pulse is rapid or the motion of the cardboard slow, and greater when the pulse is slow or the motion of the paper fast. Take, for example, a pulse beating sixty times in a minute: traced with an instrument moving the recording surface at the rate of an inch in a second, it will show one curve to the inch; if the pulse beats a hundred and twenty times in a minute, and the motion of the cardboard is not increased, it will show two to the inch; let the cardboard be moved two inches in a second, and a pulse of sixty to the minute will show one pulse curve to every two inches, etc. Therefore if the pulse rate by the minute or the movement of the recording surface by the second is known, either will furnish a good and sufficient basis of comparison between different sphygmograms regardless of the make of instrument with which they were drawn, the only requirement being that the instrument be true to itself, that the operator be competent to manipulate the thing, and that in drawing his ordinates, for the purpose of measuring events, he bear in mind that they must always be parallel to the signal line, whether that is the arc of a circle, as it is when made by instruments of the Marey style, or a straight line, as it is when made by instruments of the Dudgeon class.

The reader will understand from the foregoing why it becomes almost necessary to notice a few remarks made by Dr. Hammond in a recent article in reply to my criticism of his contribution under the title *Cardine*, which appeared in a recent issue of the *New York Medical Journal*. Sphygmography needs no defense at my hands, but Dr. Hammond has given expression to some remarkable statements and ideas, which for his sake I wish he had never committed to print rather than for fear of any damage they may do the graphic method of research. True, I do not carry the ghosts of three or four professorship scalps at my belt, neither am I, or ever have been, a member of some fifteen different societies, domestic and foreign. If Dr. Hammond "can not boast of having several thousand sphygmograms," neither can I of having used "Marey's and Pond's sphygmograms, the one for over thirty years and the latter for more than twenty years." I have seen Marey's instrument in all its Parisian glory; it is a cumbrous affair, difficult of adjustment and impracticable for office work, and at its very best makes only "a tolerably good tracing." It was introduced before the Medical Society of London in 1865 by Dr. Anstie. Dr. Hammond is to be congratulated upon having introduced it into the United States several years before Dr. Anstie did as much for England. It is a little strange, however, that Dr. Hammond should have been able to use Pond's instrument three or four years before it was invented. It is still more strange that Dr. Hammond should have used any sphygmograph "for over thirty years" and still believe that a less vertical upstroke shows increased force, when exactly the reverse is true. It is most strange that he could use a sphygmograph all this long time and yet believe that the distance between any two

upstrokes is shorter when the recording surface moves rapidly and longer when it moves slowly, the reverse being true. This must certainly be a "matter of opinion," for it can not be a matter of *fact*. I trust he did not form this "opinion" from reading the French classic *Physiologie médicale de la circulation du sang*, Paris, 1863. I suppose Dr. Hammond will again accuse me of having violated the decorum of controversy and committing "a solecism against good manners"; if so, I beg him not to trouble himself with seeking an excuse for my breach of etiquette this time.

In regard to the sphygmograms illustrated in the issue of this journal for April 22, 1893, which, it is alleged, show the favorable effect of "cardine" as a heart tonic, I desire to reiterate what was said in my criticism of the article—that they are not normal sphygmograms, and that they are unworthy of the least confidence as indicating anything favorable in the circulation—and I challenge their defender to prove them healthy tracings by any rule of sphygmography or process of reasoning whatever. For him to say "I say they do" is no answer. At first I did not believe the cuts were exact reproductions of actual sphygmograms, but he says "they are," and that settles it. One may be an amateur sphygmographist and not find it an impossibility to send tracings long distances "without the great risk of having them obliterated or seriously damaged before they reach the engraver." While I do not profess to know all that is to be known on the subject of sphygmography, I am in possession of a few facts "that every schoolboy ought to know," and they became mine before Nature crowned me with "the silver'd livery of advised old age."

A CASE OF SYMPHYSIOTOMY.

By J. O. COBB, M.D.,

PASSED ASSISTANT SURGEON, U. S. MARINE HOSPITAL SERVICE,
PORT TOWNSEND, WASHINGTON.

Mrs. S., primipara, patient of Dr. House, was in labor for two days, when I was called in consultation. Forceps delivery had been tried three times, but without any success. It was impossible to turn.

On examination, it was found that the head was not engaged at the superior strait. The pelvis was found to be slightly deformed, the transverse diameter being diminished while the antero-posterior was lengthened.

The child's scalp was contused and swollen, but it was thought that by severe lateral pressure with the blades of the forceps the head might be compressed enough to deliver. Neither Hodge's nor Elliott's forceps would hold with the powerful traction that was exerted. As the child's head had just ceased to beat, symphysiotomy was advised and performed.

The operation was performed by making an incision two inches long over the symphysis, through the skin and fat. Then the muscular tissue was pushed aside with the finger and a probe-pointed bistoury passed behind the ligaments and the cut made downward and forward, until the ligaments were felt to give way. The incision in the skin extended from a quarter of an inch from the edge of the commissure upward for two inches. This was done to keep a mucous surface out of the incision.

As soon as the ligaments were severed the forceps was ap-

plied and the child quickly extracted. It was dead; and as the mother needed prompt attention, no effort was made to resuscitate the child.

In the extraction of the child the pelvic bones separated fully three inches and a half. The separation was so great that the vagina was torn and a communication was thus made from the vagina into the incision. No attempt was made to stitch the ligaments together. Deep silk sutures were passed through the skin and muscular tissue.

The perineum had been ruptured through into the rectum, due to the slipping of the forceps. No attempt to repair this damage was made at this time. This was subsequently repaired by Dr. House. At the present time, two months after the operation, the patient can walk about her room, there being no motion between the bones.

The patient had no untoward events except a stitch abscess and a slight rise of temperature for a week.

THE CONVALESCENCE FROM FRACTURES.

By GEORGE W. KING, M.D.,

HELENA, MONTANA.
SURGEON TO THE MONTANA MINING CO., LIMITED.

AUTHORITIES lay but little stress upon this most important period in the treatment of fractures. The proper reduction and retention of the fragments of a broken bone is considered the principal thing to insist upon. The fear of shortening or angular deformity has no doubt been responsible for many imperfect recoveries. It has prompted too long continued immobilization with resulting loss of function that in many cases is never wholly regained.

We are told in detail how bones unite, how special fractures should be treated, the length of time required for union to take place, etc. If these were all the facts to be considered we might with propriety omit any further investigation of this subject. Unfortunately, such is not the case, and we must continue our efforts to perfect the methods at hand.

The many conditions and influences that may hasten union of bone, such as age, location of fracture, ability of reduction and retention, general condition, and previous habits of the patient, are well known and preclude the possibility of any definite rule for guidance as to the length of time immobilization should be employed. Each case must be left to the judgment of the attendant.

Many surgeons, doubtless the majority, are inclined to assume that their duties are ended upon the removal of the retention apparatus. This is certainly a dangerous practice and can not be recommended in any case. Numerous instances have occurred under my own observation where an excellent result has been compromised by want of care after removal of the splints and bandages.

The production of curves that Nature never intended is neither creditable to the surgeon nor useful to the patient.

We can only avoid such unpleasant complications by familiarizing ourselves with the different stages in the progress of recovery. No difference of opinion exists among surgeons as to the advisability of immobilization in all traumatic ruptures of bone. No exception is made in

cases where there is no displacement at the time of injury. Common prudence suggests this course as a preventive measure, for no one can tell what harm movements of the patient or muscular contraction may do.

Practically, then, we have to deal with the effects of immobilization during the convalescence in every case of fracture. The number of cases presenting themselves to the surgeon to obtain relief by operation months, even years, after the injury, is greater than physicians who do not undertake surgical cases are aware of—far greater, indeed, than it should be. Much better results are possible if we choose to adopt methods based upon a thorough knowledge of the processes involved in the healing of fractures.

The condition of a limb after being immobilized for several weeks is one of complete helplessness. The appearance is more or less characteristic, the whole limb shrunken, the muscles lax and without resistance, the skin smooth and glossy.

Muscular atrophy is nearly constant, though varying in degree; it is not limited to the injured part, but extends to the superior and inferior portions of the limb.

Recovery from this condition is very slow. Cases have been cited in which, some years after, there still existed a marked degree of difference in size between the healthy and injured limb. The pathology of muscular degeneration subsequent to fracture is not positively known. Whether compression and immobilization are alone responsible for it requires further proof.

A sufficient number of experiments upon healthy limbs ought to demonstrate how much is due to this cause. I am not aware of any particular evidence in this connection, aside from that furnished by cases of fractured femur, in which both limbs are included in the immobilization apparatus. It is stated upon good authority that the atrophy is greatest in the injured limb.

Increased nutrition incident upon the formation of the callus is thought by some to impair the general nutrition of the limb. Observation and experience fail to sustain this theory. Contusion of nerve filaments, inducing neuritis, has been named as a cause. Whatever may be the true pathology, it is evident that disuse of a limb is an important factor in producing loss of function. We know that muscles deprived of their normal stimuli are poorly nourished, and degeneration of their fibers takes place.

Other changes to be mentioned relate to the venous circulation in the injured part; to these are due some of the disagreeable symptoms occurring at this time, notably the oedema that usually persists for an indefinite time and becomes troublesome when the limb is pendent. To what is this abnormal condition of the circulation due?

Can we explain it by the vaso-motor theory, or consider it purely mechanical? At the seat of injury there must necessarily be extensive rupture of the veins, which would naturally affect the return current through the part. Probably many of the smaller veins are obliterated, in some instances by pressure, in others by thrombi that effectually obstruct the vessels. In consequence of this mechanical interference, swelling occurs and persists until collateral

circulation has become sufficiently established to empty the vessels. Perhaps the complication most to be dreaded in the secondary stage is that of stiffness of the joints in the vicinity of the fracture. Much of the disability in the early convalescence is due to this cause; the tendons no longer glide smoothly as in health, the limited amount of motion is painful in the extreme, and the joint, like a rusty hinge, is unfit for service until its freedom of motion is restored.

How shall we treat these conditions? It is not sufficient to simply tell the patient to use the limb, for, when he attempts to follow this advice, he is quickly made aware of its weakness. Every movement is painful, and he is for this reason more apt to desist from his efforts than to persevere, and is therefore too willing to trust to time to work a cure. We know such reasoning is fallacious, as we have seen; there must be a restoration of the circulation to nourish the part, the muscles must be stimulated to action, and the joints freed, before we can hope for any progress toward recovery. It is therefore a very unwise procedure to trust this important period to the patient himself. It is at this time we are able to do more toward restoring the normal functions than at any subsequent time. Experience teaches us that these cases are especially liable to become obstinate after several months have elapsed. There remains to consider what measures to adopt whereby we may avoid the many complications, or at least reduce them to a minimum. The indications are plain enough and have already been shown in referring to the effects of immobilization. From careful investigation, I am led to believe that massage promises the best results in the conditions named. By massage I do not mean the promiscuous rubbing usually indulged in. Neither the rough, clumsy manipulations that endanger the continuity of the partially formed callus, but the light, skillful touch of the "masseur" applied scientifically. Of course, it is unreasonable to suppose that physicians are ordinarily masters of this art, yet enough of the science ought to be acquired with but little trouble to carry out the treatment here advised. The advocates of the massage treatment of fractures without immobilization claim good results—equal if not superior to that obtained by the time-honored custom by splints, extensions, etc.

They bring to their aid in proof of the correctness of their views examples furnished by the history of fractures among animals, where immobilization is impossible and yet union takes place. Admitting this to be true, I imagine few of us would care to take the risk of treating fractures without employing some retaining device until the danger of displacement had passed.

When shall we begin the use of massage?

At the very earliest moment that it can be done without causing displacement. A judicious selection of a retention apparatus that will allow free access to the limb without removal of the entire dressing is an advantage, particularly at the beginning of treatment. My preference is for the plaster-of-Paris splint, for it can be readily opened and closed without deranging the fragments. By this plan we shall be able to not only combat successfully the degenerative changes in the muscles, but to keep the

circulation in its proper course, thereby aiding the rapid absorption of excessive effusion that so frequently delays the normal process of healing. The same treatment applied to the joints keeps them pliable and ready for use when the time comes to resume their functions. With the nutrition of the limb provided for, the articulations guarded against abnormal conditions, we shall have done our part toward insuring results of which we need not be ashamed.

729 FIFTH AVENUE.

A PREHISTORIC DENTAL ANOMALY.

BY A. L. BENEDICT, M.D.,
BUFFALO, N. Y.

I wish to record an instance of supernumerary tooth occurring in a skeleton—presumably that of an Indian—which was exhumed from a knoll near an old Indian cornfield on the east bank of Canandaigua Lake. Part of one or two other skeletons had previously been removed by the owner of the farm. No other remains were found; but the gravely subsoil had been disturbed in an area six or eight feet in diameter by the insertion of clay and sand to the depth of about four feet. Throughout this inserted soil, charcoal (mostly oak with one pine-knot) and calcined stones were found. At another spot in the same knoll there was uncovered a fireplace, circular and spherically convex, about three feet in diameter. A section through it showed four inches of charcoal and an equal thickness of baked clay. Immediately around and beneath this fireplace was shaley sand.

The skeleton lay on its left side, facing the west, the head pointing south. The arms were bent so as to bring the hands together near the face. The thighs were at right angles to the trunk, the legs flexed as closely as possible to the thighs. Judging from the development of the bones, the sutures, and the teeth, the skeleton was that of a medium-sized adult male in early middle life.

The supernumerary tooth was shaped like a stunted canine. The root, which was rounded off, projected slightly from the alveolar arch above the first right upper incisor. The crown lay in the anterior palatine canal, which was unusually large. This tooth was probably entirely hidden during life, though its possessor may have wondered what caused the little projecting knob under the gum. Certainly there was no caries or necrosis to indicate that a sinus led to either root or crown. The rest of the teeth were not remarkable, although some were decayed and a few missing. This case is in harmony with the observation that supernumerary teeth usually occur at the second dentition, in the upper jaw, and in connection with the incisors or canines.

The Nineteenth Annual Meeting of the Mississippi Valley Medical Association will be held in Indianapolis on Wednesday, Thursday, and Friday, October 4th, 5th, and 6th. A general session will be held each morning, and the afternoons will be devoted to section work. There will be three sections: One in General Medicine, one in General Surgery, and one in Obstetrics and Gynecology. The last mentioned has been added since the last meeting.

A CASE OF
COMPLETE GLOTTIC SPASM IN AN ADULT,
FOLLOWED BY
UNCONSCIOUSNESS AND PROLONGED DROWSINESS.*

By W. PEYRE PORCHER, M.D.,

LECTURER ON LARYNGOLOGY AND RHINOLOGY IN THE
CHARLESTON MEDICAL SCHOOL;
ONE OF THE VISITING LARYNGOLOGISTS TO THE CHARLESTON CITY HOSPITAL,
CHARLESTON, S. C., ETC.

As I have been able to find records of only twenty-seven cases of laryngeal vertigo or complete glottic spasm in adults, and on account of marked implication of the brain centers as shown by torpidity of bowels, persistent drowsiness, and other symptoms, which are novel, at least to the writer, I have ventured to make the following brief report of this case:

The patient was a maiden lady, aged fifty-two years, at the menopause. She was brought to my office for the supposed removal of large tonsils on account of difficult respiration at night, with frequent terrifying nightmares. She attributed this condition to an attack of grip which she had had several months before.

Since that time the paroxysm had not been severe, but her attendants stated that she would be awakened by the cough after dropping to sleep, and it was described by her as a feeling of choking or gagging in the throat. There was no dyscrasia, except such as resulted from a slight malarial cachexia. She was of a very sanguine temperament, inclined to plethora, and so nervous that she expressed the greatest alarm when requested to enter my dark room. She could not go into a church or other crowded place without a sense of fear and oppression.

On examination, her tonsils were found to be so small that they could not be caught in the grasp of either of two improved amygdalotomes. They were, therefore, thoroughly cauterized with the galvano-caustic knife.

She was ordered a simple antiseptic gargle of listerine and water, and cautioned against taking any hot food, coffee, etc.

The first night after the operation she had no great pain or unusual difficulty of breathing. The next morning she attempted to drink some coffee which she said was not hot. Upon taking the first teaspoonful she complained of a peculiar giddiness and rushed to the window for air, but fell back upon the floor unconscious. The attack lasted but a short time. On my arrival soon after, she had entirely regained consciousness and was comfortable. As her attendants stated that she was very drowsy, ten grains each of colomel and soda were ordered to be taken at once. At the evening visit it was found that the medicine had not acted, and the next morning there had been but one slight evacuation. This, together with the persistent drowsiness which lasted for several weeks, indicated that there was marked implication of the brain centers, although there had been no return of the attacks of insensibility.

She was ordered sulphate of strychnine, one twentieth of a grain, with one grain each of quinine and iron. This dose was gradually increased until one tenth of a grain of strychnine was taken three times daily. Small doses of a saline cathartic were also given from time to time in order to keep the bowels open.

About thirteen days after the first cauterization, the left tonsil remaining still somewhat enlarged, a second application of the galvanic electrode was made to it. This was followed by most satisfactory results. She informed me that her rest

the night following had been very refreshing, without difficult respiration, pain, or nightmares.

The patient was kept under observation for about fifteen days longer. At the end of this time she expressed herself as having regained control of her nerves, and considered herself well.

On account of the well-known tendency of hot coffee to enter the larynx, and for the reason that I know of no other cause to which to attribute the sudden attack of insensibility, as there was no paralysis present, I have been inclined to regard this as a case of laryngeal vertigo or complete glottic spasm, and have so entitled it. It might be thought that the vertigo was in some way due to the menopause, but this would not account either for the prolonged stupor or the torpidity of the bowels. Cases of laryngeal vertigo have been reported in which cough has either been absent or not of any great severity, and others in which the nervous element was most prominent, but in which there were no attacks of absolute insensibility, and again other cases in which very slight paroxysms of cough would be followed by complete unconsciousness. The insensibility with slight cough, as in this instance, is perhaps best explained by the theory of McBride that the attack was preceded by a series of short inspirations followed by spasmodic expiration and a partially closed glottis. Here, also, the patient was not even aware that any coffee had actually entered the larynx, but was seized with a sudden gasping for breath, and after rushing to the window fell unconscious, as she said, "in a heap upon the floor." It is the opinion of the writer that this loss of consciousness, like aural vertigo, is a symptom of a specific disease, and should not be confused with that vertigo which results from holding the breath for a sufficient length of time, or even that which results from a severe paroxysm of cough or sneezing. It should not, in any respect, be regarded as an epilepsy, as there was never any spasm or jerking of any description at the incipency or at any time during the attack.

4 GEORGE STREET.

CLINICAL OBSERVATIONS ON THE USE OF
HIGHLAND WATER
IN PUERPERAL ECLAMPSIA, PUERPERAL NEPHRITIS
AND THE VOMITING OF PREGNANCY.

By T. J. MCGILLICUDDY, A.M., M.D.,

SURGEON TO THE DISPENSARY AND HOSPITAL FOR WOMEN AND CHILDREN;
OBSTETRIC SURGEON TO THE NEW YORK MOTHERS' HOME MATERNITY HOSPITAL.

THERE is nothing more important in the art of preserving health, or in its restoration when once impaired, than that a careful consideration be given to the liquid needs of the body. Neither tea, coffee, beer, nor liquor are proper substitutes for water in the dietary; yet how many patients we meet who say they seldom, if ever, drink water! and their appearance bears out the truth of the statement, with their skins either wrinkled or bloated, pasty, yellow or eczematous, with muscles wasted, of costive habit, with hemorrhoids and pruritus ani, flatulence and pyrosis, with urinary tracts scalded by small quantities of dense, high-colored urine, and either gouty or rheumatic. They are the

* Read before the American Laryngological Association at its fifteenth annual congress.

class who furnish the mainstay to a physician's practice. I have seen numbers of such patients with a variety of diseases where I am convinced that their condition was in a great measure due to the fact that they drank little or no water. The liver and kidneys can not perform their important functions without a sufficient quantity, and, where liquids are wanting, the waste of the body accumulates, and rheumatism, gout, indigestion, and many other diseased states ensue. Patients do not, as a rule, take sufficient water, unless it is prescribed by the medical attendant; and in cases of gastro-enteric catarrh, where there is very frequently no thirst, a glass of pure spring water is often distasteful to them. They generally prefer some fermented liquor, or strong tea, or indigestible coffee. The aversion for water in these cases can be overcome, and the disease often removed, by prescribing it to be taken hot on an empty stomach, or before meals, and on retiring at night.

It is very important that the water supplied to patients should be pure and non-irritating. Waters heavily impregnated with mineral salts are not fit for constant use. Distilled waters have been largely introduced lately, but they are difficult of digestion and are unwholesome from the absence of the mineral salts that are found in solution in all natural waters. The *British Medical Journal*, in an abstract, says that Professor O. Liebreich, in a paper on Artificial and Natural Mineral Waters, read by him at the Balneological Congress recently held in Berlin, states: "There is a further reason for thinking that minimal quantities of substances in mineral waters may be of importance. The salt mixture forms a whole from which no part can be taken away without disturbing the equilibrium. This shows the fallacy of the old-fashioned notion that springs, the chief ingredients of which are the same, have the same therapeutic effect, even though differing in some minor ingredients. There is no analysis so exact or sensitive as our senses—taste and smell. A perfume of musk in the air is perceived by the smell, even though it can not be demonstrated by chemical analysis. Even the best manufactured artificial mineral waters differ from the natural ones in taste and value. This difference is not easy to explain; it is sometimes found, however, that two mineral waters, otherwise identical, differ as regards electrical conductivity. As to the so-called indifferent springs, it is a mistake to speak of them as of minor value. It must be remembered that they, too, contain mineral ingredients, if only in minimal quantities, which counteract the harmful properties of perfectly pure distilled water. Even hydropathy is a mineral-water treatment; for, if the water used were without traces of mineral substances, it would be poisonous. This has been sufficiently proved elsewhere." The foregoing was taken from the editorial columns of the *Journal of the American Medical Association* for June 17, 1893. Good spring water has all the following characteristics: It is tasteless, odorless, and colorless; soft and mild to the palate; it should contain no organic matter. The carbonates of sodium, potassium, and magnesium should not exceed twenty grains per gallon. In making a selection of mineral water these points should be well considered; and, if a patient is to drink it at a spring, the surroundings

should be pleasant and elevated, with diversified mountain scenery, and with an absence of humidity. Highland water from Maine fulfills all these requisites, and is consequently an excellent water for table and medicinal use. Sir Dyce Duckworth, professor of clinical medicine at St. Bartholomew's Hospital, London, in his recent treatise on gout, indorses this class of waters. He says they are of great value in cases of chronic and atonic gout; their action is diuretic, laxative, and tonic; therefore they are more indicated in many phases of gouty disorders than the waters of Vichy and Carlsbad.

Haig, in his work on uric acid, 1892, says these waters are the best solvents of uric acid, being far superior to lithia water, which causes a minus excretion; and Sir William Roberts, in his Croonian Lectures before the Royal College of Physicians, published in the London *Lancet*, July 16, 1892, said that the gouty should avoid waters with sodium salts in excess, like the Vichy and Carlsbad, and others, and that "there are other springs of high and growing repute, in the treatment of gout, which are not open to these objections," and he then indorsed very strongly these waters.

The mineral springs of the United States are equal to any in the world, and a knowledge of the composition of many of them is essential to the practitioner. Some of them are not to be used except in extremely rare instances. Oftentimes, as is the case with some of the Saratoga waters, the composition changes from year to year, being actively purgative one year and not even laxative the next; or they may, by the injudicious erection of hotels, dwellings, and stables about them, by percolation through the soil of sewage, become contaminated and show organic matter on examination. Being convinced that, in the treatment of acute nephritis, no diuretic is as efficient and safe as a pure, light, and soft spring water, I determined to use Highland water as being especially adapted for these cases. It is an extremely light and palatable alkalo-saline water, containing no lime and having a total of but a little over four grains per gallon of the carbonates of magnesium, sodium, potassium and iron, chloride of sodium, sulphate of sodium and potassium. At the New York Mothers' Home Maternity Hospital, in nine hundred cases of obstetrics, there were eighteen cases of puerperal nephritis observed and fifteen cases of puerperal eclampsia, in which Highland water was used as the principal remedial agent without a single death occurring; and whether the water alone, or its combination with other remedial measures, was sufficient to bring about this result I am not able to determine, but I am quite sure that the water was a very important factor. The mortality in eclampsia is generally rated at about thirty per cent. In puerperal eclampsia the blood is always in a devitalized condition as a result of the uræmic poisoning. In all of the above cases I gave freely of strong beef tea (made without fat), milk, and all the Highland water they could possibly drink. In some cases hot-air baths were given, and a teaspoonful of sulphate of magnesium was also given twice daily. For the control of the convulsions, chloroform was administered in some cases. The usual prescription for all patients was fifteen grains each of bromide of potassium and

chloral hydrate, given every two hours when needed, the first dose being sometimes double that quantity. The histories of several of these cases have already been published in the *Journal of the American Medical Association* for July, 1892. The cases of albuminuria of pregnancy were placed under the use of this water, with an occasional addition of a few other remedies, and a proper diet containing a lessened amount of starchy food; there was in all of them a complete restoration of the urine to the normal. The water seemed to be of especial value where the urine was scanty and high-colored. Besides its diuretic value, it is also useful in stimulating the functions of the skin. The disease being one causing great debility, the small quantity of carbonate of iron it contains, in combination with the alkaline salts, as recommended by Professors Flint, Thomson, and Draper, antagonizes the impoverishment of the blood which takes place. In promoting the urinary secretion it relieves the renal congestion. Only the mildest and blandest of diuretics are useful in these cases. One patient who came in, and almost immediately became unconscious, with repeated attacks of convulsions, and who was unable to take the water or any other treatment, except chloroform, died after a few hours. The following case of puerperal convulsions demonstrates the beneficial effect of Highland water in this disease:

Mrs. S., aged twenty-three, when seen before labor was found to have oedematous ankles and albuminous urine. In the morning, the patient having had severe labor pains during the night and the cervix being fairly well dilated, while I was preparing to use the forceps, she suddenly said: "I can not see; my sight has entirely left me," and almost immediately was taken with a genuine eclamptic seizure. A hypodermic of morphine was administered, the forceps applied, and a large child readily and safely delivered. She remained temporarily blind for several hours, and was seen by Dr. Charles H. May, who, after careful examination, found nothing whatever. There were no changes in the fundus except a slight cloudiness of the disc, which meant nothing. It was, I believe, a functional vasomotor paresis from disturbance of the retinal blood supply. After a few days the patient regained her sight; the albumin persisted in the urine, but under the administration of Highland water as a diuretic and a restricted diet, she made an uninterrupted recovery, the albumin completely disappearing.

This condition of puerperal amaurosis is an extremely interesting one. In the four cases I have had in my practice, fortunately the blindness has only been temporary. It came on at the time of delivery, or was noted soon after, with intense headache and other symptoms of acute puerperal nephritis. In all these cases the urine was highly albuminous. Patients with some degree of blindness are more common, and generally after delivery their recovery is rapid, the sight being completely restored in a few days. Two of my patients were extremely stupid and seemed to be in a partially comatose condition. None of them realized the gravity of their situation.

In the excessive vomiting of pregnancy we relieve portal and pelvic congestions, which are often the cause of this distressing condition, by removing hepatic engorgements and obstructions. This is best accomplished by the stimulating effect of hot Highland water taken an hour be-

fore meals and half an hour before retiring at night. Besides the use of narcotics and sedatives in this condition, a careful diet should also be enjoined, especially one quite free from an excess of carbohydrates.

TWO CASES OF LAMINECTOMY.

By H. O. PANTZER, M.D.,

INDIANAPOLIS,
PRESIDENT OF INDIANAPOLIS SURGICAL SOCIETY;
GYNÆCOLOGIST TO CITY DISPENSARY AND CITY HOSPITAL, ETC.

CASE I.—J. R., Alsatian, fireman, aged forty years. Four years and a half ago the patient was forced to jump thirty-five feet from the roof of a burning house. He landed on both feet and fell backward and to the right, remaining conscious until he was carried across the street, when his senses failed him for a few minutes. He had a tingling sensation in the spine and in both limbs continuing several hours with varying intensity, most severe and lasting in the right limb.

The patient was first seen by Dr. W. E. Jeffries, and then by the family attendant, Dr. Guido Bell, who has treated him intermittently since, and to whom I am indebted for the case and the supervision of the following history:

The first day the patient was very restless and hard to keep in bed. Once he eluded his attendant and walked across the room. He voided urine and feces voluntarily, without pain or admixture of blood. He had great pain in his spine, markedly in the lumbar region. A severe pain in both hips and inability to walk suggested a lesion about the hip joint. He had much thirst during the first twenty-four hours. On the second day movement of his body elicited intense "whirling" pain about the upper lumbar vertebra. Light rubbing relieved this for a time. This pain was constantly present for about a year. The patient rallied slowly, being able to walk only with difficulty and with pain in his back after several weeks. Three months after injury a severe coccygodynia arose, followed by a swelling like a bruise at the lower end of the spine. This pointed like an abscess but finally disappeared, without opening, under soft-soap anointment. Coccygodynia was present afterward whenever the patient got up after sitting awhile. His right limb was noticed to be numb, cold, and weak, and was dragged in walking. For a while he suffered nausea and spit blood. Later this ceased, and he passed blood from the bowels.

I first saw the patient two years after the accident, being consulted by Dr. Bell. The patient suffered acute pain in the coccygeal region. The sacro-coccygeal joint was found tender to the touch, and painful on passive motion. The coccyx was rigidly drawn to the right side. Pressure elicited pain and tenderness in a spot covered by a half-dollar over the upper lumbar vertebra. An examination under chloroform showed deflection of coccyx relieved, and no evidence of disease about the pelvis or rectum. The dilatation of the sphincter ani muscle gave permanent relief from the coccygeal pain. No more hæmorrhage from the rectum.

Ever since the accident the patient felt unsettled and restless, and seemed changed in his nature. His semblance to health prevailed on his friends to discredit his complaints of suffering and unfitness for work. He was repeatedly induced to take up light work, such as tower watcher and telephone attendant, without ability to endure. He was much afflicted with malaria, and had one attack of grippe. He had repeated attacks of weakness in the knee, and an increase of motor (extensor and adductor) paralysis of the right limb, being unable to bear the weight of his body on this limb. This aggravation of symptoms commonly arose in the springtime. At first it

lasted a few weeks at a time; last year about four weeks, and this year has lasted upward of three months uninterruptedly. In walking, the patient employed at first a cane; later, crutches were necessary. Intense occipital pain and pressure, often reaching forward to the right supra-orbital region and including the right ear, existed frequently. He often became confused and dazed; this was attended by burning of the eyes and difficulty in articulation. Recently these symptoms increased and he was irritable, querulous, and unjust. Severe pain and hyperæsthesia in the right inguinal region, at times accompanied with difficulty in breathing and nausea. Within the last year the right arm steadily grew weak, cold, and numb, and its painfulness interfered with sleep. *Petit mal* developed, starting with a peculiar sensation in the lumbar region. Usually the patient had time to call his wife before unconsciousness supervened. No twitching in these attacks. Pain in the right hip and limb, and attended with a prickling sensation, was constantly present though varying in degree. The right heel was hypersensitive. The patient was painfully sensitive to the concussion of a door slammed or of a heavy step crossing the room; "it would go right up the back." After retiring at night the right leg often jerked, continuing for an hour. Repeatedly the muscles of the back and abdomen participated. The sexual function remained unimpaired throughout; it effected fecundation twice since the injury. For a while the sexual appetite was increased. Frequently, even when at his best, after sitting quietly for a while, on attempting to get up the patient found himself without the use of the right limb for a period of five minutes; "it felt not like numbness nor like sleeping."

For a while the patient felt the muscles of the limb were too short, or as if they were clothed in wet hose; he never had the sensation of a cord around the body. Various doctors and remedies were tried in time. Blistering of the spine, hot mineral bathing, electricity, nerve sedatives, etc., were tried without effect. A jacket of plaster of Paris or leather was worn during the last two years and gave him comfort, though no cure.

The patient was referred to me a second time in May, 1892, by Dr. Bell, who suggested the propriety of surgical treatment. The symptoms were steadily increasing, physically and mentally. Crutches were necessary for locomotion; the right limb could not bear the weight of the body, owing to the extensor paralysis; the limb was dragged in walking. While sitting he could not cross his right limb over the left without the aid of his hands. Sitting, the patient is most comfortable in an arm-chair and resting on his right side and elbow. His sleep is heavy, dreamful, and unrefreshing. He takes neither alcohol, tea, nor coffee. The appetite is diminished. Pressure on the vertebrae elicits great tenderness over the spine and the articular processes of the second lumbar vertebra, and evokes cries, and contraction of the muscles of the spine and the right limb and arm. The tactile sensation in the right limb is blunted, extending anteriorly and posteriorly down to the foot. The head of a pin is felt like a finger. Temperature is less than in the left limb. The difference of the calves is an inch and a fourth in favor of the left limb. The right thigh is correspondingly less in size, the atrophy including the extensors and adductors. In the right limb the patellar reflex is increased, the palmar reflex diminished; both are normal in the left. There is no coxalgia. The right arm is atrophied, cold, and weak; patient can exercise no grip power. He stammers, pauses, and enunciates with difficulty. The tongue is movable in all directions. There is no facial paralysis. Pupils are unequal; the right is dilated excessively; this remains unchanged during an observation extending over several weeks; this condition was not noted by the former attendants.

Diagnosis.—Fracture of the lamina and the articular processes of the right side of the second lumbar vertebra; compression of the cauda at this point. The *petit mal* and the other cerebral symptoms are regarded reflex to the compression of the cauda. The progressive ascending spinal symptoms are held to be owing to a unilateral ascending myelitis.

The operation was proposed as being alone available after all other measures had failed, and because the condition had become unbearable and was threatening an early end. Doubts about its efficacy were entertained on the long duration of the spinal compression, four years and a half having elapsed since the injury, and owing to the ascending myelitis. Restitution *ad integrum* seemed improbable, if not impossible.

The patient gladly consented to this proposition, and was operated on at my sanitarium on June 15, 1892.

Dr. Bell administered chloroform and Dr. E. C. Reyer assisted. The patient was placed on Edebohls's laparotomy table with the anterior surface of the hips resting on the end of the table, which was raised as in Trendelenburg's posture, the head of the patient on the forward end of the table and the limbs hanging over the lower end. A rubber bag partially filled with water acted as a cushion between the anterior abdominal wall and the table. This position gave the greatest convexity possible to the lumbar region and proved of great service in exposing parts. I had experimented with this position and found it tenable without great discomfort or any respiratory embarrassment. An incision six inches in length was made directly over the spines of the lumbar vertebrae. The soft tissues were severed with the scalpel, closely hugging the lateral surfaces of the spinous processes on each side, cutting from above downward to sever the tendinous attachments of the upper muscular layers, and from below upward for cutting the deep layers. This I found practical to save unnecessary mutilation of the soft parts; it is suggested by the anatomy of the parts. The right and left laminae of the second and third and the right of the fourth and part of the right of the fifth lumbar vertebrae were removed. The right lamina and the articular processes of the second vertebra were found thickened from a longitudinal fracture through these parts. Part of the articular processes required removal. The dura mater was found thickened and adherent in this part, and was torn open in removing the cut fragments of bone. A piece of the dura about a fourth by half an inch was removed. The venous bleeding resulting was temporarily frightful, but easily controlled by a gauze packing left in place a few minutes while the work was continued on the opposite side of the spine. Pulsation of the dura was visible. A slight deflection of the third and fourth lumbar spines revealed that these had been broken and reunited by ligamentous union. The right lamina of the third vertebra was contracted and bulged outward (backward) and the articular processes were thickened. The unilateral removal of the lamina of the fourth and fifth vertebrae was done solely to make ample opening. The experience from operations for the relief of compression of the spine calls for free opening. The analogy between the skull and the spine makes this rule applicable to spinal surgery (Chipault).

Drainage was procured with rubber tubes and a skein of silkworm ligatures on each side of the spines. Silkworm was used for suturing the wound. The wound was covered with sterilized gauze and cotton, held in place by adhesive strips. The anæsthesia in the described position was well borne, the operation lasting over two hours. The temperature before the operation was 97° F.; pulse, 62; on leaving the table the temperature was 96.8° F.; pulse, 64. Little nausea and no vomiting followed the anæsthetic. Feeding was resumed on the second day. The considerable oozing of sero-sanguinolent fluid

during the next three days required frequent changes of the dressing. The rubber drainage-tubes were removed on the second day, the stitches on the seventh day, when the parts were healed, except above and below, where the drain openings still existed.

The temperature during the first week reached 100° F., probably owing to an absorptive fever in consequence of the contusion by the retraction of the tissues during the operation. During the attacks of pain it ran up 0.5° to 1° F. After the first week it was normal or even a few tenths subnormal. The pulse varied between sixty and seventy beats to a minute all the time except during pain, which ran it up ten to twenty beats. The urine was voluntarily and easily voided from the start. A slight irritability of the bladder developed on the second day and lasted two days, during which time the urine was voided at intervals of one to two hours. Otherwise vesical symptoms did not obtain. The bowels moved normally. Numbness in the right limb was less on the morning after the operation. The limb was normally sensitive within another day, and on the fourth day and until three weeks had passed it was hypersensitive to the touch, markedly about the knee joint, on the inner side of the thigh, and the upper half of the outer side of the thigh. The right inguinal region was no longer sensitive to pressure after the ninth day. Great pain in the afflicted side (limb, inguinal region, arm, and occiput) within twenty-four hours after the operation. It was variably present for four days; then it recurred on sundry occasions in single regions, and was quite absent after two weeks. There was pain in both eyes on the fourth day. The pupils were noted to be equal on the sixteenth day, unequal on the twentieth day, and lastingly equal after the twenty-first day. The patient, who is naturally excitable, was restless following the operation and quite hysterical. Morphine, one quarter grain twice daily, was given two days, then bromide of sodium was substituted. No natural sleep occurred until after two weeks. On the fifth day the patient was able to cross the right limb over the left without the aid of his hands. The right hand had regained its grip within the first four days. On the twenty-seventh day a leather jacket was applied, and the attempt to sit up and walk was first made, and it succeeded. The right limb bore the weight of the body without strain, and the patient sat up ten minutes. On the next day this attempt was repeated. A tingling sensation in the right knee occurred on standing up. On the twenty-ninth day the patient was up most of the day. On the thirtieth day he walked down a flight of stairs, crossed the street to a barber's shop and returned, without assistance or crutches. One week later the patient was presented to the Indianapolis Surgical Society. Since then he has remained well with one exception. Six months after the operation, incidental to financial grievances and complicated with malaria, the patient developed fever and a delirium of one day's duration. This was unattended by any return of the former symptoms, and may hardly be connected with the former disease.

This recalls an attack of hysterical delirium which he developed on the nineteenth day after the operation. He had clandestinely made a half-hearted attempt to walk and failed. This evoked wild grief and fears. I did not know of this venture, and could not construe the cause of the hysteria; neither could Dr. Bell, whom I called in at this time. Patient did not give me this information until some time after his recovery was assured.

The difficulty and risk of an operation on the spine call for a thorough consideration of its indications. Quite a number of recent writers on this subject, among them authors of standard text-books, condemn all spinal operations

without condition. This serves to emphasize the importance of accuracy in diagnosis. Unfortunately, the symptomatology of injury and of disease of the nerve tissues is intricate and variable, and involves great uncertainty in locating the seat and nature of the lesion. It is often quite impossible to discriminate between lesion of the cord following injury, and lesion of its membranous or osseous envelopment. It is often impossible to determine immediately after an accident causing fracture and dislocation of the vertebræ and attended by paraplegia, whether the cord is compressed only, or crushed beyond restitution; much less to make finer distinctions.

The case reported here is illustrative of the difficulty attending diagnostic precision, and affords an uncommonly interesting material for clinical study and practical deduction. I wish briefly only to allude to this here, because belonging more properly to the domain and decision of the neurologist than to the general surgeon. The operation developed the existence of more fractures of bone than previously were diagnosed. Indeed, before the operation there was little evidence of fracture having occurred. In fact, the right lamina of the second and third lumbar vertebræ, and the spines of the third and fourth, were found to have suffered fracture. This demonstrates the difficulty of recognizing this form of lesion. The heavy muscular coating and the deep seat of the vertebræ serve well to cloud fracture in this locality. No doubt fractures of the vertebræ are a much more frequent accident than commonly accepted, both after force directly and indirectly spent. It is safe to say in a given case, when dislocation, crepitus, undue mobility, etc., are present, that there is a fracture. Hardly may we ever definitely assert in the absence of such symptoms that there is no fracture of the vertebræ.

By the lesson of this case we may feel justified in suspecting many cases of so-called traumatic hysteria, traumatic neurasthenia, traumatic lumbago, concussion of the spine, spinal irritation or anæmia, hemorrhagic pachymeningitis, chronic leptomeningitis, to develop their symptoms on the basis of a vertebral fracture, with or without injury of the membranes, and making pressure on the cord. The presence of deformity, ever so slight, must needs suggest the possibility of its causative relation to the spinal disease, and call for the consideration of surgical measures when other means have failed. The history of many cases shows that a deflection and deformity of the spine have been noted—cases that were unyielding to other treatment, and whose symptomatology suggested a similar pathology as in Rubin's case. This condition in individual cases may yield the indication for operative procedure.

Traumatic lumbago, or railway back, seemed a justifiable diagnosis from the pain in the back, increased on motion, and on transmitted shock; the reflex spasm of the spinal muscles, the rigidity of the vertebral column, following the pain; muscular tenderness in the affected region, and from the absence of apparent fracture of the vertebræ.

A unilateral ascending and descending myelitis, and a peripheral neuritis, in the accepted obscure definition of inflammatory conditions of the cord and nerves, as a development consequent or subsequent to injury, might have

been accepted to exist here. Much contained in the current literature under the head of traumatic nervous diseases may be construed to be similar in origin with this case.

Modern pathological researches have clearly settled and defined the separate nature of traumatic insult and inflammatory agent. Barring self-infection, which is rare and ordinarily pertains only to individuals of a weakened and diseased constitution, compression or injury of the cord is not followed by inflammatory action. The writings and laborious investigation of Page, Watson, and others have done much to explode the notion, long held and yet not fully abandoned, that nervous tissue marked an exception to the rule by inflaming after injury, irrespective of infection. Compression myelitis is a term still in honor, yet in conflict with rational nomenclature and pathology. Knapp makes a just accusation when he says: "Among the sources of confusion in regard to traumatic nervous affections we must certainly recognize the mistakes in nomenclature, etc."

It is reasonable to say, looking back on the case under consideration, that from *a priori* reasoning, as well as from the immediate and complete resumption of functional activity, there had existed in this case no inflammatory disease, no myelitis, nor peripheral neuritis.

This brings up the consideration of what was the pathology? It is certain a compression of the cauda existed. Did this give rise to an ascending and descending degeneration, or to neurasthenia along certain courses? Was it owing to an irritation, transmitted upward, downward, or toward the periphery? Was it an atrophy, or a functional disturbance by defective transmission, or reflex excitation? However the answer may read, it is interesting and important to note that four years and a half had passed from the time of the injury to the date of the operation. It appears from this that an inference on the remediable character of the affliction can not be drawn from the duration of the disease. The ilio-inguinal neuralgia can have meant no neuritis, though clinically it might have been accepted to exist. (Knapp.)

The insidious nature and the slow development of the symptoms are commonly indicative of the spinal cord being exempt. Excepting where acute paraplegia, local paralysis, and anaesthesia exist, the cord may be regarded non-injured.

Whether this case tended to death may be questioned, but this seemed probable. The point bears interestingly on the question whether so-called traumatic neurosis can produce death.

The case is interesting by the presence of obstinate cerebral symptoms, which yielded more or less immediately after the operation. They might have been judged to be an independent cerebral affection. They probably were reflexes. It is of interest, by comparison, to quote Starr, in the *American Journal of the Medical Sciences*, July, 1892, who, speaking on the diagnosis of lesions of the cord, says: "In spinal affections we always have the face as a convenient surface with which to make comparisons; and in diseases of the lower region of the cord, to which attention is direct-

ed in this paper, we have the arms and trunk as a standard of normal feeling."

The absence of vesical and rectal symptoms indicated that the lower sacral region was free of disease (Starr). The sacral nerves showed increased excitability, expressed in pain, sphincter spasm (constipation), bleeding from the rectum, muscular rigidity, pain (coccygodynia), and increased sexual appetite. The hæmorrhages, in the absence of rectal disease, were owing, probably, to vaso-motor reflexes. The motor and sensory disturbances pointed to the upper lumbar regions being the seat of the trouble (Starr).

Knapp (*American Journal of the Medical Sciences*, December, 1892), in an article entitled Traumatic Nervous Affections, reviews this subject in the light of ninety cases observed by him. I quote from him: "The chief complaint is of weakness and stiffness in the legs and of pain in the back, the latter being often due to traumatic lumbago. The knee-jerks are somewhat exaggerated and sometimes there is ankle clonus. One or both legs may show some muscular atrophy, usually without electrical changes. There is often some pain in the legs and various perversions of sensibility, but anaesthesia is rare. Disturbances of micturition are not often uncommon; the demand is often imperative, and if it be not immediately gratified there may be a little incontinence; sometimes, too, it is hard to start the stream, or it stops before the bladder is fully emptied. Constipation is common, and sometimes the anal sphincter in moments of imperative need yields involuntarily. In these cases the clinical picture resembles somewhat that of spastic paralysis, and autopsies and experiments on animals have shown the most marked changes in the lateral columns. Cerebral symptoms are absent and everything points to a spinal origin."

Knapp reports four such cases, and says while some writers deny the possibility of such cases, he will critically examine their arguments by a more elaborate study of such cases. Rubin's case is interesting in affording a remarkably similar symptomatology, and by the results of the operations justifies conclusions quite opposite to those drawn by Knapp. The symptoms do suggest spinal-cord lesion, and still it did not exist.

The possibility of its purely hysterical nature, psychical origin, should be considered yet. The French school will probably at once decide it to be such. This seems hardly justifiable after finding positive evidence of spinal compression. Then, too, the previous plans of treatment (stretching the sphincter under chloroform, plaster-of-Paris jacket, blistering, etc.) were undertaken with expressed confidence of a cure, and were designed to take psychical effect more than the slim hopes held out to the patient by an operation. He was informed that this might kill or fail of all results, even leaving him worse than before. Even after the symptoms had yielded in great part, but before the patient was allowed to get up, he was told that possibly on the resumption of the upright position all the former troubles would return, and, in consequence of the changes in the parts by the operation, greater weakness and worse symptoms might appear. This was done to avert the otherwise crushing despondency after a failure.

To sum up, the lessons of this case would seem to be—

1. To emphasize the obscurity of spinal disease.
2. The uncertainty of ascertaining the nature and regional extent of the lesion.
3. The impossibility of determining beforehand the degree of destruction and its relation to the power of regeneration.
4. The possibility of compression so closely resembling other lesions as to represent them all.
5. The uncertainty of diagnosis where it is coupled with failure of therapeutical effort otherwise should call for the earnest consideration of an operative venture.
6. The position during operation afforded advantages that may induce further adoption of it.

The recovery from the spinal and cerebral symptoms in Rubin's case was and remains complete at this writing, thirteen months after operation. A stiffness of the lumbar region is present, and it is owing to an ankylosis resulting from the operation and prolonged splinting. It can only be conducive to support and protect weakened parts. It disables the patient as regards lifting anything heavy when his body is bent forward. The jacket was worn two months after the operation and then dispensed with entirely.

CASE II.—W. R. McG., American, fireman, aged forty years. In March, 1890, the patient stood on a burning roof, which suddenly gave way at a height of about thirty feet. He was found standing up, stunned and dazed. He showed great excitement, and, on being taken home, grew hysterical. He was inordinately jocular; claimed to suffer no injury or pain. He reported for duty the next day. Soon it was observed that his memory failed him and that his speech often was incoherent. His limbs twitched, and on getting up he would stagger a little before he could walk. He complained of backache and rheumatic pains in his limbs; was irritable, in contrast to his former calmness and cheerfulness of manner. His speech was muffled and by an effort varying in degree. These symptoms were noted by his fellows in the fire department, who tolerated his condition and assumed his duties to enable him, nominally, to be enlisted for duty. Constipation existed before the accident, but was greater after it. He sobbed and cried in his sleep. He scratched his head sore back of the right ear and picked his nose much. He was stupid a great deal of the time; would sit musing and laugh to himself. While walking at times his right knee would yield under him; every time he got wet there would follow pain and weakness in the right limb. In walking, the patient bung forward and to the left. He was cheerful about his condition, thought little about it, and always expressed himself confident that he would get well again. In July, 1891, the patient was knocked over by a hose, and fell with his back on a projecting board. Since then he complained much more of backache, and his limbs pained him, especially the left. Rubbing them would temporarily relieve this pain. He felt much better when sitting down, and was much relieved in the morning after a night's rest. He was off duty since the last accident. In February, 1892, the patient was suddenly seized with a profound stupor. He was dazed, could not talk, nor would he answer to questions. He had great pain in the head and body, and was restless and sleepless. The next day his gait was staggering and his speech more difficult and unintelligible. Two more such attacks occurred within six months. Of late the patient is less excitable. His appetite is always good, digestion perfect. Sexual desire lessened gradually until lately, when impotency prevailed. I saw the patient Novem-

ber 3, 1892, two years and a half after the first accident. The right limb bears the weight of the body unsteadily. The right thigh measures nineteen inches and three quarters, the left thigh twenty inches and a half. The right limb is not full on the inner side like the left. The knee reflexes are diminished, more on the right side. There is no disturbance of sensation to touch, prick of pin, to heat or cold. A blunted sensation only exists in the upper and back part of the right thigh and part of the leg. In standing, the patient always favors the right limb, and in walking he leans and shifts to the left side. In the right limb the extensors and adductors show weakness. There is difficulty in passing urine now and then, more so of late. The right hand is less strong than the left. The spine is sensitive to pressure at the lower lumbar vertebrae; the spine of the fourth is deflected three eighths of an inch to the right side. The dorsal spines are tender and deflected to one side. The right pupil is dilated and stationary; this condition is ascribed to an injury to the eye many years ago, since when it is unchanged.

I saw the patient again December 4, 1892. The day before he had had three attacks of sudden weakness. In the last attack he was shaving himself, when a cramp of the right arm and hand occurred. He turned around to tell of this, when he sank down in his knees. Consciousness was retained. The speech was limited to saying Yes and No indistinctly, though he evidently cared to say else. The right limb is perceptibly weaker than before; the right arm is cramped, especially in the little and ring fingers, which, too, are painful. Two doses of bromide of sodium, fifteen grains each, relieved the paralysis of the arm and the speech only. Stupor, or daze, continued worse than before.

The history and the symptoms in this case hardly justified a definite diagnosis. The symptoms probably were of both spinal and cerebral origin. The occurrence of a second accident complicated the interpretation of this case very much. It could not be ascertained whether the deflection in the lumbar spine existed consequent to the first accident. If this had pre-existed to the second accident, it would have been right to assume that the symptoms, at least in part, were owing to an injury of this region. From the history as given, the symptoms had increased since the second fall; a clear description could not be given of the chronological succession of events. The case was perplexing in its reading; it was growing steadily worse. The experience in the previous case, recalling great similarity in the nature of the accident, the circumstances attending it, and the symptomatology, naturally suggested the consideration of an operative recourse. An operation afforded no valid promise. The case every way seemed worse and more obscure than Case I. Medical treatment, electricity, stiff jacket, and extension, all had been tried without benefit. The patient had been under the treatment of Dr. William B. Fletcher, who regarded the affection of spinal origin.

The case in its obscurity and prognostic gloom, even by an operation, was fully presented to the family. Operation was not advised, though offered, if requested. The case was under advisement three months, when operation was called for.

Operation at my sanitarium on December 20, 1892. Dr. W. J. Browning gave chloroform; Dr. Bell and Dr. Reyer assisted. The position and procedure as in the former case. The spine of the fourth lumbar vertebra was found fractured and united by ligamentous union; its right lamina was thickened and bulging. The laminae on both sides of the fourth and fifth lumbar vertebrae were removed. Slight dural adhesions were found. The dura was opened and nothing indicative of caudal disease was found.

The patient bore chloroform well, and no vomiting fol-

lowed. The temperature after the operation was 98°; pulse, 94. Feeding was well borne. He answered to questions and described his complaints. He was altogether more restful than the former patient at this stage. At 7 p. m. of the second day hicough developed, and pain in the interior half of the thighs. At midnight the patient grew restless. He wanted to get up, and was restrained with difficulty. Morphine, one fourth grain, was given at two o'clock, and thirty grains of bromide of sodium half an hour later, with the effect to quiet him. The patient perspired freely and his pulse ran up to 140.

At six o'clock that morning the temperature was 100.2°, pulse, 104. At 11.45 a. m. the patient suddenly stopped breathing for about two minutes (nurse's statement), and limbs twitched, more on the right side. When I saw him shortly afterward his temperature was 101°; pulse, 124; respiration, 30. He was in a stupor from which he could not be roused. The face was drawn to the left. Temperature steadily fell, pulse increased, the respiration increased in frequency and became stertorous. Death occurred at 7 p. m., fifty-five hours after the operation. The wound had been dressed twice, was sweet and free of suppuration, swelling, or redness; there was less sero-sanguinolent discharge than in the former case.

A post-mortem examination had to be limited to the seat of the operation and developed the parts free of redness, swelling, or pus. The parts were agglutinated, except where the drainage-tubes interfered. The dura and cauda were free of congestion.

It must be regretted that the post-mortem examination did not cover more ground; by the light of it alone might this case have a clear reading. It is likely that diseased conditions higher up on the spine were at fault; and cerebral complications may be accepted to have existed. The final scene must probably be connected with a lesion, an apoplectic seizure, located in the medulla oblongata, and was like in kind to the attacks he had previously suffered. The operation can hardly be accused of more than an exciting cause, added to an explosive condition pre-existing.

194 EAST MICHIGAN STREET.

ORGANIC STRICTURE OF THE ŒSOPHAGUS.

By PRICE BROWN, M. D.,

TORONTO.

EXCLUDING dysphagia produced by external pressure, the two recognized forms of organic stricture—fibrous and malignant—are often difficult to diagnosticate from each other. This is more particularly the case when the former variety, like the latter, occurs in middle or advanced life, and where it can not be traced directly to traumatism. The fact that the symptoms of fibroid stricture so closely resemble those caused by the first stage of cancerous disease has caused many to believe that the two are really identical, and that the presumed fibrosis is merely an indication of the presence of malignancy.

That idiopathic fibroid cases do occur, however, seems to be borne out by the literature of recent years, as a number of cases have been published in which there was no apparent tendency to formation of cancer, and yet in which the etiology of the existing fibroid lesion could not be traced.

In view of the idea of identity, the question might be

asked: If non-traumatic stricture of one mucous membrane—the urethra—be rarely if ever malignant, why should non-traumatic stricture of another mucous membrane—the œsophagus—be always malignant?

When marked malignancy exists the symptoms are characteristic enough. We have the cancerous cachexia; the enlarged glands; the roughened, jerky, hæmorrhagic mucous membrane on passing the bougie; the pain; the fœtor; and the speedy invasion of the larynx or trachea; in contradistinction to the clearer complexion, the absence of glandular enlargement, the smooth but tightly grasping œsophagus, the freedom from hæmorrhage, and the normal larynx of the fibroid. Still, without doubt, many with simple fibroid symptoms at first, ultimately take on all the distressing features of malignancy.

The treatment of fibroid stricture should aim essentially at restoring, as far as possible, the normal lumen of the œsophagus; and as a supporting measure, with the view to prolong and make comfortable the life of the patient, the same should be our object even when the disease is of a malignant nature.

Some enthusiastic abdominal surgeons have, however, taken a different view; and, perhaps with more force than wisdom, urge the importance of the operation of early gastrostomy in all cases of undoubted organic stricture. A brief examination of published cases will be sufficient comment upon such a method of procedure.

In looking up the literature of recent years upon stricture of the œsophagus, I can only find records of 49 cases.

Of these, 29 reported as malignant, 13 as fibroid, 2 as traumatic, 1 as syphilitic, 2 as unclassified, and 2 as paralytic.

Of the patients with malignant strictures, 11 were treated by linear electrolysis and dilatation, with reported good results; 9 by gastrostomy, of whom 5 died within fifty hours, 3 lived short undefined periods, 1 lived 3 months and died of lung complication; 8 were treated by retention tubes with beneficial results, and 1 was treated by œsophageal bougies with beneficial result.

Of those with fibrous strictures, 8 were treated by linear electrolysis and dilatation, with 7 cures; 3 by retention tubes, all cured; 1 by dilatation with bougies, cured; 1 by gastrostomy, died two days later.

Of the traumatic, 1 was treated by gastrostomy, cured; 1 by dilatation with bougies, cured.

Of the syphilitic, 1 was treated by dilatation, cured.

Of the paralytic and remaining cases no report is given.

As will be seen, no case of permanent cure of malignant stricture has been recorded, while the only ones in which the treatment has been followed by an immediately fatal result have been those in which gastrostomy has been performed, or in fifty-five per cent. of the patients operated upon.

Two or three of the more remarkable cases of gastrostomy might be referred to more fully.

In Sheen's* case a hard, cancerous nodule occupying

* *British Medical Journal*, June, 1889.

the circumference of the tube was found, through the center of which a No. 10 catheter could be forced. There were no enlarged glands, yet patient died the following day.

In Ross's* case, the patient was fifty-five years old. His state was that of almost complete inanition. He died two days after operation. There was no glandular enlargement, the case being one of simple fibrous stricture near the lower end of the oesophagus, and too far down to admit of successful dilatation. The surgeon believed that an earlier operation would have saved his life.

In Terillon's† case—one of cicatricial stricture—it was impossible, both before and after gastrostomy, to catheterize through the pharynx. It was possible, however, to pass a catheter from below upward; and from this the permeability of the oesophagus gradually became established. The stomach fistula was finally closed, and the patient could swallow as well as ever.

The cases of linear electrolysis are all reported by A. Fort,‡ who has proved himself an enthusiast in this line of treatment; and a singular success seems to have attended his efforts. As no fatal results have occurred directly from the treatment itself, it is worthy of a more extensive and thorough trial.

Symond's* retention tubes and Leyden's|| permanent cannulas in malignant cases, the stricture being situated in the neighborhood of the larynx, have met with more general favor. In Annandale's^ fibroid case, swallowing fluids prior to the insertion of the tube could be accomplished with great difficulty. Subsequently he took his meals with pleasure. In Lodge's() malignant case the tube was worn seven days. The patient took food well and gained four pounds in the time. Then the instrument choked up, had to be removed, but could not be reinserted, and the patient died. In his fibroid case the tube continued to be worn with advantage.

In four out of the forty-nine cases reported was the dilatation method practiced. In the three non-malignant cases cure resulted; in the malignant one, marked relief.

Morejon's‡ first case was one of double traumatic stricture—the one situated at the diaphragmatic ring, the other at the level of the first dorsal vertebra, both produced by a large needle at the age of eight years. Treatment was by dilatation fifteen years later. The result, permanent cure. His second case was extensive fibroid stricture. The treatment, daily catheterism for forty-five days, likewise resulting in cure.

Kemp's§ case was one of syphilitic ulcer in a woman aged thirty-six, situated four inches down the oesophagus; successfully treated by bougies.

Revington's* was one of malignant disease, and, as already stated, the result was temporarily beneficial.

To these I may add the three following cases, which came under my own observation during the present year.

CASE I.—Mr. J. C., of Fenelon Falls, aged sixty-two years, bookkeeper, referred on April 5th. Family history good. Personally healthy until three months ago. Symptoms then commenced with pain in one ear and in swallowing. Always spare; had lost twenty pounds in that time. Dysphagia had increased steadily since January, but not the odynophagia. During the last twenty-four hours had only been able to swallow half a tumblerful of soft food. To test the power of deglutition I gave him a mouthful of milk to swallow. It produced a spasm of strangulation and came back through the mouth and nose.

Glands of left side of neck slightly swollen. Throat catarrhal, but larynx normal. After washing out the throat with a spray I attempted to pass larger bougies down to No. 9 catheter, but in vain. Could only get the smallest down to the region of the cricoid. Finally I wrapped a laryngeal probe with absorbent cotton, and saturating it with a ten-per-cent. solution of cocaine, succeeded in passing it through the stricture immediately behind the cricoid. There was some jerking and roughness, but no hemorrhage. It took several minutes' gentle pressure to pass it through. I followed this by No. 9 catheter. After waiting a few minutes I repeated both operations. On the 6th, at 9 A. M., passed No. 11 catheter; at 7 P. M., No. 13 bougie. On the 7th, No. 15 bougie; on the 8th, No. 17 bougie; but on each occasion I had to precede the bougie by the cocaineized cotton probe. My bougies were all round-pointed; I had no tapered ones. It seemed as if the roughened, swollen, internal surface of the stricture filled up its lumen, and it was only after the astringent and anæsthetic effect of the cocaine that the instrument could be entered. For the next seven days the routine of probe and No. 17 bougie were regularly performed. On April 14th† I secured a tapered No. 22 oesophageal bougie, and for the first time was able to pass the instrument without the previous use of the cotton-holder.

After this the intervals of treatment were lengthened to several days. The patient became quite hopeful and could take a fair amount of food. He returned home, taking the bougie with him; and, at my request, his physician, Dr. Graham, continued to introduce it two or three times a week.

On June 15th, ten weeks after I first saw him, Mr. C. returned for examination. He looked stronger, took all the food he wanted, and had gained one pound in three weeks. The doctor had not passed the bougie for ten days. Notwithstanding all this, the glands on the left side of the neck were more numerous and larger; the left arytenoid, formerly unaffected, was swollen and red, and the left vocal cord was paralyzed and in the cadaveric position. He remained several days, during which time I introduced the large bougie a couple of times, with slightly more difficulty, and attended on the first occasion with slight hemorrhage. Near the last of July I received word that, although he was slowly failing, his capacity for swallowing had even improved, and two weeks had elapsed since the doctor had had to use the bougie.

This case is undoubtedly malignant and must soon terminate fatally; still the advantage derived by the patient from the treatment could not be questioned.

CASE II.—Mrs. B., of Princeton, aged fifty-two years, referred on May 16th, has had difficulty in swallowing for a long

† On the 13th the patient was exhibited and bougies were used before the Toronto Medical Society.

time, becoming steadily worse for the last two years; can assign no cause for it. Is thin and nervous; can swallow fluids slowly, actual solids not at all, and pulp only in small quantities. No external swelling. Pharynx and larynx normal. Upper œsophagus catarrhal.

After spraying with cocaine, introduced No. 15 tapered bougie. It passed smoothly down the œsophagus, but was grasped tightly at the region of the cricoid. On the 17th passed No. 17 bougie. On both occasions soreness was produced, extending up back of neck toward the occiput. On the 18th and 20th passed No. 19 bougie; soreness less marked. The patient went home, returning for treatment on June 2d. Deglutition much improved. After spray of cocaine, passed No. 22 tapered bougie without much difficulty. On the 3d passed same without cocaine; likewise on the 6th. Returned again on the 13th, eating well and free from pain. Passed No. 22 bougie; followed this by egg-shaped dilator No. 25. Had more difficulty with the latter; but as it passed through stricture, it dropped suddenly into the wider passage, indicating the precise extent of the lesion. Its extraction was still more difficult than its insertion, and on this account would seem to be a more dangerous instrument than the œsophageal bougie. Three weeks later I again inserted the No. 22 bougie—this time without the slightest difficulty. Patient felt well and strong, and since her last visit had taken her meals with the rest of the family.

This, I think, may be regarded as a case of idiopathic fibrous stricture, with a prospect of complete recovery.

CASE III.—Mrs. D., of Brantford, aged sixty-six years, referred on June 21st, has been failing for two years. Has suffered for a long time, off and on, from diabetes insipidus. Also has had glandular swellings under the ribs and arms. Now has them in the neck; can not swallow solids, fluids only in small quantities. Case considered by family physician as a hopeless one of malignant disease.

On examination, no cancerous odor, no marked cachexia. Larynx normal; supersecretion from the lower pharynx; expectoration profuse.

Could not pass the smallest bougie more than two inches below entrance to œsophagus. On the 22d failed again to pass small tapered bougie below the cricoid. As the soreness was considerable, did not attempt again until the 24th. This time I adopted the plan referred to in treatment of first case. Dipping the cotton probe into a ten-per-cent solution of cocaine, I carefully passed it down the œsophagus and into the stricture, using gentle pressure. In a few minutes it passed through. This paved the way for No. 15 tapered bougie. On the 26th the probe was again used; this time followed by No. 17 bougie. On July 3d patient returned to my office improved in every way. She had taken nourishment fairly well, and, for the first time since I had seen her, walked about without assistance. After spraying with cocaine, I introduced No. 22 tapered bougie. It was grasped tightly but penetrated without much difficulty. On the 7th introduced same instrument again, without using cocaine and with still less difficulty.

Two days later, as she was taking nourishment freely and without pain, she left with friends to recuperate at the seaside.

This case is a less hopeful one than Case II. and may prove to be malignant. Still it lacked the characteristic odor, the attendant hæmorrhage, and the roughness of surface usually attending that disease; and the treatment was rewarded by the gratitude and approval of both the patient and her friends.

The œsophageal bougie in unskilful hands is undoubtedly a dangerous instrument; but when manipulated with proper gentleness in selected cases, its use may often be attended with the best results. Quite possibly the reason why it has not

been received with more general favor is that the use of cocaine, applied internally to the stricture itself, has not been practiced.

37 CARLTON STREET.

A CASE OF UNILATERAL MEMBRANOUS RHINITIS.

By JOHN DUNN, M. D.,
RICHMOND, VA.

TOM S., aged five, was brought to my office June 5, 1893. History as follows: Two weeks ago patient had amygdalitis. Since the acute symptoms subsided patient has been "threatened several nights with the croup." Has had "cold in the head, which has stopped the nose up, so that I have had to wash it out before he could breathe through it." Child since infancy has had croupy tendency. During the attack of amygdalitis patient had "white patches on the back of his throat." Quite a severe attack of croup the night of June 2d. Family physician was sent for June 3d, and, having his attention drawn to the nose, found protruding from the left nostril a whitish semisolid substance. Thinking it might be a mucous polypus, he attempted to remove it, but found that it bled with the slightest manipulation. The little patient at this time seemed to be well—"no quickening of the pulse," "no fever." Examination of the throat June 5th showed moderate enlargement of the tonsils and some adenoid tissue, together with some signs of pharyngeal inflammation. No membrane. The right nostril and nose were clear, except for the presence of some loose mucus. The left nostril was entirely occluded by a thick, tough, whitish membrane. The nostril entrance was swabbed with cocaine solution, and the membrane was then seized with a pair of forceps and an endeavor was made to withdraw it. A small piece was torn from the cartilaginous septum. This was followed by considerable bleeding; perhaps a teaspoonful of blood followed this attempt. With some manipulation I found that the membrane extended back far into the nose, and was on all sides attached. After applying cocaine thoroughly to the nose, a warm solution of bicarbonate of sodium was sprayed into the nose for about a minute. The patient was then told to blow his nose. He did so, but complained that it hurt him to blow it. The spray was again sent into the nose, and after two or three minutes the patient was told to again blow his nose. He did this two or three times, when finally the membrane came away entire. The denuded surface of the nose could then be seen. The membranous attachment had been to the lower half and anterior two thirds of the septum. A posterior deviation of the septum seemed to be its limit behind. It was attached also to the floor and to a part of the outer wall of the nose. The membrane was about half a millimetre to a millimetre thick, and showed numerous bloody points of attachment. Further treatment for the day was to wash with a cotton swab the raw surface in the nose with 1-to-1,500 bichloride.

June 6th.—Membrane has reformed and was found to be more difficult to remove than on yesterday. Raw surface bleeds when attempt is made to pull it off. With the aid of the warm soda solution it, however, finally came away. The membrane, half a millimetre to a millimetre thick, was attached to the mucous membrane of the nostril, to that of the septum as far back as could be seen by anterior rhinoscopic examination, to the middle turbinate bone, its lower part, to the inferior turbinate, and to the floor of the nose. Surface again washed with bichloride, 1 to 1,500. Patient given iron. Told to wash the nose with soda solution.

7th.—Membrane again reformed. Treatment as yesterday.

9th.—Membranous deposit to-day is slight and chiefly around the nasal entrance. Is readily cleansed with the warm soda solution. Patient recovered without trouble. Excessive mucous discharge, however, continued from the nose, especially the left side, for some weeks.

The case is reported for several reasons. In the first place, the literature of membranous inflammations of the nasal cavities is not overabundant, and in more than one particular the case above reported allows an insight into the nature of this disease somewhat different from that usually obtained. Bosworth says: "If now a careful examination is made of the false membrane, it will be found that it is easily detached from the mucous membrane beneath it without causing hæmorrhage. This, I think, constitutes the pathognomonic symptom of a croupous exudation in this region, as distinguished from a diphtheritic." This test of the nature of an exudation upon a nasal mucous membrane has so many exceptions as to be worthless. Let us take, for example, the membrane that from time to time forms on the mucous surfaces after the application of the galvano-cautery or a strong acid. From the time of the formation of this membrane up to a certain point of its history detachment is followed by hæmorrhage more or less marked. Later on the membrane "is easily detached, without causing hæmorrhage." These irritation membranes I have never seen as thick or dense as that formed in this case. Furthermore, under the action of certain solvents these membranes can be detached without causing hæmorrhage, when simply rubbing or pulling them off would cause marked flow of blood. Thus, in this case, so firmly attached was the membrane to the surface below that pulling off even a very little piece of it was followed by the loss of about a teaspoonful of blood, whereas after the membrane had been soaked for some few minutes in a warm solution of cooking soda the whole membrane came away practically without the loss of blood. It, however, left beneath it a raw surface which would bleed under little provocation. In a case where the membrane was so thick and so extensively attached as here one would naturally think of diphtheria as the possible cause. There were, however, no constitutional symptoms to bear out this possibility. The child played about the house and yard, and, except that it complained that its nose was stopped up, seemed perfectly well. It is true that "two weeks or so" before, the child had had "amygdalitis with some white patches on its throat." The family physician had seen the case and had found in it nothing to justify fears of diphtheria, knowing as he did the child's "croupous tendency." The child was well in a few days. How long this deposit had been present in the nose I do not know, although it would seem little likely that it had existed since the time of the amygdalitis. It had been first noticed two days before I saw the case. There is one point of interest here. The mother had, because of the amount of mucous secretion, been "washing the nose out with water, using a syringe" for the purpose. It is not improbable that the force with which the water struck the septum may have been sufficient extra cause to induce a membranous inflammation in an inflamed nose. Or the water may have been dirty, and

so have conveyed to the inflamed parts the cause of this deposit.

The fact that the inflammation was unilateral lends, I think, strength to the supposition that the water was the cause of the membranous nature of the inflammation in this side; for while there was a deviation into this side posteriorly, the anterior part of this nose was more roomy than that of the other side, and hence not only could more water be easily injected into this side, but there was a greater tendency for its accumulation, there being a partial closure of the posterior nose. The nature of the membrane was firm and tough and it showed no disposition to leave its place. The lack of concomitant constitutional symptoms pointed to the local origin of this membrane. In regard to the weak solution of bicarbonate of sodium as a partial solvent of this membranous deposit, it need only be said that this simple remedy has never obtained the recognition it deserves as a cleanser of the mucous surfaces. I know of nothing that equals it as a wash whose chief object is the cleansing of the nose of secretions or deposits. In acute coryza, *e. g.*, a spray of warm bicarbonate-of-sodium solution will cause almost instantaneous cessation of the discharge. Its effects are, however, only temporary; but if the spraying be repeated a few times at intervals of half or three quarters of an hour, it is more efficacious in shortening the attack than any other remedy I know of. Nor has the value of this remedy received the attention it deserves in the treatment of the acute forms of pharyngitis, etc. The membrane was not bacteriologically examined. What such an examination would have revealed it is impossible to say. If the Klebs-Loeffler bacillus were present—and it is not improbable that such might have been the case—the absence of constitutional symptoms calls for comment. If present in its "attenuated form," it is even thus a powerfully active agent to reproduce so thick a membrane in twenty-four hours. If in its virulent form, the absence of constitutional symptoms might be due to the distance of the anterior nose from any system of lymphatic glands.

SYRUPUS ACIDI HYDRIODICI.

By W. BLAIR STEWART, A.M., M.D.,

INSTRUCTOR IN THERAPEUTICS;
LATE INSTRUCTOR IN PRACTICE IN THE MEDICO-SURGICAL COLLEGE,
PHILADELPHIA.

SINCE the introduction of the syrup of hydriodic acid into our Pharmacopœia as an official remedy much discussion has followed, both favorable and unfavorable to its use. It has been my privilege to use the syrup of hydriodic acid in a large number of cases in private practice with such uniform success that it may not be amiss to detail some of the results and conclusions reached.

Preparation.—As stated by all reliable authors, syrup of hydriodic acid is not absolutely stable, and every preparation will undergo slight changes in course of time. A reliable preparation should be perfectly clear, or of a very slightly tinted straw-color; sweet to the taste and not irritating; without acid odor; absence of iodine reaction with starch; absence of fermentation; syrupy in consistence and

palatable to the taste. Dark-brown preparations are worthless, unsatisfactory, irritating, nauseating, and dangerous, and must be condemned at once. Fermentation destroys its efficiency by liberating free iodine and hydriodic acid, which is a gas. Any preparation which has stood for a length of time exposed to the air, heat, or strong light should not be used. Small, dark bottles, hermetically sealed, are preferable to large ones, unless the syrup is used within a short time—this is especially the case in hot weather. It should not be dispensed in large quantities and is best given in its pure state (to be mixed with water when taken) rather than in combination. Combinations are liable to undergo changes more rapidly than the simple drug, and are to be avoided. There are a number of reliable preparations on the market, and, if the above-mentioned points are followed, there will be no difficulty in selecting them.

A large number of failures with syrup of hydriodic acid have been traced by the author to the use of improper preparations or to its administration where it was not indicated. This suggests the questions, What are the advantages of syrup of hydriodic acid? and What are the indications for its use?

It is palatable; does not irritate the stomach; can be given in small bulk; is not objectionable to children, and does not contain objectionable materials. Iodide of potassium makes a nauseous dose, large in bulk, and hard to administer to children. Potash also irritates the kidneys. Hydriodic acid will produce the same physiological effects as any other preparation of iodine, and will cause coryza, ptialism, skin eruptions, and anemia, if pushed in amount.

Indications.—Tertiary syphilis in all its forms; strumous diathesis and its various manifestations; rheumatism; eczema—in fact, it is to be used internally as any other iodide.

Clinical Cases.—CASE I.—A little girl, aged four years, was weak and cachectic from infancy. Six months before seeing the child it developed phlyctenular keratitis and conjunctivitis in the right eye. There was also coryza, excoriation of the upper lip, general anemia, and malnutrition. When I was called the child was in such a condition that the parents and, unfortunately, their former physician had given up all hope of saving the child's eye, or even its life. At my first visit the child was given an ointment of yellow oxide of mercury (one grain to the drachm of refined cosmoline), to be instilled into the eye twice daily. Syrup of hydriodic acid was ordered in three-drop doses three times daily, to be increased one drop every other day until ten drops were taken at a dose. A diet of meat, rich milk, eggs, and vegetables was ordered. In one week the change was marvelous. The eye was better and every symptom was improved so much that the same treatment was continued. The syrup was increased to fifteen drops three times daily. In three months the child was entirely cured. The eyesight is perfect and only a small cicatrix remains on the margin of the cornea. The coryza has entirely disappeared and the child is robust and constantly gaining in flesh. No medicine other than that mentioned was used. No amount of inquiry could elicit the least possibility of specific trouble and the case was undoubtedly one of strumous origin.

CASES II AND III.—Two babies, aged about nineteen months, in separate families, whose parents were in perfect health,

both affected alike. Typical cases of eczema capitis; coryza; general marasmus; blue, anemic skin; diarrhoea of an obstinate but subsacute character, and both children unusually small for their age. Locally the head was first thoroughly anointed with hot sweet oil, and then cleansed with green soap and hot water. A ten-per-cent. ointment of ung. hydrargyri oleat., in lanoline, was applied night and morning. Syrup of hydriodic acid was given in three-drop doses, three times daily, in water. In one week the dose was gradually increased to ten drops, and continued constantly for two months. The results in both cases were most satisfactory. Head was entirely cured; diarrhoea ceased; both gained in flesh and began to lose that blue anemic appearance. To-day, one year after my first visit, both children are perfect pictures of health, and neither child has shown the least disposition to relapse. Hydriodic acid was continued twice daily for six months in both cases.

CASE IV.—Thomas K., aged thirty-five years, Irish, tertiary syphilis ten years after inoculation. Several ulcers on buccal cavity and lips, raw gummatous growths on nates and corner of mouth, loss of hair, constipation, headache, and general debility. Mercury could not be tolerated in any form. Iodide of potassium proved so irritating and objectionable to the patient that it could not be used. Ten-drop doses of syrup of hydriodic acid were ordered in water three times daily, to be increased one drop each day until sixty drops were taken at a dose. The ulcers and gummata were treated with a powder of zinc oxide two parts, boric acid and aristol one part each. The syrup was well borne by the stomach, and improvement was so rapid that the same treatment was continued for three months, during which time he had gained twenty pounds; constipation had disappeared and every symptom was so much improved that the patient considered himself cured. He now takes the following pill three times daily, which will be continued even though all symptoms have disappeared:

R Hydrargyri protiodi..... gr. $\frac{1}{2}$;
Acidi arseniosi, { aa gr. $\frac{1}{10}$. M.
Strychnina sulphatis, {

These cases, selected from a large number of equally interesting and successful ones, will serve to illustrate the efficiency of this drug. It has served me well in chronic rheumatism in two cases. Its value in the treatment of eczema in the adult is aptly shown by another case which demanded my attention.

CASE V.—John B., aged thirty-eight years, was troubled for years with chronic eczema of the hands, arms, and legs, but has been in comparatively good health otherwise. Was ordered half a teaspoonful of syrup of hydriodic acid in water, three times daily after meals, to be increased daily until one teaspoonful was taken. Locally he was given—

R Hydrargyri oleatis..... ʒ ss.;
Olei cadini..... ʒ ss.;
Olei rose..... gtt. v;
Adipis purificat..... ʒ ss.

M. Sig.: Use locally night and morning.

Treatment continued six months, resulting in the disappearance of all symptoms. At times there is a tendency for it to recur, but a renewal of treatment causes it to disappear almost immediately.

My experience with reliable preparations of syrup of hydriodic acid leads me to the conclusion that it can be safely and efficiently used in all cases where an iodide is indicated internally, and only in my poorest families, who can not afford its use, is the iodide of potassium or ammonium substituted.

FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, AUGUST 26, 1893.

THE DIRECT TREATMENT OF FRACTURED BONES.

In his presidential address delivered at the recent annual meeting of the American Surgical Association, published in the August number of the *Annals of Surgery*, Professor Nicholas Senn, of Chicago, brought forward a practically new and, we should say, highly ingenious and efficient method of direct fixation of the fragments in the treatment of compound fractures and in that of simple fractures in which for any reason, such as non-union, it is thought best to expose the fracture by an incision and attempt direct immobilization. Really two original methods are described, each of which has its own range of usefulness. The first consists in the insertion of a tube of sterilized bone into the medullary canal of the injured bone—one end of it into one fragment and the other end into the other. This is manifestly so superior to the use of solid plugs of bone or ivory that Professor Senn is abundantly justified in proclaiming it as original. The tube is made from the shaft of a long bone of the turkey, the chicken, or the rabbit by enlarging the medullary canal by means of a small round file and then drilling numerous holes in its wall. Not only do these procedures greatly reduce the amount of foreign material that will sooner or later have to be removed by absorption—and, as the author points out, there is a limit to such absorption—but they vastly increase the surface upon which the forces of absorption are enabled to act; furthermore, this perforated tubular plug can be inserted with a minimum of disturbance of the marrow belonging to the fragments of the broken bone, and the perforations allow new blood-vessels to penetrate from the medullary cavity to the osseous shaft. The plug constitutes, in short, an absorbable intra-osseous splint that effectually prevents slipping of the fragments, while interfering as little as could be hoped for with the normal anatomical conditions.

The other method is by the use of a bone ferrule slipped over the fragments, care being taken not to disturb the periosteum more than is really necessary. "The ferrules are made," says Professor Senn, "of different sizes from fresh bone obtained from the slaughterhouse or butcher shop. For the humerus and femur of the adult the femur of an ox should be selected; for children the same bone of a smaller animal will answer the purpose. For the tibia the corresponding bone of the animal is chosen. With a sharp saw the shaft of the bone is cut transversely, the length of the sections corresponding with the desired width of the ferrule, which will vary from a quarter of an inch to an inch. With a round file the medullary canal is enlarged until the thickness of the bone does not exceed one sixth of an inch; in some instances a much thinner

ring will furnish the necessary lateral support. If the ferrule is longer than an inch it should be perforated at a number of points, in order to furnish so many avenues through which the products of tissue proliferation and the new blood-vessels can reach the tissues outside of the ferrule, and *vice versa*, and also with the intention of facilitating the absorption of bone after the fracture has become consolidated. Ferrules made of the tibia should retain the shape of the bone, in order to adapt their lumen to the treatment of fractures of the tibia. Sterilization is effected by boiling for an hour or more, after which the rings are kept immersed in sublimate alcohol (1 to 1,000) ready for use." It is thought that the ferrules should be a little too large rather than at all too small, for a large one can be wedged tight by means of pieces of asepticized bone, but there is great danger of breaking a small one in the subsequent application of the plaster-of-Paris splint, which auxiliary means of immobilization is required whichever method of direct fixation is employed. In cases of compound fracture, if the wound is of a kind not to call for drainage, it should be closed with buried sutures; in any case a fenestra should be left in the plaster splint through which the wound may be inspected and treated.

Professor Senn feels sure that these intra-osseous splints and bone ferrules are soon absorbed, and his experience in their use thus far has been highly satisfactory. He gives the details of three cases in which the ferrules were used.

Professor Senn closes his most instructive address with the following conclusions:

1. Direct fixation of the fragments is indicated in all compound fractures in which perfect retention can not be secured by simpler measures, and in the treatment of ununited fractures requiring operative interference.
2. This method is also justifiable in the treatment of certain forms of subcutaneous fractures in which reduction and retention can not be accomplished without it.
3. Free exposure of the fragments in compound fractures secures the most favorable condition for thorough disinfection.
4. Perfect reduction and direct fixation of the fragments are the most reliable prophylactic measures against delayed union, non-union, and deformity.
5. A compound fracture should be regarded in the same light as an injury of the soft tissues, and should be treated upon the same principles—viz., accurate coaptation of the different anatomical structures and perfect retention by direct means of fixation, aided by an efficient external support.
6. Bone suture and metallic, bone, and ivory nails do not furnish the necessary degree of support and immobilization in the direct treatment of fractures characterized by a strong tendency to displacement.
7. The solid intra-osseous splint of ivory or bone, as advised by Heine, Langenbeck, and Bircber, is objectionable, because it interferes with the ideal production of the intermediate callus, and its spontaneous removal is beyond the absorptive capacity of the tissues.
8. The hollow, perforated ivory or bone cylinder devised by the author answers the same mechanical purpose without the objections which have been charged against the solid cylinder.
9. The safest and most efficient means of direct fixation of oblique fractures is by a

bone ferrule, which must be applied in such a manner that it surrounds both fragments. 10. Such a circular absorbable direct splint prevents lateral and longitudinal displacement to perfection. 11. Rotation of the limb below and angularity at the seat of fracture must be prevented by a carefully applied circular plaster-of-Paris splint. 12. For fractures not requiring drainage the entire wound should be closed by buried and superficial sutures, as the bone ferrule is removed by absorption. 13. In suppurating wounds the bone ferrule should not be removed until direct fixation has become superfluous by the formation of a sufficiently firm union between the fragments. 14. The external splint should be applied in such a manner that it does not require a change throughout the entire treatment, permitting at the same time access to the wound, should this become necessary. 15. Direct fixation of a fracture combined with perfect immobilization brings the different anatomical structures of the broken bone permanently into their former normal relations, preparing the way for the early initiation and speedy consummation of an ideal process of repair and the realization of a perfect functional result. 16. Should future experience demonstrate that bone is not sufficiently absorbable, the same kind of ferrules can be made of partially decalcified bone or chromicized catgut.

AN INJUSTICE TO THE OFFICERS OF THE MARINE-HOSPITAL SERVICE.

THE announcement of the death, from yellow fever, of Assistant Surgeon J. W. Branham, of the Marine-Hospital Service, who was recently ordered from duty at this port to assume command of the quarantine service at Brunswick, Ga., where there was a slight local outbreak of that fever, adds another name to the roll of honor of officers that have died of disease incurred in the line of duty.

The officers of the Marine-Hospital Service that have died of yellow fever acquired at their stations were Assistant Surgeon Roswell Waldo, at Cairo, on October 18, 1878; Assistant Surgeon W. C. W. Glazier, at Key West, in December, [1880; and Assistant Surgeon John F. Groenevelt, at Chandeleur Island Quarantine, on June 29, 1891. To these may be added the death, in 1889, of Passed Assistant Surgeon F. M. Urquhart, whose illness was the result of exposure and overwork incident to quarantine duty.

From 1878 to 1893, inclusive, five officers have died of disease incurred in the line of duty, in a corps that does not attain a total, in the fifteen years, of a hundred officers. The mortality among the officers is greater from this cause than from all others put together. Besides these deaths, several officers on quarantine duty have been dangerously ill, but have recovered.

The reason for calling attention to the matter is a gross injustice that the United States Government does to these officers. A young physician entering the Marine-Hospital Service knows that he may be on duty at some port where yellow fever may break out, or he may be ordered to duty where it exists.

It can not be denied that he has full knowledge of the contingencies associated with holding his commission, just as the medical officer of the army or navy has that he may lose his life in warfare; but in the army or navy a pension is granted to the family of the deceased, while those dependent upon an officer who is fighting against the invasion of disease are not only bereft of their relative but deprived of all support. In most of the instances that are herein specified dependent relatives have been left to provide for themselves as best they could.

It is not credible that the American people would be willing to perpetuate such an injustice if the matter were presented for their consideration. Surely in case of death under such circumstances a pension is as justly due to the family of the deceased officer as it is to the family of one that loses his life in military warfare.

It is understood that a bill will be prepared and introduced into Congress at an early date, providing for a proper pension to the dependent relatives of a medical officer that has lost his life in the noblest way it is possible for man to die—in the discharge of duty.

THE CHOLERA AT NEW YORK QUARANTINE.

THE admirable system, authorized by the recent quarantine law, of stationing sanitary inspectors of this Government at foreign ports has demonstrated its advantages during the present summer. Reference has been made to the fact that Surgeon Fairfax Irwin telegraphed from Marseilles on the 27th of May that cholera existed in that city, although the authorities then and for some time subsequently denied the fact. On July 19th Assistant Surgeon G. B. Young telegraphed from Naples that there had been four cases of cholera in that city on the 17th of that month. This report was at once denied by the Italian authorities. The information, however, served a good purpose, for on August 4th the steamship Karamania, that had cleared from Naples on July 15th having 471 passengers, arrived at the New York quarantine station with a history of the death of one passenger from congestion of the lungs on the second day out, and of the death of two passengers, on August 2d and 3d respectively, of diarrhoea and vomiting.

Although the ship had sailed two days previous to the known occurrence of cholera in Naples, Health Officer Jenkins decided to detain her at the lower quarantine for observation. The wisdom of his action was shown by the removal of a passenger suffering from cholera, as demonstrated by bacteriological examination, to the Swinburne Island hospital on August 5th. On August 8th another cholera patient was taken from the observation barracks on Hoffman Island, and he died on the evening of the 9th. On the latter evening two more patients were transferred; on the 10th, five patients; on the 11th, eight patients; on the 12th, one patient; and on the 13th, two patients. There was a total of twenty cholera patients, and three of these died. The passengers under observation were discharged on August 22d, nine days after the last cholera case occurred.

Health Officer Jenkins is to be congratulated upon the promptness and efficiency with which he handled this vessel and its passengers, and the public press is to be commended for the manner in which it avoided alarming head-lines calculated to intimidate many people and produce a senseless stamped effect such as was witnessed last year.

MINOR PARAGRAPHS.

THE INSURANCE VALUES OF HANDS AND FINGERS.

The *Medical News* for July 22d has an article treating of the statistics given by some companies relative to accident insurance involving the upper extremity. Conservative surgeons have frequent opportunities to modify the probable damages after injury to the hand, as well as to estimate the chances of adding to the ill results by trying to save overmuch. According to a scale of values furnished by the miners' unions and miners' accident insurance companies of Germany, the loss of both hands is valued at a hundred per cent., or the whole ability of a man to earn a living. Loss of the right hand depreciates the working value seventy to eighty per cent., while that of the left hand rates at sixty to seventy per cent. of the earnings of both hands. The thumb is reckoned to be worth twenty to thirty per cent. of those earnings. The forefinger of the right hand is valued at fourteen to eighteen per cent., that of the left hand at from eight to thirteen per cent. The middle finger is rated four per cent. under the first finger. The third finger has a value of only seven to nine per cent., the little finger rating two per cent. higher. The differences in percentages affecting any given finger are governed by the vocation of the injured person; thus it is manifest that the forefinger and the little finger are either of them much more valuable to the literary man or bookkeeper than to the man who works with the pick and shovel. To the latter the middle and third fingers will be especially advantageous, because they relate to the grip which the laborer should have upon his heavy tools.

THE LEGAL STATUS OF THE INSPECTION OF STATE QUARANTINES BY THE UNITED STATES.

The *Abstract of Sanitary Reports* for August 11th contains the opinion of the Department of Justice as to the right of the national Government, under the quarantine act approved February 15, 1893, to inspect, at such times as may be necessary, a State or municipal quarantine of the United States. It is held that the national quarantine system provided for by Congress has necessarily inspective and supervisory powers over the sanitary authorities of the State or municipality, because whenever a power is given by a statute everything necessary to make it effectual or requisite to attain the end is implied; and when a statute gives a right to impose a duty it also confers by implication the power necessary to make the right available or to discharge the duty. Therefore the Government may authorize the inspection of the condition of State or local quarantines by proper officers connected with the Marine-Hospital Service.

THE IMPURE LEMONADE OF COMMERCE.

The *Pharmacological Record* for August points out the injurious nature of some of the compounds sold as "lemonade." Lead was found in appreciable quantities in six of the seven specimens examined. The proportion of lead in some of them was as high as four and six parts in a million—a fact not to be

accounted for by the amount of that metal that very constantly contaminates commercial citric acid. In three instances citric acid was absent, its place being taken by tartaric acid. In five cases there was no cane sugar, its place being taken by grape sugar and saccharine. Phosphoric acid was found in three out of seven examples. This acid is sometimes known as "liquid citric acid" to the manufacturers of table waters; also a combination is employed under the name of "citro-phosphoric acid," which is a cloak to cover a multitude of impurities. However valuable phosphoric acid may be as a medicinal agent, it is decidedly undesirable in a beverage for daily consumption. Helbing and Passmore, whose report it is that occupies the *Record* on this subject, found one of the seven that is practically a standard and safe preparation; the water was pure, there was no acid save citric only, and there was no sweetening agent save cane sugar only.

SIR BENJAMIN RICHARDSON.

DR. BENJAMIN WARD RICHARDSON, a London physician very well known in this country, received knighthood from Queen Victoria on the occasion of her last birthday. One of the best of his literary productions is *Hygieia: a City of Health*. When it was published, in 1875, it soon became popular and was reprinted and translated to an extent seldom seen in respect of a sanitary essay. Dr. Richardson's researches in regard to peroxide of hydrogen, nitrite of amyl, and bichloride of methylene were original and permanently valuable. He has edited, during recent years, the *Aeolepiad*, a personal organ having reference chiefly to clinical observations. Dr. Richardson has been a preeminently useful man in his day and generation.

SENSORY DISTURBANCES IN DIABETES.

DR. P. VERGELY contributes a paper to the *Gazette hebdomadaire de médecine et de chirurgie* for August 12th in which he concludes that disorders of the peripheral sensory nerves frequently occur in diabetes, disorders of pain and temperature sense predominating. In a certain number of diabetics thermodysaesthesia, thermo-hypaesthesia, and thermo-anesthesia are encountered, the first disorder appearing in patients that have no other sensory disorder. In one instance a diabetic was analgesic and completely thermo-anesthetic, and presented to a certain extent the sensory dissociation observed in myelosingosis.

NEWSPAPER MEDICINE.

SOME of our lay contemporaries have, on occasions, quite an unsuccessful struggle with the orthography of technical medical terms, and the struggle becomes amusing when its results appear in the columns of a paper noteworthy for its general freedom from errors. In a recent issue of one of our city evening papers the Quarantine Report, as published, made it appear that a certain young woman had died of "pneumonia and pasenchimutars [*sic*] nephritis." Was the medical editor on vacation, or had the office cat been toying with the type?

ITEMS, ETC.

Recent Medical Legislation in Massachusetts.—Speaking of the legislation of 1893, in so far as it bears upon medical matters, the *Boston Medical and Surgical Journal* for August 17th says:

"The law providing for the registration of deaths by physicians, in connection with the obtaining of a burial permit by undertakers, has been amended so that in cases of still-born children and those dying immediately after delivery the same form is required as in other

deaths, and a penalty is provided for making false statements. The law now reads as follows: 'A physician who has attended a person during his last illness shall, when requested, forthwith furnish for registration a certificate stating, to the best of his knowledge and belief, the name of the deceased, his age, the disease of which he died, the duration of his last sickness, and the date of his decease; and a physician who has attended at a birth of a child dying immediately thereafter, or at the birth of a still-born child, shall, when requested, forthwith furnish for registration a certificate stating, to the best of his knowledge and belief, the fact that such a child died after birth, or was born dead. If a physician neglects or refuses to make a certificate as aforesaid, or makes a false statement therein, he shall be punished by a fine not exceeding fifty dollars.'

'A law regulating so-called sweat-shops provides that all places used as dwellings in which garments are made intended for sale shall be licensed and superintended by the police, or special inspectors, and that, in cases of danger from infectious diseases or vermin, the State Board of Health shall take charge and control. Also that all garments made in such places shall bear tags, with the name of the State and town in which they were made.'

'Local boards of health are required to notify the State Board of the existence in their districts of any disease dangerous to the public health.'

'A law to abate the smoke nuisance in Boston provides that where bituminous coal is used to make steam in boilers, at least seventy-five per cent. of the smoke must be consumed or prevented from entering the atmosphere.'

'The State Board of Health is directed to investigate the question of a water supply for Boston and neighboring towns, and to report in January, 1895.'

'The same board with the park commissioners shall investigate the sanitary condition of the Charles River Basin up to the Waltham line.'

'The members of the State Board of Cattle Commissioners are given power to enforce rules for the prevention of disease among animals.'

'Hereafter plumbers must be licensed, and must pass an examination. The examining boards consist of the chairman of the local board of health and the inspector of buildings. It will be no longer possible for any ignoramus to practice plumbing, but the practice of medicine is still unrestricted.'

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending August 22, 1893:

DISEASES.	Week ending Aug. 15.		Week ending Aug. 22.	
	Cases.	Deaths.	Cases.	Deaths.
Typhus	1	0	0	0
Typhoid fever.....	30	3	30	4
Scarlet fever.....	43	1	34	4
Cerebro-spinal meningitis. . .	0	0	3	0
Measles.....	124	4	102	7
Diphtheria.....	100	30	104	29
Small-pox.....	1	1	1	1

The Board of Medical Examiners of Montana.—The president, Dr. Charles K. Cole, writes to us as follows: 'At the recent meeting of the National Conference of State Medical Examining and Licensing Boards, held at Milwaukee, June 7, 1893, it was the express desire of the members present that during the present year all State boards should be enrolled as members of the conference, and that the next meeting be made one of more than ordinary interest and profit to us in our work of elevating the standard of medical education. It is also desirable that there be established closer relations between the various boards so that there may be an interchange of ideas and an active co-operation in all that pertains to higher medical education. In order to bring this about there is much to be done, and immediate action should be taken. As secretary and treasurer of the conference, I earnestly request your aid and assistance in accomplishing the desired end. I

therefore ask that the members of your board, if not already enrolled, become members at once by sending in their applications and first annual fee of \$2. That the records of the conference may be made complete, kindly send me as soon as possible copies of your medical-practice acts, reports (as complete files as convenient), circulars, or other documents that will aid in tabulating and recording the work of the various boards. These reports, etc., will be carefully kept on file for future use and become the foundation of a history of State medical examining and licensing boards and the work done. From time to time you will be communicated with upon matters of mutual interest, and I trust you will, in turn, keep this office informed of all matters of importance by communications, reports, circulars, etc. We have a most important duty to perform, and it will succeed if all will enter into it with zeal and determination. The next meeting will be held in San Francisco during the meeting of the American Medical Association.'

The Postponement of the International Medical Congress.—The *Lancet's* Rome correspondent, under date of August 3d, says: 'This announcement (of the postponement) has fallen on the Italian public, professional and non-professional, like a bombshell, because when (as duly reported in the columns of the *Lancet*) a 'pilot-balloon' was started to similar effect last spring it was, after going the round of the European press, contradicted on authority by the Secretary General, Dr. E. Maragliano. 'Certain political journals' were, in that official contradiction, credited with having launched the 'ballon d'essai' in question, and once more the world relapsed into the belief that, in Dr. Maragliano's words, 'the date of inauguration was definitively fixed for September 24th.' Even this morning (the 3d inst.) the leading journal of Rome, the *Opinione liberale*, was still without official intimation of the 'ordine del giorno' given above and declined to believe an early anticipation of it published in a contemporary. 'On inquiry,' said the *Opinione liberale*, 'at the Direzione generale di sanità we were assured that "finora" (that is, up to the eve of the 3d inst.) no decision had been taken, but that certainly, if "le malattie infettive" (infectious diseases) were to continue in Russia, in France, and in other countries, the International Medical Congress would be postponed.' In its issue of to-day the *Opinione liberale* informed its readers that, 'nevertheless'—that is, even if, the congress were postponed—the Exposition would still be held, and then it proceeded to give a glowing account of the labors *ad hoc* of the superintendent, Professor Pagliani, and of his coadjutors, Professor Bentivegna, Dr. Sambon, and the engineer, Signor Borlenda; but later, in its 'ultime notizia,' the *Opinione liberale* had to admit the truth of what its contemporary had foreshadowed and to announce the postponement till April next of congress and exposition alike. As I have indicated, this change in the time of meeting of such an ecumenical gathering has had a startling effect and has already disturbed the arrangements of a number of allied congresses which had fixed their dates with reference to this supreme one. The International Congress of Otolaryngology, for example, the fifth of the series, which was to have attracted the medical world on its way to Rome in September next and to have been held in Florence just before its great sister met in the capital, has also had to postpone its meeting. As to the disturbance of the long-adjusted arrangements of representatives from the New World and the Antipodes, I can but hope that the telegraphic agencies will have forewarned them in time of the futility of starting for Rome this year. The inference, however, seems inevitable that it was only in the most imperative necessity—in which it found itself, as stated, in agreement with the other European committees—that the Comitato Ejecutivo could have ventured at the eleventh hour to countermand an undertaking for which such elaborate preparations were in progress and in which so many distinguished consultants and teachers, whose time is so precious, had pledged themselves to take part.'

The *British Medical Journal* proposes our approaching Pan-American Medical Congress as a substitute for the one that has been postponed. It says editorially:

'The postponement of the International Medical Congress at Rome will come as a great disappointment to a great number of British members of the medical profession, who proposed to combine the scientific interest of a congress with the amenities of a holiday in Rome, and the holiday arrangements of many medical

men are thus left open for rearrangement. It will probably have suggested itself to many that this will afford an opportunity for substituting a similar holiday of mixed scientific interest and recreation by taking the opportunity thus afforded of visiting the Chicago World's Fair, and of combining with that unique experience a visit to the Pan-American Medical Congress at Washington, which will be held on September 5th. All British medical men will receive a warm welcome at this International Congress of Medicine, toward the funds of which for purposes of hospitality and organization the American Government have largely contributed. The secretary of the Pan-American Congress is Dr. Read, Cincinnati, Ohio, who will be happy to afford every information and facility to European visitors. The Cunard steamer *Campania*, the fastest boat on the ocean, which starts from Liverpool on August 19th, will probably land her passengers in New York on the night of the 25th, and the *Umbria*, which sails on Saturday, the 26th, will probably land them on the morning of September 2d. Passengers sailing by either ship would arrive in good time for the congress. The visit to the World's Fair at Chicago may be made either before or after the congress, according as may be most convenient. If a considerable number of medical men desire to combine for the journey it is probable that some special arrangements might be made for their convenience by the Cunard Steamship Company."

The City Board of Health's Bacteriological Work in Diphtheria.

The following is the report of the chief inspector in pathology, bacteriology, and disinfection, dated August 15th and addressed to the president, the Hon. Charles G. Wilson:

Some months ago the Health Board determined to increase the facilities at its command for the diagnosis and treatment of diphtheria by perfecting arrangements for the bacteriological examination of all cases of this disease that came directly under its care, and further determined to proffer to all physicians in this city the aid of a skilled bacteriologist in the diagnosis of all suspected cases of this disease. This course, it was thought, would not only bring the work of the board in its relations with diphtheria abreast of the most recent discoveries, and would be of the greatest practical value, but would also be gladly welcomed by the physicians of the city, as it placed at their command such skilled assistance in the diagnosis of this disease as they could not otherwise secure.

The step constituted a very important advance, quite in harmony with the previous action of the board in dealing with contagious diseases, and was suggested by recent bacteriological investigation conducted in the hospitals for contagious diseases both in this city and in Europe. These investigations have shown that a considerable proportion of the pseudo-membranous and exudative inflammations of the throat and upper air passages, commonly considered as diphtheria and having the anatomical appearances found in diphtheria, are not true diphtheria, but are of a far less serious nature. These latter cases may be called false diphtheria. The importance of the separation of the cases of true from those of false diphtheria is due to the fact that, while in true diphtheria the mortality is very high and the danger of transmission to others is great, in false diphtheria the mortality is very low and the danger of infection slight.

The distinction between true and false diphtheria, though often difficult or impossible without the aid of a bacteriological examination, can in this way be made within a few hours.

Early in May, therefore, the board appointed Dr. William Hallock Park inspector and bacteriological diagnostician of diphtheria. Dr. Park had peculiar qualifications for the discharge of the duties of this position, derived from a long study and large experience in this particular line of bacteriological work.

Since May 6th the department has been prepared to make use of bacteriological cultures in all cases of suspected diphtheria occurring in the city, and has announced to physicians that it would make such examinations in all cases reported to the department unless for any reason the physician in attendance preferred not to have them made. Up to this time, however, no examinations have been made without the specific consent or request of the physician in charge, excepting in cases about to be removed to the Willard Parker Hospital.

As many physicians were not familiar with the work or its results, it has required the expenditure of no little time and labor to disseminate the necessary knowledge regarding it. The number of cases examined as compared with the whole number reported has been comparatively small, but has been gradually increasing, as the appended table will show. From this date a very large proportion of all cases will no doubt be examined.

The new work has been received by the medical profession with almost universal and enthusiastic approval. Arrangements have been made with a number of druggists scattered throughout the city to keep a supply of the culture tubes, as furnished by the department, for inoculations, so that they will be within convenient reach of physicians when they desire to themselves make the inoculations. These tubes are furnished without charge. After being inoculated they are returned to the station from which they were obtained, and are collected each evening by the department collector. A report of the examination is forwarded the following morning to the physician. When the physicians request it, the inspectors of the department make the inoculations.

Of the 431 cases thus far examined, about one third have proved to be false diphtheria. This is a much smaller proportion than exists during the winter and spring months, when, as experience has shown, fully half of the cases admitted to the Willard Parker Hospital are false diphtheria, and probably of those reported to the department a still larger percentage are of this form. Cases which prove to be false diphtheria will not receive further detailed attention from the health department. Cases, on the other hand, which prove to be true diphtheria will be subjected to the usual rules and regulations covering contagious diseases.

It seems hardly necessary to refer to the great influence that these examinations will have in giving precision to the work of the department and in reducing the labor required in dealing with this disease. It is the further purpose of the department to enlarge the scope of the work to include a careful study of the best measures to be employed in the treatment, disinfection, and prevention, of diphtheria.

A large number of inquiries have been received from sanitary officers in other cities concerning the methods employed in this work, and already there are indications that the initiative step taken by the New York City Health Department will be followed by other cities both in this country and in Europe.

I have the honor to present the following detailed report of the cases examined each week since May 6th, with the results of these examinations:

Report of the Number of Bacterial Cultures obtained from Cases of Suspected Diphtheria since May 6, 1893.

WEEK.	Number of cultures obtained and examined of suspected diphtheria.	True diphtheria.	False diphtheria.

The American Social Science Association.—The Education Department of the American Social Science Association meets in Saratoga on September 5th and 6th. Mr. Hamilton W. Mabie will make the open-

ing address. This will be followed by Mr. Edward Fisher's paper on The Seamy Side of the Kindergarten. Dr. G. Stanley will speak on American Colleges and their Work. Dr. Louise Fiske Bryson will read a paper on The Education of Epileptics. Dr. Frederick Peterson will present a report on Recent Progress in Medicine and Surgery. Dr. Mary T. Bissell has promised a paper on Athletics for City Girls; and there will be a discussion of hygiene and sanitation connected with school life.

Change of Address.—Dr. C. N. Hammond, from Bentley Creek, Pa., to Angelica, N. Y.

The Death of Dr. Norris M. Carter, of Brooklyn, occurred somewhat suddenly on the 11th inst. The cause of his death is reported as neuralgia of the heart subsequent to heart trouble of long standing. He was born near Belfast, Ireland, fifty-two years ago. While yet a youth he came to America, and prepared himself for his profession at Albany. He was graduated in 1859 at the medical school at that place. During the war he served as surgeon of volunteers. His career in Brooklyn was exceptionally successful.

The Death of Dr. William S. Hurd, of Paterson, N. J., on the 18th inst., removes a well-known practitioner. He was a native of Fishkill Landing, and in his forty-seventh year at the time of his death. He was an alumnus of the Medical Department of the University of the City of New York of the class of 1877. He had been city physician and coroner.

The Death of Professor J. M. Charcot, the great neurologist of Paris, is reported by cable to have occurred at Morvan on the 15th inst. Charcot was born in Paris in 1825.

Army Intelligence.—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from August 6 to August 19, 1893:*

GLENNAN, JAMES D., First Lieutenant and Assistant Surgeon, is granted leave of absence for twenty days, to take effect upon the conclusion of his examination for promotion.

FLAGG, CHARLES E. B., First Lieutenant and Assistant Surgeon, will proceed to the Yosemite National Park, California, for duty with Troop I, Fourth Cavalry, relieving WOOD, LEONARD, Captain and Assistant Surgeon. Upon being thus relieved, Captain Wood will return to his station, the Presidio of San Francisco, California.

HARRIS, HENRY S. T., Captain and Assistant Surgeon, Fort Keogh, Montana, is granted leave of absence for one month, to take effect about August 16, 1893.

LAUDERDALE, J. V., Major and Surgeon, is hereby granted leave of absence for one month, to commence about September 5, 1893.

ADAIR, GEORGE W., Major and Surgeon, is granted leave of absence for three months, to take effect on or about September 4, 1893.

KEFFER, FRANK R., First Lieutenant and Assistant Surgeon, is granted leave of absence for one month and fifteen days, to take effect when his services can be spared.

WYETH, MARLBOROUGH C., Captain and Assistant Surgeon. By direction of the Acting Secretary of War, the extension of leave of absence, granted on account of sickness, is still further extended two months on account of sickness.

TAYLOR, MARCUS E., Captain and Assistant Surgeon, having been found incapacitated for active service by an Army Retiring Board, will proceed to his home and report thence by letter to the Adjutant General of the Army.

BRADELEY, ALFRED E., First Lieutenant and Assistant Surgeon, is granted leave of absence for one month.

SWIFT, EUGENE L., Captain and Assistant Surgeon, is granted leave of absence for one month, to take effect upon the return from detached service of FISHER, HENRY C., First Lieutenant and Assistant Surgeon.

WOOD, M. W., Captain and Assistant Surgeon, is granted leave of absence for one month, to commence about September 1, 1893.

TILTON, HENRY R., Major and Surgeon, is granted two months' leave of absence when relieved from duty at Fort Wayne, Michigan.

JANEWAY, JOHN H., Lieutenant Colonel and Deputy Surgeon General.

By direction of the President, his retirement from active service this date, by operation of law, under the provisions of the Act of Congress approved June 30, 1882, is announced.

McVAT, HARLAN E., First Lieutenant and Assistant Surgeon, San Carlos, A. T., is granted leave of absence for one month, to take effect when relieved by another medical officer, with permission to apply for an extension of fifteen days.

Naval Intelligence.—*Official List of Changes in the Medical Corps of the United States Navy for the week ending August 19, 1893:*

MOORE, A. M., Surgeon, and RUSH, C. W., Passed Assistant Surgeon. Placed on the retired list.

KENNEDY, R. M., Assistant Surgeon. Promoted to Passed Assistant Surgeon.

CLARK, J. H., Medical Director, WHITE, C. H., Medical Inspector, and NEILSON, J. L., Surgeon. Ordered as members of the Examining Board.

GATES, M. F., Passed Assistant Surgeon. Detached from the Naval Hospital, Portsmouth, N. H., and detailed as Recorder of the Naval Examining Board, September 1st.

WENTWORTH, A. R., Passed Assistant Surgeon. Ordered to the Naval Hospital, Portsmouth, N. H.

GORGAS, A. C., Medical Director, SIEGFRIED, C. A., Surgeon, and BEYER, H. G., Passed Assistant Surgeon. Ordered as delegates to the Pan-American Medical Congress.

MACKIE, B. S., Surgeon, and HENNEBERGER, L. G., Surgeon. Ordered to the Naval Academy to examine applicants for admission.

Society Meetings for the Coming Week:

MONDAY, September 4th: Morrisania Medical Society (private); Brooklyn Anatomical and Surgical Society (private); Utica Medical Library Association; Corning, N. Y., Academy of Medicine; St. Albans, Vt., Medical Association; Providence, R. I., Medical Association; Hartford, Conn., Medical Society.

TUESDAY, September 5th: Pan-American Medical Congress (first day—Washington); American Dermatological Association (first day—Milwaukee); Elmira Academy of Medicine; Buffalo Medical and Surgical Association; Ogdensburg Medical Association; Hudson, N. J., County Medical Society (Jersey City); Androscoggin, Me., County Medical Association (Lewiston); Baltimore Academy of Medicine.

WEDNESDAY, September 6th: Pan-American Medical Congress (second day); American Dermatological Association (second day); Harlem Medical Association of the City of New York; Medical Microscopical Society of Brooklyn; Medical Society of the County of Richmond (Stapleton); Bridgeport, Conn., Medical Association.

THURSDAY, September 7th: Pan-American Medical Congress (third day); American Dermatological Association (third day); New York Academy of Medicine; Brooklyn Surgical Society; Society of Physicians of the Village of Canandaigua; Obstetrical Society of Philadelphia.

FRIDAY, September 8th: Pan-American Medical Congress (fourth day); Yorkville Medical Association (private); German Medical Society of Brooklyn; Medical Society of the Town of Saugerties.

Letters to the Editor.

THE PRESERVATION OF RUBBER CATHETERS.

3 MARLBOROUGH STREET, BOSTON, August 7, 1893.

To the Editor of the New York Medical Journal:

SIR: In your issue of July 22, 1893, Dr. J. W. S. Gouley, in his interesting Notes on American Catheters and Bougies, mentions the injury done to rubber catheters by fat of all kinds.

I have found by experiment that, for some reason, castor oil

does not injure these catheters as other fats and oils do. For a time I advised the use of it to my patients, where economy was an object, and they found that they could use a catheter a very long time under its use. I could not, however, render it antiseptic without employing some agent which was more or less irritating to the urethra. I have, therefore, lately used only the vaseline which comes in collapsible tubes, and which is thus easily kept clean and is readily transported; and patients find that, if they wash the catheter very carefully with soap after each use, the swelling of the catheter is so slow to appear that the expense of keeping themselves supplied is a trifling matter.

A. T. CABOT, M. D.

Book Notices.

On Chorea or St. Vitus's Dance in Children. By OCTAVIUS STURGES, M. D., F. R. C. P., Senior Physician to the Hospital for Sick Children, and to the Westminster Hospital. Second Edition, revised and partly rewritten. London: John Bale & Sons, 1893. Pp. xi-188.

WHEN the first edition of this little work appeared, in 1882, it was considered one of the most valuable monographs on the subject that had been published. In this second edition the author has given the work a general revision. He has materially amplified the section on the symptoms and the diagnosis. In the chapter on heart symptoms he has modified his former conclusions, and now states that papilliform endocarditis affecting the mitral valve is the cardinal anatomical feature in chorea, wholly apart from rheumatic endocarditis, though he believes that the heart symptoms of chorea are best explained upon the hypothesis of some pathological kinship between it and rheumatism.

There is a brief chapter on chorea as observed in school children, with simple directions for its early diagnosis. The author has also modified his earlier views regarding the relation of chorea and rheumatism, both of which he believes to be members of a pathological group that has arthritis for a common factor, though further investigation is necessary to determine what, in the last analysis, is the underlying source of all these diseases. He characterizes as feebleness of purpose that tendency to appeal to one remedy after another that is so often considered an indication of fertility of resource, and considers that moral treatment in all its phases is of the greatest use. The volume is one that will give the reader a great deal of useful information.

History of the Life of D. Hayes Agnew, M. D., LL. D. By J. HOWE ADAMS, M. D. Philadelphia and London: The F. A. Davis Company, 1892. Pp. vii-376. [Price, \$2.50.]

DR. HOWE ADAMS has performed a labor of love and done it well in this biography of his ideal physician. To those who did not know Dr. Agnew it might seem a fulsome work, but to those who have sat at his feet and known him well the encomiums fall far short of his merits, and, in the face of his personal character, seem hollow and vain. No one feels this more than Dr. Adams. Dr. Agnew's life was great in its simplicity, sweet charity, and professional integrity, yet not abounding in crises and public triumphs. It was a life to know and be a part of rather than to write about. He was purely the architect of his own fortune, and this biography of him will lend encouragement to every man of energy, industry, and honesty of purpose.

Atlas of Electric Cystoscopy. By Dr. EMIL BURCKHARDT, late Assistant Surgeon to the Surgical Clinic of the University of Bale, and E. HURRY FENWICK, F. R. C. S. Eng., Surgeon to the London Hospital, etc. With Thirty-four Colored Plates, embracing Eighty-three Figures. London: J. & A. Churchill, 1893. Pp. 70. [Price, 21 shillings.]

THIS work is really a revision of the German edition of Burckhardt's work on electric cystoscopy. It is simply an atlas, containing thirty-four colored plates with eighty-three excellent delineations of the normal and pathological appearances of the bladder. There is no text whatever except what is necessary to explain the plates. The work would have been rendered much more valuable by inserting into it a review of electro-cystoscopy and a description of its technique.

BOOKS, ETC., RECEIVED.

A Chapter on Cholera for Lay Readers. History, Symptoms, Prevention, and Treatment of the Disease. By Walter Vought, Ph. B., M. D., New York. Illustrated. Philadelphia and London: The F. A. Davis Company, 1893. Pp. vii-107.

Reactions. A Selection of Organic Chemical Preparations Important to Pharmacy in regard to their Behavior to Commonly-used Reagents. By F. A. Flückiger, Ph. D., M. D. Fourteenth Report of the State Board of Health of Wisconsin. 1891-1892.

Miscellany.

The Use of Disinfectants in the Army.—In a circular dated August 9th, Surgeon-General Sternberg says:

'Requisitions received from time to time indicate that certain medical officers of the army are not well informed with reference to the use of disinfectants.

"It may be that the meaning of A. R. 1656 and of paragraph 36 of the Supply Table has been misunderstood.

"A. R. 1656. 'Carbolic acid, chloride of lime, sulphate of iron, corrosive chloride of mercury, solution of chlorinated soda, and other articles required as antiseptics or disinfectants in hospitals and for general use at military posts will be issued by the Medical Department upon the requisition of the medical officer.'

"Standard Supply Table, paragraph 36. 'Disinfectants for general post sanitation will be issued by the Medical Department upon the annual requisition.'

"The mistaken idea that disinfectants are required 'for general post sanitation' in the absence of any infectious material to be destroyed seems to be very common among officers and non-commissioned officers of the army, and should not receive support from officers of the Medical Department.

"The definition of a disinfectant adopted by the Committee on Disinfectants of the American Public Health Association in 1885 has now been generally accepted by well-informed sanitarians. This is as follows:

"'The object of disinfection is to prevent the extension of infectious diseases by destroying the specific infectious material which gives rise to them. This is accomplished by the use of disinfectants.

"'There can be no partial disinfection of such material; either its infecting power is destroyed, or it is not. In the latter case there is a failure to disinfect. *Nor can there be any disinfection in the absence of infectious material.*

"'Antiseptic agents also exercise a restraining influence upon the development of disease germs, and their use during epidemics is to be recommended when masses of organic material in the vicinity of human habitations can not be completely destroyed, or removed, or disinfected.'

"At the conclusion of the Lomb prize essay, published by the American Public Health Association in 1885, the following propositions are formulated:

"'Disinfection consists in extinguishing the spark, killing the germ, which may light up an epidemic in the presence of a supply of combustible material—filth.

"'The object of general sanitary police is to remove this combustible material out of the way, so that no harm may result even if the spark be introduced.

"'Antiseptics and deodorants are useful when it is impracticable to remove offensive organic material from the vicinity of human habitations, but they are a poor substitute for cleanliness.'

"Chloride of lime, carbolic acid, and mercuric chloride are issued by the Medical Department for use as disinfectants, properly so called. A solution containing four per cent. of good chloride of lime, or five per cent. of carbolic acid, is suitable for disinfecting the excreta of patients with cholera or typhoid fever, or the sputa of patients suffering from diphtheria, scarlet fever, or tuberculosis. The floors, furniture, etc., in rooms occupied by patients suffering from an infectious disease may be washed with a two-per-cent. solution of carbolic acid, or with a solution of mercuric chloride of 1 to 1,000. Soiled bed linen, underclothing, etc., used by such patients should be immersed in one of the above-mentioned solutions before it is sent to the laundry. *But, in the absence of any infectious disease, these disinfecting agents are not required, and their expenditure for purposes of general post sanitation is not authorized.*

"Sulphate of iron and other cheap antiseptics and deodorants may be used when necessary. But the necessity for their use is a reach upon the sanitary police of a post and should only be required under exceptional circumstances.

"The alvine discharges of healthy persons do not require disinfection, and when properly disposed of do not require treatment with any chemical agent whatever. If water-closets or earth-closets are offensive, this is due to faulty construction, to insufficient supply of water or of dry earth, or to neglect of ordinary cleanliness. The attempt to remedy such defects by the systematic use of antiseptics is expensive and unsatisfactory in its results.

"The same is true of foul drains, bad-smelling urinals, accumulations of garbage, etc. The proper remedy for such conditions is cleanliness and strict sanitary police.

"When accumulations of organic material undergoing decomposition can not be removed or buried, they may be treated with an antiseptic solution or with freshly burned quicklime. Quicklime is also a valuable disinfectant and may be substituted for the more expensive chloride of lime for disinfection of typhoid and cholera excreta, etc. For this purpose freshly prepared 'milk of lime' should be used, containing about one part by weight of hydrate of lime to eight of water.

"During the prevalence of an epidemic, or when there is reason to believe that infectious material has been introduced from any source, latrines and cesspools may be treated with milk of lime in the proportion of five parts to one hundred parts of the contents of the vault, and the daily addition of ten parts for one hundred parts of daily increment of faeces.

"While the faeces of healthy individuals in privy vaults or on the surface of the soil are innocuous, it is well known that epidemics of cholera, typhoid fever, and camp diarrhoea are usually due to the contamination of drinking-water or food by micro-organisms contained in the excreta of persons suffering from these diseases. This may occur as the result of direct contamination of the water supply, and probably also by the transfer of infectious material to the surface of meats, milk, and other articles of food by flies which have recently been in contact with infectious excreta. This source of infection has not heretofore received proper consideration, and the probability of its occurring when the faeces of patients suffering from the diseases mentioned are deposited upon the surface of the ground, or in open privy vaults, calls for extreme care, especially during times of actual or threatened epidemic. In camp, where it is necessary to use open pits as latrines, dry earth, quicklime, or wood ashes should be frequently thrown upon the surface of faecal accumulations.

"All known disease germs are destroyed by the temperature of boiling water, maintained for a few minutes. This being the case, the destruction of articles of clothing which can be subjected to the action of boiling water or of live steam without material injury is unjustifiable. *Exposure to steam under considerable pressure, or to superheated steam, which requires a specially constructed steam chamber, is an unnecessary exaction, free exposure to flowing steam for one hour being sufficient to secure disinfection.* But this applies only to articles which can be freely exposed in a steam chamber, and not to mattresses, pillows, bundles of clothing, etc. As a rule, immersion in boiling water for half an hour will be the most convenient and most economical method for disinfecting articles of clothing, bed linen, blankets, etc.

"When hair mattresses and pillows require disinfection, it will be necessary to open them up, either before or after immersing them in boiling water or in a disinfecting solution, in order that the hair may subsequently be thoroughly dried. When this is done, the fact will be reported to the medical director of the department, and instructions will be given as to the disposition of the material.

"When of little value, or in the absence of proper facilities for disinfection, mattresses, pillows, and clothing may be destroyed in compliance with A. R. 1625; but the destruction of articles which can be disinfected without material injury by immersion in boiling water or a disinfecting solution is not authorized."

The Chinaman as a Surgical Patient.—An interesting article on Surgery in China is running through current issues of the *China Medical Missionary Journal*. It is contributed by Dr. John C. Thomson, of Hong Kong. From the installment that appeared in the June number of the journal mentioned we extract the following:

"The Chinaman's fortitude under the surgeon's knife has been sub-

ject of remark ever since the surgeons of the Honorable East India Company first began to relieve surgical conditions with which at their stations in China they were brought into contact, and continues to excite admiration now that medical missions are carrying Western surgery into many regions of the Chinese empire. The trait is of course less noticeable now than in the days anterior to the age of chloroform, but even now it is frequently put to the test in circumstances where surgeons in isolated situations are compelled to undertake operations unaided, or where otherwise the exhibition of chloroform is contraindicated, and in the minor operations of surgery. When so tested, the Chinaman will endure without flinching a degree of pain that to the more highly developed nervous system of the Westerner would be well-nigh impossible. Most of the numerous entropion operations in the Alice Memorial Hospital, for example, are performed without the use of any anæsthetic whatever, and one usually sees the minute manipulations involved endured throughout without the quiver of a single muscle, on the part of women as well as men.

"To the Chinaman, indeed, with his lack of education to the knife, the thought of cutting is repellent in the extreme, and I have many a time seen a stalwart man burst into tears at the bare proposal of incision of an abscess, but, once his mind is made up to operation, the case is as I have stated it, and he far surpasses most other nationalities in his courage and endurance.

"The remarkable recuperative power of the Chinese after surgical injuries is unanimously testified to by all who have had to deal with them, and my experience of them goes to confirm this generally received opinion.

"The fact is to be discounted that, in the case of the poorer Chinese, a prolonged course of low living and practical starvation has frequently added its results to the original trouble (while the native practitioners are doing their best or worst) before the case is submitted to the Western surgeon, and this materially affects the progress of many of our patients; but, *ceteris paribus*, recovery and convalescence are very much more rapid and complete in the average Chinaman than in the average Englishman.

"Reasons for this difference are not entirely obvious, but the opinion may be hazarded that the simpler feeding habits of the Chinese, the rare occurrence of albuminuria or glycosuria, and their equable mental constitution, form at least some of the causes of the higher vitality of their tissues. The popularly accepted notion that the Chinaman lives on rice is indeed very far from the truth, since even the poorest manage to add a few green vegetables and a little fish or pork to the rice, which is the staple national diet; but, taken all round, the Chinaman's food is certainly more simple, and probably more nutritious, than the food of an Englishman under analogous circumstances, albeit his habit of consuming it wholesale renders him specially liable to dyspeptic troubles. His use of alcohol is also much less injurious to his tissues than is its use by a large proportion of Europeans. The native spirit, samshoo, is very extensively consumed, but it is invariably in minute quantities and never excepting with meals, intoxication being a thing practically unknown in China. Depending on this, doubtless, is the comparative rarity of albuminuria among the Chinese. Professor Grainger Stewart estimates the presence of albuminuria in Great Britain at 24 per cent. among the sick and 10.8 per cent. among the presumably healthy, yet in the Alice Memorial Hospital the proportion of cases showing the faintest traces of albumin does not exceed 5 per cent., and glycosuria is rare in the extreme. The tranquillity of the Chinese mind is proverbial. A Chinaman is never in a hurry. Provided he be given a hope of ultimate relief, it rarely matters to him whether his stay in hospital is to extend over a week or a month, and this absence of all worry probably goes far, along with the other facts I have stated, to account for the kindly reaction of his tissues under the surgeon's knife."

"In close relation with the Chinaman's habit under and after operation is the reaction of the Chinaman's system under the influence of anæsthetics.

"My Edinburgh training regarding chloroform having been fully confirmed by the results arrived at by the Hyderabad Commission, I have never used any other general anæsthetic, so that my experience of

chloroform administration to the Chinese now extends over many hundreds of cases, and I have not seen one in which it has been followed by harmful results.

"The Chinaman passes much more slowly under the influence of chloroform than the average Englishman, but usually without any of the excited stage through which the latter frequently passes. Any talking or struggling is quite exceptional. He passes, too, more readily from under its influence, so that its administration requires to be more continuously maintained. He is much less liable to the nausea and vomiting that so frequently follow the use of the drug elsewhere, and I certainly have never seen it in its severer forms since coming to China. In a word, it is a safer and a more agreeable task to administer this general anæsthetic to the Chinaman than to the Englishman, but for the one drawback that the time the former takes to yield to its influence is sometimes trying to one's patience and wasteful of one's time.

"As to *local anæsthetics*, the ether spray has in my hands been useless, either on account of the climate or peculiarity of the Chinese, but cocaine I find a perfect anæsthetic for purposes of minor surgery, and have not known any injurious results attend or follow its use.

"Having considered the Chinaman from the point of view of operative surgery, I shall confine my further notice of his surgical characteristics to a mention of four of the occasional sequelæ of operation from which he enjoys a comparative exemption.

"Erysipelas is seldom met in South China, being in some ports quite unknown, and it is also infrequent in the North, though there in warm winters it occasionally tends to become epidemic. In the Canton Hospital Report for 1874 Dr. Kerr remarks that he had up till that year seen but one case in a twenty years' very large experience. I have never seen it follow operation, and in the three or four cases I have met during the past three years, all in the face and scalp, no breach of surface could be traced as the starting point excepting in my last such case.

"Tetanus is also infrequent in adults, though a vast proportion of the native infant mortality is caused by the form of it known as tetanus neonatorum. I have met but a single case. A man came from the country suffering from the effects of an explosion, having carried away the right hand a week previously, in which the stump was gangrenous and dysphagia already present. I amputated high in the forearm, and tried by means of general treatment to avert the tetanic symptoms, but failed, the patient dying in a condition of general tetanus a few days later.

"Hæmophilia is extremely rare in China. One or two cases are on record, but these the hæmorrhagic diathesis present in anything like the proportion in which it exists in other regions it must have much oftener presented itself at the many centers of surgical work now existing in the empire. I have personally met no member of the family of bleeders.

"Urethral fever is unknown in China. Venereal disease, with its resultant strictures, is enormously prevalent, and probably nowhere in the world is vesical calculus more common than it is in the province of Kwang-tung, off the coast of which Hong Kong is situated (though curiously the disease is almost unknown elsewhere in China). Consequently in the Alice Memorial Hospital sounding and catheterization are events of daily occurrence; yet in not one single case have I observed the fever that so frequently is the concomitant of similar operations in Great Britain. The Chinaman's phlegmatic temperament seems to extend to his urethra.

"It does not come within my purpose in this paper to discuss at length the *special surgical conditions met with in the Chinese*, but within a single paragraph one or two remarks on the subject may suitably find place.

"The absence from China as yet of the railway, of heavy machinery, and of almost all mode of conveyance but by manual labor or by boat, makes the proportion of cases of serious accident—*e. g.*, of bone lesions—very small. Tumors abound, simple tumors of all varieties predominating, sarcoma coming next in frequency, and epitheliomata being comparatively seldom met with. Hernia is common, but strangulation or other form of intestinal obstruction rarely occurs. I have already incidentally remarked on the frequency of vesical and urethral calculus in Kwang-tung province and its absence elsewhere. All

forms of elephantoid disease abound, but, excepting in case of the scrotal form, surgery offers it small hope of relief. Deformities resulting from rickets I have seen only in one or two instances, but tubercular diseases, and especially of the hip joint, are painfully frequent.

"Finally, surgical conditions depending on chronic conjunctival inflammations are the most common of all that come under treatment."

Quasi-insanity in Children.—At the last meeting of the Medical Society of Pennsylvania Dr. Charles K. Mills, of Philadelphia, presented a paper on Some Forms of Insanity and Quasi-insanity in Children. In advance proof-sheets of the society's *Transactions* we find the following under the subheading of Quasi-insanities:

"In a philosophical sense sanity and insanity are relative terms whether applied to children or adults. Certainly not a few may be properly regarded as on the borderland between mental health and disease, and these are perhaps best classed as examples of partial or quasi-insanity, forms of mental disease which in a certain manner and degree have the attributes of insanity. Quasi-insanity better expresses the idea than such terms as partial or pseudo insanity, or borderland cases, for the prefix 'quasi,' as used in English, indicates that the thing spoken of resembles or has the attributes of something without being the latter in the full sense. Some of the best examples of quasi-insanity are to be seen in those suffering from those affections which are shown by morbid doubts and morbid fears, and have been described under many names, as *folie du doute*, introspective insanity; or as phobias in endless train—claustrophobia, agorophobia, pathophobia, pantophobia, etc. Some knowledge of these phobias and of what they import might be of value to many of my brethren not neurologists—to gynecologists and surgeons particularly. They are psychoses, which lead sometimes to oophorectomies and laparotomies, to uncalled-for operations and treatments of various sorts on all parts of the body. They are abortive or imperfectly developed mental disorders. Sometimes they are as transient in duration as they are limited in phenomena; but in other instances a few elementary deficiencies or disturbances may persist without much change or increase through life. Many of these cases, like certain morbid impulses, belong under the general head of paranoia. They have been described not only as morbid fears or phobias, and as morbid doubts or abulias, but also as emotional monomanias, and even as forms of neurasthenia. They are fundamentally dependent upon the domination of the mind by morbid concepts and insistent ideas.

"They are sometimes observed among young children, although more common after than before the period of puberty. Their most striking illustrations occur in those who have not been subjected to any physical or mental strain sufficient to break down a healthy organization. Persistent fear of the monomaniacal type occurring in children is rarely due to overwork at school, as is frequently supposed. The cause is generally in the child's progenitor or progenitors.

"Not infrequently several of the so-called varieties are present at the same time, in the same case, and some cases belong to a class which has been well described as pantophobia, or fear of everything.

"As to cases observed in comparatively young children, Hurd reports one from an account written by the patient herself. When about twelve years old she began to have strange fancies, as fearing that the blood flowing from a cut finger would harm those who came near her. Later, dressing, walking out of doors, eating, were all greatly interfered with through the same morbid ideas. She feared contagious disease because she might communicate it to others. The insistent idea changed from time to time, but seemed to spring always from the emotion of fear. She eventually recovered. Hammond cites from King, of Sedalia, Missouri, an interesting case of pyrophobia in a boy of ten years old. Day and night he was infested with fear of this kind. On one occasion when the morning was cool he succeeded after a contest with his mother in opening the stove door and pouring a bucket of water over the fire. He is said to have been cured by quinine, the bromides, and the use of evaporating applications to the head.

"A boy, eleven years old, developed what was practically a pantophobia, although his disorder exhibited itself chiefly as a pathophobia, or fear of disease. He was kept almost constantly in the hands of physicians. Sometimes his morbid ideas revolved around real affections of slight importance; sometimes his fears and suffering were

due purely to morbid conceptions and insistent ideas. Now his eyes were the source of morbid dread, and soon his limbs were the seat of rheumatic pain; he narrowly escaped, after solemn consultation, a laparotomy for 'typhlitis,' a case of strange metastasis, as the typhlitis was probably in his head. To a moderate degree he suffered from mysophobia, spending unusual time at his ablutions, teeth cleaning, dressing, and in the care and arrangement of his clothes. Anything in the nature of a symptom or a disease mentioned in his presence was likely to take possession of him. His morbid notions and apprehensions were fed and encouraged by the unceasing attention of members of his family. He was the only son of a widow, and was under the tutelage of a mother, a maiden aunt, and a grandmother, probably the worst board of management for a pathophobic boy that could have been chosen by perverse fate. He was practically cured by taking him from his home surroundings, disregarding his complaints, forcing him to do things on time and after the manner of others, at the same time carefully but not obtrusively looking after the general health.

"Another boy, at the age of ten, began to develop the scrupulous and mysophobic type of monomania; in fact, he was, as so many of these cases are, an illustration of an admixture of several of the so-called classes of morbid fears. He was constantly worrying about many things that he said and did in his intercourse with others. If left alone, he would spend hours in bathing and washing himself; and often imagined that he had been polluted or would contaminate others. The symptoms were in many respects like those of the lady described by Hammond, and to whose case he first applied the term mysophobia—who could touch nothing without being irresistibly impelled to wash her hands, and who in many other ways was tormented by the fear of contamination. This boy improved greatly under mental discipline, outdoor exercise, and careful tonic medication.

"It may be necessary sometimes to separate a form of *juvenile dementia* the result of *inherited syphilis* from idiocy and imbecility, whether of syphilitic or other origin, which may commonly be done by the fact that the dementia usually comes on after the child is four or five years old, and therefore when the mental condition has been determined not to have been that of idiocy. In rare cases, it happens that a juvenile or infantile dementia occurs when the child is two or three years old—so young that its true mental status has not been fully determined. With this word of caution as to the possibility of inherited syphilis showing itself in a child otherwise healthy in the first year or two of its life, most of the cases of this form of dementia will be comparatively easy of recognition. A family history of syphilis will often but not always be obtained. Often the upper incisors will be pegged and notched, and cicatrices at the angles of the mouth, and the characteristic physiognomy be present; the child will have attacks of keratitis, chorioiditis, or iritis, or a history of snuffles, or of a rash; and sometimes epilepsy will have developed."

The Evolution of Surgical Principles was the subject of Dr. G. H. Hume's address in surgery, delivered on August 3d before the British Medical Association. In the course of his address, for advanced proof-sheets of which we are indebted to the *British Medical Journal*, Dr. Hume said:

"It is our frequent boast that surgery has become, and is becoming, more scientific, and by an appeal to our results we justify the claim. But the science of surgery—and by the phrase we mean the principles of surgery—is nearly altogether the growth of the century that has followed Hunter's death, and its growth has been by no means one of continuous or steady progress—rather, as is usually the case in the development of scientific truth, it has been by fits and starts. The greater part of the work has been done in our own generation. And now, with regard to much of the art of surgery, it rests on principles so worked out and firmly established that the claim to scientific position can be made good. But with regard to much also we are still only struggling toward scientific truth. In speaking, therefore, of the development of surgical principles I shall endeavor to illustrate both classes—both those principles which, being in a sense perfected, have issued in enhanced success; and those also toward which we are still groping, and by which we have not yet been guided out of difficulty and uncertainty.

"The 'principles of surgery' is one of those elastic phrases which carry to our minds a fairly exact meaning, but to which we find it hard to give a concise definition. We certainly do not use it as the equivalent of theory. The surgeon who, thinking himself well versed in surgical principles, and therefore prepared to act in the best manner for the best reasons, would not consider himself justly described as a man of theory. And yet theories which become the motive or suggestion of surgical action are surgical principles, and these may be sound or unsound according to the character of the views upon which they are based. In so far as surgery is applied science, the data from which surgical procedures spring are in the strictest sense scientific principles; and we find that surgery advances by precisely the same methods as all other practical sciences. We have our inventions, our appliances, our practical details upon which an ever-increasing ingenuity and industry are expended. We have also sometimes our discoveries in medical or collateral science, which become the inspiration or rallying point of great practical advances. But the phrase covers more even than scientific data. The definite ends or objects of surgical action which are proper under given circumstances belong to the principles of surgery. So also do rules of procedure which the gathered experience of the past and present prescribes or sanctions. The mode of formation of surgical principles is therefore a double one. They may arise like a superstructure upon a foundation of scientific knowledge, or they grow down out of experience to be themselves part of the foundation. They are the mainsprings of action; and so far from being alien to practical efficiency, they are at once its inspiration and guide. One of the not least important surgical principles dictates scrupulous attention to the minutest practical detail; and he who, knowing that a life may hang on the integrity of a stitch, concerns himself anxiously about the method or material of a suture is only acting in faithful obedience to surgical principle.

"The mode of growth of scientific principles can find no better illustration than in our modern doctrines of surgical repair. The beginnings of these doctrines may be traced far back in the history of surgery. But it was by Hunter's work and in the pages of that *Treatise on Inflammation*—which, though pondered and labored through many previous years, as was Hunter's way, was not published till the year of his death—that the real beginning was made. Hunter's statement that 'primary healing takes place without inflammation' contains the germ of what we believe and act upon now. It did not, of course, go far enough. It defined the relationship between what was then, as it is now, ideal healing and inflammation, in the sense that no relationship can or does exist between them at all. But there is no such definite expression to be found in Hunter's writings with regard to the modes of secondary healing. Hunter, I think, believed, as did most of his successors down to the last few years, that a certain degree of inflammation was necessary for these delayed forms of healing. Indeed, from Hunter's time there was a falling away from the faith, and we find the most philosophical surgical opinion as represented by Travers holding that a 'subdued state of inflammation favors healing,' and that to 'supersede it would effectually retard or preclude' the process of repair.

"I am sure, sir, that to many in this audience it may seem to demand an apology that I should even mention in their hearing the name of inflammation. I may appear to be abusing my opportunities in carrying them back to their earlier days when inflammation was the bugbear of their surgical studies, a true surgical *pons asinorum*. But I plead in excuse that down to a recent period the ideas of healing and the ideas of inflammation seemed in the very nature of things to be inseparably interwoven. It turns out that they were only needlessly entangled, and ideas which in the time of their confusion belonged mainly to the region of theory have since proved to be matters of the most eminent practical importance. The process of disentangling began in and proceeded with the elucidation of the true nature of inflammation and its consequent suppuration. There was a time when the four classical symptoms of pain, heat, redness, and swelling summed up nearly all that was known of the process of inflammation. Then followed the anatomical era, the time most fruitful of bewilderment to the student, in which, thanks to rapid improvement in the methods of microscopical investigation, attention was concentrated in the blood

stasis, the changes in the tissues and in the vessel walls, and on the out-wandering of the white corpuscles. An intermediate stage followed this in which, clinically and experimentally, the suppurative processes were recognized to be infective in their nature. And this culminated on the period in which we now find ourselves when the whole process is demonstrated to be due to the agency of micro-organisms. One point, however, remains to be cleared up. Is the febrile access which follows an aseptic operation, sometimes sharp in degree though short in duration, to be looked on as the result of inflammation? There is no ground for supposing it to be an infective process the same in kind and differing only in degree from that which always tends to suppuration. If different in nature it should also be distinguished in name, and there is much to justify the proposal to restrict the word inflammation to those changes which result from the action of septic organisms, while the other and simpler process under some such title as traumatic reaction demands further examination for the clearing up of its intimate character. Such a defined use of the term would end the confusion which has hitherto attended the conception of inflammation as a disease, and would rest the idea to which the word corresponds on the sure ground of etiology.

"Naturally with the true knowledge of inflammation and suppuration have come clearer and more accurate views with regard to the process of repair. Not alone in primary adhesion but in all forms of healing it is seen that inflammation is never a help, and can only be a hindrance, and that if it occurs repair must take place in spite of it, or be delayed until it has passed away. We have gone back upon Hunter's dictum, only we have given it a more extended, or rather an unrestricted, application. The surgeon's part, therefore, is now not to treat but to prevent inflammation and suppuration, and the practical side of the scientific evolution I have briefly sketched is the antiseptic system."

The Utilization of Criminals for Experimentation.—Dr. W. A. Gordon, of Oshkosh, Wis., recently delivered a presidential address before the Brainard Medical Society in which he set forth some radical if not quite novel aspirations. From the address, as reprinted from the *Milwaukee Medical Journal*, we extract the following:

"Pettenkofer is studying cholera. The other day he wished to test the effects of certain cholera bacilli on the human body. But in all Europe there was no body he could use, and so he took his own.

"Thrice illustrious scientist! Sublime enthusiast!

"In every country in Europe are men waiting to be shot or hung. They should have been given to Pettenkofer. He should not have been allowed to risk his useful life. One Pettenkofer is of more value than all the unhung assassins on earth.

"In the United States between two hundred and three hundred persons are annually executed by law. To ruthlessly destroy the bodies of so many criminals, when they might be, and ought to be, used for the advancement of science, is one of the most notable extravaganzas of this utilitarian age. It is an absurd custom, inherited from our ignorant and savage ancestors who knew nothing of bacteria and the value of vivisections.

"The base Indian threw a pearl away
Richer than all his tribe."

"In the eyes of the devout physician this shameful, inexcusable waste of first-class physiological material is itself a crime. It is undoubtedly proper to exterminate murderers and rapists for the protection of society, as we do Canada thistles, rattlesnakes, and other noxious things; but the criminal is a man, and as such, even if he has forfeited his life, is entitled to die by some of the processes ordained by Nature for the destruction of human life.

"Benjamin Franklin said that a man is not fully born until he has passed through death. If this utterance of one of the most philosophic intellects the world has ever seen is true, every man has an inalienable right to die by some of Nature's methods. Then no convention has the right to decree the instantaneous annihilation of a human being. Death is supposed to be a profound spiritual process, whereby the soul is at least partially schooled for the momentous concerns of eternity. In that supreme hour the passions, prejudices, hopes, and fears of this

naughty world have lost their influence. The solemnities of the great hereafter fill the parting spirit with awe and expectation.

"Death is an experience laden with such great possibilities that no man should be willfully deprived of all the benefits it may bring to him.

"Electrocution and strangulation terminate life so quickly that the benefits that may accompany dying are lost.

"The condemned criminal is usually in the full tide of physical vigor, and until the last moment expects pardon or postponement. But when an invalid feels the skeleton hand of death upon his vitals, he knows there is no pardon and no escape.

"All forfeited lives should be ended gradually by some of God's methods.

"There should be established in several cities in this country prison laboratories or experiment stations, where men who have been condemned to death can obtain death at the hands of competent physiologists and pathologists. These institutions should be as secure as prisons and supplied with all the appliances and instruments of precision required by biological science in its most delicate examinations. Here all new remedies should be tested and all new treatments tried upon the bomb-throwers and cutthroats who are now so inconsiderately hanged. In these prison laboratories criminals should be infected with diphtheria microbes and then experimentally treated. They should be infected with the micro-organisms that produce typhus and typhoid fevers, cholera—in fact, all germ diseases—and then experimentally, rationally, and scientifically treated, and mankind have the benefit of the information obtained. There should be inoculation and other experiments relative to the nature and cure of cancerous affections. There should be an endless number of experiments upon the nature, prevention, and cure of the greatest destroyer of human life—tuberculosis.

"In these laboratories the limitations and the possibilities of pulmonary and cerebral surgery should be definitely marked out.

"There are various questions concerning the pneumonias that urgently require solution.

"The localization of the cerebral functions as to mental and moral, as well as motor, operations needs to be thoroughly studied by some of the masters of brain physiology.

"Gastric, biliary, and intestinal fistulae should be established for the exhaustive study of all digestive processes.

"One of the most fruitful fields for research would be the antagonisms of the schizomycetes. Sarcomas are said to be favorably modified by infections with erysipelas microbes. Cancer and tubercle are said to be incompatible.

"Numberless experiments on the reactions of bacteria upon each other need to be made.

"There are many experiments that can only be satisfactorily made on man. The use of dogs and other animals is accompanied by so many sources of fallacy that they can only be used for certain lines of work, chiefly of a mechanical character.

"Of course, in all these investigations the divine influences of chloroform, cocaine, ether, and opium would be employed whenever possible to prevent suffering in the subjects.

"The idea that malefactors should be favored with a painless and rapid death is a mere schoolgirl sentimentalism. Even if death were the end of all, there is no natural reason why the worst men should have the easiest deaths.

"Every experiment should be, and would be, conducted gently, the murderers treated courteously. They should be carved tenderly, but thoroughly.

"The hysterical, effeminate persons who constitute the anti-vivisectionist contingent should have the privilege of sending bouquets and confections to the victims, as they now do to every scurvy vagabond who is awaiting execution.

"The ministrations of the clergy should be encouraged. The abolition of the effusive and theatrical clerical exhibitions on the scaffold would be one of the reliefs to the world that this method should bring.

"A diminished amount of crime would undoubtedly follow. The melodramatic descriptions of 'game' deaths would not regale and encourage impending criminals. Dying in bed from a common, every-day

disease does not appeal to the dramatic element of the criminal mind. The gallows would be shorn of its fascination.

"When the profession, through its journals and societies, points out to the people the great benefits to society that can be obtained by the scientific use of forfeited lives, the public common sense will quickly turn to good account this source of profit to itself.

"The anti-vivisectionists themselves will probably come to favor this plan, for it would save some dogs from the knife, and they, valuing dogs more than men, would take the least of two evils.

"A large number of Christian people will undoubtedly favor it, because its soul-saving capabilities are greatly superior to barbaric strangulations.

"Scientists and humanitarians must approve of it on account of its many intrinsic excellencies.

"That knowledge of inestimable value to the present and all future generations of men can be obtained by the adoption of this scheme is certainly true."

To Contributors and Correspondents.—*The attention of all who purpose favoring us with communications is respectfully called to the following:*

Authors of articles intended for publication under the head of "original contributions" are respectfully informed that, in accepting such articles, we always do so with the understanding that the following conditions are to be observed: (1) when a manuscript is sent to this journal, a similar manuscript or any abstract thereof must not be or have been sent to any other periodical, unless we are specially notified of the fact at the time the article is sent to us; (2) accepted articles are subject to the customary rules of editorial revision, and will be published as promptly as our other engagements will admit of—we can not engage to publish an article in any specified issue; (3) any conditions which an author wishes complied with must be distinctly stated in a communication accompanying the manuscript, and no new conditions can be considered after the manuscript has been put into the type-setters' hands. We are often constrained to decline articles which, although they may be creditable to their authors, are not suitable for publication in this journal, either because they are too long, or are loaded with tabular matter or prolix histories of cases, or deal with subjects of little interest to the medical profession at large. We can not enter into any correspondence concerning our reasons for declining an article.

All letters, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication. No attention will be paid to anonymous communications. Hereafter, correspondents asking for information that we are capable of giving, and that can properly be given in this journal, will be answered by number, a private communication being previously sent to each correspondent informing him under what number the answer to his note is to be looked for. All communications not intended for publication under the author's name are treated as strictly confidential. We can not give advice to laymen as to particular cases or recommend individual practitioners.

Secretaries of medical societies will confer a favor by keeping us informed of the dates of their societies' regular meetings. Brief notifications of matters that are expected to come up at particular meetings will be inserted when they are received in time.

Newspapers and other publications containing matter which the person sending them desires to bring to our notice should be marked. Members of the profession who send us information of matters of interest to our readers will be considered as doing them and us a favor, and, if the space at our command admits of it, we shall take pleasure in inserting the substance of such communications.

All communications intended for the editor should be addressed to him in care of the publishers.

All communications relating to the business of the journal should be addressed to the publishers.

Contributors who wish to order REPRINTS of their articles should do so on a blank prepared for that purpose, which will be sent to them by the publishers on receipt of a request to that effect. The order should be sent to the publishers, and not to the editor.

Lectures and Addresses.

ANNUAL ADDRESS OF THE PRESIDENT,

READ BEFORE THE
IOWA AND ILLINOIS CENTRAL DISTRICT MEDICAL SOCIETY.

By W. L. ALLEN, M. D.,
DAYENPORT, IOWA.

DURING the past twelve months we have watched anxiously the progress of the existing cholera epidemic in Europe. We have seen one of the most successful battles ever fought by scientific medicine with a dread disease; fought in New York Harbor and followed up in the city of New York by medical men who were hindered by the conflicting interests of numerous corporations, by personal appeals, bribes, and direful threats of thousands of passengers, by interfering officials, and malignant wirepullers. In August and September of 1892 there were 17,000 patients with cholera in Hamburg, of whom 7,600 died; there were 80,000 persons inspected at Quarantine in New York Harbor during the six weeks ending October 14th. As an additional source of danger, 76 died on the voyage from Hamburg and 44 in the harbor of New York. And yet from all these many sources of contagion only 11 isolated cases occurred in New York city, where, although widely separated in various parts of the city, the disease was stamped out and not one point of infection was left. Never was the country in greater danger, nor the battle more successfully fought and won. I am proud of the great achievement, and proud to say that the credit belongs to the faithful workers in scientific medicine—men who for the past thirty years have labored unceasingly to find the *cause* of each disease; men who have made post-mortems by the thousand; have examined each part infected by chemical tests and by the microscope; men who have ruined their health working over specimens of tuberculosis; have carried their apparatus and lost their lives in India studying the disease in its most dangerous strongholds—these men, the pathologists of scientific medicine, have been the ones to say the cause of cholera is the cholera bacillus. Only by quarantine of the individual and by killing of the germs by heat or strong and poisonous solutions can the disease be prevented.

For over two thousand years the allopathic and the homeopathic schools (the former called "the old" by the latter, which styles itself "the new school") have treated *symptoms*, and have never admitted a ray of light whereby we might work to prevent or finally blot out a given disease. Not one of the disciples of Hahnemann has succeeded in annihilating a single cholera germ.

Were the medical profession in India as well supported and backed up as the profession is in Germany and France, there would not be a case of cholera on the face of the earth. That unfortunate country, with its system of tanks and pools in which the inhabitants bathe and wash their clothes and from which they drink, with privy vaults on the borders of these same pools, with a germ-breeding climate, with religious ceremonies bringing together thousands of pilgrims from all parts of the continent—all of

these evils could be blotted out or corrected and cholera would practically disappear.

I desire now to call your attention to a disease that is troubling us continually—I mean, of course, diphtheria. During the past ten years there have been two thousand and sixty-eight cases of diphtheria in Davenport, with five hundred and eighty-four deaths therefrom, thus fifteen per cent. of all deaths being from diphtheria. During two years of this period thirty per cent. of all deaths were from this cause. This is very much worse than in New York city, where, although thirty per cent. of the diphtheria cases were fatal, the number of deaths from diphtheria was only five per cent. of the deaths from all causes.

I believe (1) that we do not, *as a rule*, treat the disease scientifically so far as internal medication is concerned; (2) that while we know how best to apply thorough local treatment, we do not carry out the same in a way satisfactory to ourselves, nor for the best interests of the patient, and we do not receive remuneration commensurate to the time, labor, and risk involved; (3) that our local boards of health are not given the power to aid as they should in preventing this disease. In support of these statements, (1) there is present in and about the pharynx, larynx, or nasal cavity, in all cases of diphtheria, the diphtheria bacillus. We do not suspect its presence until we can see an exudation on the parts affected. This bacillus does not, like the bacillus of cholera, invade the blood and pass into various internal organs, but there is at once produced by its existence locally in the throat a ptomaine which is quickly absorbed and which passes throughout the system. Our *internal* medication has been iron, quinine, alcohol, and strychnine as stimulants and blood restoratives, all of which are good; and as specifics, chlorate of potassium, corrosive sublimate or other preparations of mercury, benzoate of sodium, and salicylic acid. The use of potash has been entirely abandoned, it being inert and affecting neither the bacillus nor the ptomaine, and exceedingly liable to cause nephritis. The mercurial preparations show by their action on the bacillus, theoretically, the best advantage, but as yet we have no knowledge as to their effect on the ptomaine.

For nearly ten years these various mercurial preparations have been given a fair and thorough trial, and although their local effect is undoubtedly most favorable, I doubt if the results will show much if any benefit from their internal use. I may use the same argument against salicylic acid and benzoate of sodium, both of which are so generally used in Europe; we are consequently as we were ten years ago—without a specific. (2) Locally, we have most effectual weapons in peroxide of hydrogen, corrosive sublimate, and salicylic acid, used best as spray, and in the application to the throat of methyl violet, chloride of iron, etc. The nose and throat can be most thoroughly cleansed, the exudate entirely invaded and partially dissolved, by spray with peroxide of hydrogen, followed by corrosive sublimate. To do this it is not sufficient for the physician to pump a few minutes at the atomizer or swab out the throat with a wad of cotton, which reaches at most less than ten per cent. of the surface involved, knowing that

our object is to kill every single bacillus within the nasal cavity and pharynx within twenty-four hours of our first visit; to do this five or ten minutes with the spray or douche twice a day will not avail. To instruct the nurse or parents will be no better. To accomplish our object, every particle of exudation must be softened and thoroughly impregnated with the spray solution. You all know that you have occasionally done this, but not as a rule, because it requires you to devote almost your entire time to these cases for the first three or four days; to make four visits each day—visits requiring hard work and full of danger; it requires that you place yourself in such a position that you are certain to receive upon your face, hands, and clothing particles of infected material; it requires that you must, in justice to yourself, your family, and your other patients, wash and disinfect your hands and face, hair and beard, and change your clothing. This is no exaggeration. I believe that it is the duty of this society to see that such methods are adopted; that this can be done, that every case of diphtheria requires four visits a day by a physician who will personally perform or superintend the proper local treatment; that the time and danger thus involved should be compensated for in some measure by a fee of five dollars for every visit, which visit is to be one of personal work and danger, and that those who can not afford such treatment should be given it by the city or county. Look at the facts—look at the array of statistics! The New York papers have been full of reports of a severe epidemic of typhus fever, from which during the last six months there were 189 deaths; during the same time there were in New York 1,042 deaths from diphtheria out of 3,113 cases. Nothing is thought of this. Twenty years ago there were 85 deaths from cholera in this city, and since then there have been 4 deaths from small-pox. Our city and county authorities arose in alarm and built a pest house; it has been used but once since, although there have been 600 deaths from diphtheria—more than we shall be likely to have from small-pox and cholera during the next century. The mortality from cholera in Hamburg was less than forty per cent.; from small-pox it has recently been less than twenty per cent.; diphtheria is more fatal than the latter and nearly as fatal as the former; why, then, should not diphtheria cases be treated with the same consideration? At the last meeting of the Mercy Hospital Board a resolution was passed giving diphtheria such consideration and allowing the attending physician the same fee as in cholera and small-pox cases. (3) Our board of health should be given the fullest control over such cases. A great improvement has taken place in the last few years owing to better enforcement of quarantine regulations. The disinfection of diphtheritic houses should, however, be undertaken directly by the board. Such doubtful measures as sulphur fumigation should be discarded; to place reliance on a weak and doubtful measure is worse than no attempt, as a false security is felt and greater risk taken. The New York City Board of Health has just announced itself prepared and willing to make a microscopic examination of specimens of exudations of all diphtheria cases or cases suspected of being diphtheria,

thus making possible an early diagnosis of doubtful cases and insuring early and rigid quarantine. This is a step that will surely be followed by beneficial results. I would suggest that a map of our city be made at the end of every year marking the location of diphtheria. Especially would such maps be useful at this time, when certain dangerous localities are about to be supplied with sewers, and it is of importance that we should know the results that follow.

I urge the society to act promptly and forcibly in these matters, as I know of no others so urgently demanding our united efforts.

July 13, 1893.

Original Communications.

A NEW

DIAGNOSTIC SIGN OF TYPHOID FEVER.

By SIMON BARUCH, M. D.

THE excellent paper on the diagnosis of enteric fever in the *New York Medical Journal* of July 29, 1893, moves the writer to add an important diagnostic point which he regards as almost pathognomonic.

The great import of an early diagnosis of this disease is emphasized by the statement of Brand, Vogl, J. C. Wilson, and others that *the successful issue of the case is almost assured if the bath (Brand) treatment is inaugurated prior to the fifth day of the disease*. That this statement is justified by clinical evidence the writer has endeavored to impress upon the American medical profession. Since his paper before the New York State Medical Society in 1887, in which clinical evidence was based chiefly upon German and French practice, Wilson, of Philadelphia, Peabody, and Gilman Thompson, and Delafield, of New York, and Carl Sihler, of Cleveland, have offered American hospital and private records which confirm all that he alleged in the article of 1887. The latter was concluded as follows: "We stand on the threshold of an epoch in typhoid-fever treatment. The evidence before us is clear and incontrovertible. Upon our conscientious, unbiased, and fearless judgment and action rests the weal or woe of those who commit their lives into our keeping." The medical journals and hospital records of this country have verified this statement. Led by the eminent teachers who have cautiously tested and now recommend the Brand method, the American profession is slowly but surely becoming convinced of the marvelous difference in the mortality of typhoid fever induced by the early adoption of the bath treatment.

Since, however, the *diagnosis* of this disease is so difficult, how are we to act in this matter when a few days' delay are of such vital import to the patient?

The method adopted by the writer in hospital and private practice is as follows: So soon as a patient shows a rectal temperature above 102.5° in the morning and 103° in the evening for three successive days, especially if accompanied by headache, dullness, or apathy, he is placed into a full bath at 90°, which is reduced to 80°, with constant friction over the body. In three hours, the tempera-

ture still being above 102.5° , he receives another bath five degrees cooler. This is repeated until the temperature of the bath is 75° . If one or more of these baths fail to reduce the rectal temperature two degrees in half an hour, the diagnosis of typhoid fever is almost certain and the bath treatment is continued.

The point I desire to emphasize is that the *resistance of the rectal temperature to a bath of 75° for fifteen minutes with friction is an almost certain test of typhoid fever.*

I have diagnosticated a central pneumonia and an osteomyelitis by the bath; the records of these are to be found in the Manhattan Hospital case books.

In my last service—April to June, 1893—a woman was brought in with obscure symptoms and a history of over a week's illness. There being no spots visible, a diagnosis of typhoid fever could not be harmonized with the history. The baths given as here indicated reduced her temperature only about half a degree, and after the first bath the temperature *actually rose*. Despite the clinical history, a diagnosis of typhoid was made. This was confirmed by the appearance of a few spots two days later, and a large daily crop afterward. The patient passed through a severe type of the disease, with slight hæmorrhage, during which baths were stopped; heart failure, which was relieved immediately by affusions at 70° in a dry tub, and a pronounced *status typhoides*, which was removed by the bath and returned when the latter was suspended on account of streaks of blood in the fæces.

In another case, a gentleman, just arrived from Havre, whom I had the pleasure of seeing in consultation at the Hoffman House with Dr. P. Pease, in August, 1892, with physical signs of pneumonia, the temperature rose from 105° to 106° after a half-hour graduated (Ziemssen) bath (95° to 68°). Upon this ground I ventured the diagnosis of typhoid, which was confirmed in a few days by positive evidence. This patient proved so refractory under the baths that the latter were desisted from, because he had no relatives to whom we could appeal for sustaining our apparently heroic treatment.

In conclusion, I desire to refer to the clinical fact first pointed out in *The Use of Water in Modern Medicine*, that after the cold bath the mouth temperature shows a difference of one degree and a half to two degrees from the rectal, and not a half to one degree as is usual.

If the rectal temperature before and after a bath of 80° to 75° is not reduced at least one degree in half an hour, the diagnosis of typhoid may be safely made, if other symptoms point ever so slightly in this direction. Hence the diagnosis of this disease should no longer be obscure even in the first days of its course.

Movable Kidney with Hydronephrosis.—In an article on this subject, published in the *International Medical Magazine*, Dr. D. W. Graham makes the following conclusions: "1. Intermittent hydronephrosis is a frequent sequel of movable kidney. 2. Mental disquietude may be the only symptom of a movable kidney or hydronephrosis. 3. On the other hand, there may be functional disturbance of every neighboring organ. 4. Disturbance of the functions of the kidneys may be less marked than that of the other organs. 5. Hydronephrosis is a progressively destructive condition. 6. Nephrorrhaphy is indicated as a preventive measure even when not called for by the severity of the symptoms *per se*. 7. Hydronephrosis once developed is most effectually and safely treated by lumbar nephrotomy and drainage. 8. Nephrectomy for hydronephrosis is not warranted unless the kidney substance is completely destroyed or the ureter is impervious."

THE TREATMENT OF TYPHOID FEVER, BASED ON ITS ETIOLOGY.*

By T. J. SHUELL, M.D.,

PARNELL, IOWA,
MEMBER OF THE AMERICAN MEDICAL ASSOCIATION.

THE ætiology of typhoid or enteric fever has been under discussion for many years. Many writers, like N. S. Davis, have contended that the peculiar poison of typhoid fever originates *de novo* from the decomposition of organic matter.

To use Dr. Davis's own words (1): "Probably no fact is better established than that the disease under consideration (typhoid fever) generally originates from the use of air or water impregnated with some one or more of the products derived from the decomposition of organic matter."

The recent researches of Eberth, Klebs, Koch, Gaffky, and Vaughn have, in the minds of a majority of the medical profession, established the opinion that typhoid fever is due to specific micro-organisms or bacilli. From Eberth's careful investigation of this subject the term bacillus of Eberth is in vogue.

Probably many of us have seen cases of typhoid fever in which it would be extremely difficult to trace to a specific source; cases of persons who resided in the country districts and had not been off their farms for months or come in close proximity to cases of typhoid fever for years.

The advocates of the germ theory of the causation of typhoid fever maintain that the bacilli are brought into the system through the medium of food or drink. They cite numerous instances in which epidemics of typhoid fever resulted from the drinking water being contaminated by the specific poison of typhoid fever derived from the fæcal excreta. They hold that the bacillus of Eberth must be present in every case, and that, notwithstanding the pollution of drinking water by animal or vegetable decomposition, if the bacillus of Eberth be not found, typhoid fever will not follow.

As a compromise between the advocates of the germ and the anti-germ origin of typhoid fever, it is held by some (2) that the benign *bacillus coli communis* normally existing in the large intestine is converted, when out of the body, by thermal or atmospheric influences into the deadly typhoid germ—the bacillus of Eberth. Careful observations and clinical data have not thus far supported this theory.

Instances, however, like the Plymouth (3) epidemic of typhoid fever in 1885, carefully investigated by Dr. French and Dr. Shakespeare, two competent bacteriologists, would leave but little room for doubt that typhoid fever owes its causation to the presence of a specific micro organism.

Accepting, then—as do probably nine tenths of the medical profession—that typhoid fever is caused by the entrance of a specific micro-organism into the alimentary canal, I wish to go a step further and inquire whether the

* Read before the Des Moines Valley Medical Association, at Ottumwa, Iowa, June 15, 1893.

mere presence or mechanical irritation of the bacilli causes the nervous symptoms, or whether they are due to the ptomaines which the bacilli produce.

Professor Osler (4) says: "It has not yet been definitely determined whether the constitutional disturbances in typhoid fever depend upon the toxalbumins produced in the growth of the bacilli, though this is in the highest degree probable." Frederick P. Henry (5) writes: "It is now established that these substances (alkaloids or ptomaines), the toxicity of which is thoroughly proved by experiments on animals, are greatly increased in typhoid fever, and it is held by many clinicians that they are largely responsible for the group of symptoms known as 'typhoid.'"

Professor J. C. Wilson (6) writes: "It is probable that certain of the intestinal symptoms of enteric fever are due to a direct action of the typhoid bacillus, but the constitutional symptoms, including the fever, must be explained by the continuous action of a chemical poison produced by the growth and multiplication of these organisms within the body; especially is this true of the nervous and vasomotor phenomena, the feeble circulation, dirotism, relaxed capillaries, flushed face, dilated pupils, and delirium."

The fact that there is a prodromal or incubative stage of from a week to ten days in cases of typhoid fever—during which period there is a multiplication of the bacilli and a hyperplasia and thickening of Peyer's patches, more particularly in that part of the small intestine near the cæcum; and the further fact that the severe nervous symptoms and fever do not show themselves until the specific ptomaines are found in the large intestine—would induce one to believe that the symptoms known as "typhoid" are caused by the absorption of the poisons known as ptomaines, typho-toxines, or toxalbumins, and that the absorption takes place principally from the large intestine.

We can readily believe that the swarms of bacilli are but manufactories for producing the deadly ptomaines, which are carried onward by the vermicular action of the intestines and cause, by their mechanical irritation, diarrhoea; and by their absorption, fever, delirium, and nervous depression.

Reasoning from physiological facts, we know that all ingesta are retained but a short time in the stomach (from two to five hours), a comparatively short time in the small intestines, while in the large intestine they are retained in part for days and sometimes weeks.

The colon is admirably adapted as a receptacle for the *débris* of the intestinal tract. It is fitted out with sacculi or pockets, that may be likened to the stagnant bayous along our streams.

The lesions of typhoid fever are found mostly in the ileum, but the glands of the cæcum and colon, according to the best authorities, are affected in about one third of the cases (7). The manufactories for the production of the poisonous ptomaines are located principally in the small intestines, but the toxic products are stored away in the colon. Here, then, are the foci whence the poison of typhoid fever principally pervades the system.

Assuming this etiology of typhoid fever to be correct, a rational method of treatment at once suggests itself.

The indications for treatment will range themselves under three headings in the order of their importance.

1. To remove, at as early a date as possible, all ptomaines and decomposing substances from the colon.

2. To destroy or neutralize the effect of all micro-organisms above the cæcum by proper internal germicides, if any be found that will not impair the animal economy.

3. To enforce proper dietary and to treat rationally symptoms and indications as they may arise.

The first indication may be met only by thorough irrigation of the colon. But thorough irrigation of the colon can not be effected unless we pass a tube above the sigmoid flexure (8). The ordinary colon tube may be used, but I prefer a soft-rubber tube of a caliber of from 25 to 32, American scale, and about three feet in length. Excellent tubes for this purpose are manufactured by George Tiemann & Co., of New York city.

By attaching this to a fountain syringe and permitting, while it is being introduced, the stream to flow, it may readily be made to pass the sigmoid flexure of the colon and reach to, or near, the cæcum. The water used should be warm and aseptic, which can be effected by boiling. Only in exceptional cases should it be made antiseptic for fear of producing systemic poisoning. At least half a gallon of water should be injected in adults. The injection will distend the gut, remove the accretions from the sacculi, and result in such an evacuation of foul-smelling fæces intermixed with scybæ as will surprise both patient and physician. These injections to effect the most good should be employed early in the disease, before the high fever and severe nervous symptoms show themselves. They may be repeated, if necessary, at intervals of three days for the first week or ten days. The only precaution is that they should be used warily when the stage of necrosis of the glandular tissue is reached, as the solitary glands of the large intestine are affected in a large proportion of cases.

Having treated several cases of typhoid fever during the summer and autumn of 1892, I made this observation: that in every case in which I employed thorough irrigation of the colon at an early date such cases were rendered comparatively light. While such cases were not materially shortened in duration (though I believe a few were), yet they lost the typical typhoid picture of our text-books, the lassitude, the subulturn tendinum, the delirium, the dry and fissured tongue; and their convalescence was uninterrupted and rapid. I was not sufficiently impressed at the time with the irrigation method to employ it in all my cases. I treated several cases in accordance with the approved methods of our modern text-books. But it was the same old, old story! They got along just like the cases I had five years ago, just like the cases I had ten years ago. There were the same stupid expression of the facies, the same insomnia, the same delirium, the same nervous twitchings, the same dry, glazed, and cracked tongue. It is therefore my candid opinion that there has been no material improvement in the medicinal treatment of typhoid fever during the last decade, notwithstanding the use of our modern antiseptics and antipyretics.

In regard to the second indication—the employment of an internal antiseptic—probably calomel is our best, yet its continued use is depressing. It may, however, be used with advantage in the initial stages in full doses continued for a few days, and in small doses of from one twentieth to one twelfth of a grain for the first week or ten days. I believe that bismuth in large continued doses fulfills the indication of a non-deleterious internal antiseptic (9). I employ it in every case and continue it throughout the course of the disease.

I have used salol in doses of three to five grains every four hours and sulphocarbolate of zinc in doses of two or three grains. Sometimes I thought I received advantage from one, sometimes from the other, and many times I have been in doubt as to the benefit of either. With the so-called specific treatment, a combination of tincture of iodine and carbolic acid, long ago suggested by Roberts Bartholow (10) and recently revived by a writer in the *New York Medical Journal*, my experience has not been satisfactory.

With thymol, the drug so strongly advocated as the ideal intestinal antiseptic by Frederick P. Henry, my experience has not been sufficient to warrant me in expressing an opinion. Dr. Henry, however, speaks very highly of this drug when he says: "In a word, my experience has convinced me that the typical symptoms of typhoid fever will rarely develop if thymol is administered during the first week of the disease." Dr. Henry employs this drug in doses of two and a half to five grains in pill form every three hours.

Nitrate of silver has been strongly recommended by Dr. William Pepper (11), who reports a hundred consecutive cases without a single death. He begins this treatment early and continues it throughout the course of the disease. His dose is one fifth to one fourth of a grain in pill form. In cases in which I made trial of this drug I failed to note any appreciable benefit. I felt, however, that it might be of benefit during the ulcerative stage if its solubility was not such that it is extremely doubtful that it ever reaches the ulcerative areas to exert its topical action.

I now come to the third and last indication, the dietetic and symptomatic treatment of the disease.

By many the dietetic treatment of typhoid fever is regarded as of the most importance. The diversity among writers as to the amount of food is very great, though nearly all agree as regards kind and quality. Foods readily assimilable, principally digested in the stomach and leaving a small residue, are to be chosen. Milk is the ideal food for the typhoid-fever patient.

Assistant Surgeon R. M. Woodward (12), in his report for 1890, cites nineteen cases of typhoid fever treated almost exclusively by the milk diet. He prescribed nine pints of milk in the twenty-four hours and encouraged his patients to take the full amount. All his cases recovered.

Dr. Henry puts the daily amount of milk at two pints, Osler at three pints, and both urge careful observation daily that these amounts do not cause acute indigestion. My observation has been to the effect that the average adult will assimilate from three to four pints of milk daily. The amount assimilated one day may not be the same as

that of the next. Masses of curds found in the stools suggest overfeeding. Some kinds of milk are too rich in fats and should be skimmed. Beef tea and albumen water may be temporarily substituted.

The principal symptom to combat is pyrexia. Notwithstanding the employment of antipyretics, old and new, the thing I have most faith in is water. From a quart to half a gallon of pure cold water should be given to a typhoid-fever patient each day, whether he asks for it or not. I have never tried the Brand method, yet I believe in it and think a time will come when it will be more universally used. I do the next best thing—I employ the sponge bath. I order my patients sponged and rubbed every hour when the axillary temperature exceeds 102° F. This will promote perspiration, quiet or prevent delirium, and secure peaceful slumber.

Alcohol I use but sparingly, and have not been impressed with its utility in any cases except those that were previously much addicted to drink. Instead, I use strychnine in doses of from one sixtieth to one twentieth of a grain. A very eligible preparation is the elixir of bismuth, pepsin, and strychnine. Quinine I frequently employ in decided doses at the onset of the disease and in tonic doses throughout its course. To assist digestion I use a combination of pepsin and hydrochloric acid. For insomnia and restlessness I have found Dover's powders in six to eight-grain doses to act admirably. For sleeplessness, chloralamid in thirty to forty-grain doses has proved beneficial. For the severe headaches of the first week I feel assured that antipyrine combined with caffeine has proved of advantage. As a routine practice, during the first ten days I give fifteen to twenty grains of antipyrine in divided doses in the evening. It produces free perspiration, quiets delirium, and promotes a good night's rest. If thorough irrigation of the colon be employed at an early period, diarrhœa will not be a troublesome symptom. If excessive, it may be controlled by Dover's powders and bismuth. For other symptoms, such as epistaxis, meteorism, intestinal hæmorrhage, and the various complications that are concomitants or sequels of the disease, a proper consideration of the general principles of medicine will guide one to as successful an issue as may be hoped.

In conclusion, I will state it as my honest conviction that in the treatment of typhoid fever an early and thorough irrigation of the colon, a proper dietary, and a copious internal and external use of water are more to be relied upon than the employment of drugs.

A CASE OF COMPLICATIONS.

By H. ELLIOTT BATES, M. D.,
POUGHKEEPSIE, N. Y.

C. F. G. applied for treatment for a gonorrhœa of four days' duration, the discharge being abundant, purulent, blood-stained, and swarming with gonococci. An alkaline mixture was prescribed, a suspensory bandage adjusted, the patient directed to keep off his feet as much as possible and observe ordinary precautions as to diet and drink, and twenty grains of sodium bromide, with a suppository of opium and aconite, were prescribed to diminish the pronounced chordee. All went well for ten days, when I was sent for to call at his boarding place. The patient had taken a long walk into the country, and, being rather heated, lay down upon the ground for some time. Upon his return to his boarding place he had a violent chill, followed by intense pain, vesical tenesmus, incessant desire to urinate, nausea, and vomiting. Temperature, 104° 5' F.; pulse, 108. Urination was exceedingly painful; the few drops expelled at each attempt consisted of blood and pus. Half a grain of sulphate of morphine hypodermically, an infusion of flaxseed and *Triticum repens* in an alkaline mixture, suppositories of opium, belladonna, and aconite, elevation of the pelvis, and warm poultices applied over the bladder, were ordered. The next morning saw the symptoms of cystitis very much more pronounced. Temperature, 105° F.; pulse, 120, with mild delirium and a scanty purulent bloody discharge. Sulphate of quinine, Dover's powder, and cold sponging reduced the temperature to 102°; the tenesmus diminished. The next morning pain was complained of in the left testicle, and examination revealed a promising epididymitis. Hot poultices of tobacco and hops, suspension, and an anodyne suppository relieved the pain considerably. The temperature remained at 101°. Nourishment, before rejected, was retained. The bowels had been kept open by enemata. The prepuce was long and tight, and, although cautioned against leaving this retracted for any length of time, the patient had neglected it; consequently the condition of paraphimosis was added to the others; the swelling was the size of a closed fist and solidly edematous. Multiple puncture, hot applications, and pressure rapidly reduced the swelling to one third its size, and attention was called to a throbbing pain in the perineum, increase of temperature, pulse, and restlessness. Rectal examination revealed a hot and swollen prostate, which was about to suppurate. Cold to the perinæum, cold rectal injections, and free saline catharsis prevented further trouble from this source. The cystitis began to decline, the epididymis returned to its normal size after inunction with the oleate of mercury, and the patient, after a tedious convalescence, was able to walk to the office, where examination by the sound revealed the existence of two strictures of large caliber—one in the anterior, the other in the membranous urethra. As physical examination of the lungs revealed a few crackles at the left apex, the patient was directed to leave the city for a time, to

have the strictures dilated with the sound, but on no account to submit to a cutting operation. He returned to the city some months later, and said that the physician to whom he applied for treatment "cut the strictures," and the operation was followed by a prompt return of the epididymitis and paraphimosis. He was ordered to discontinue all treatment for a time, and then to have the strictures dilated, as examination showed that they had contracted even beyond the degree at first present. Some time after, he left the city for his home, saying that he felt perfectly well and had no trouble of any kind.

The case, while presenting nothing new, is remarkable for the recovery from so many conditions, any one of which is often treated as a serious condition. It also goes to prove the superiority of the dilatation of recent soft strictures with the sound over the cutting operation, and also that, even after all precautions have been taken, a gonorrhœa may develop into a far more serious condition as the result of any indiscretion. In this case no injections were used, and it is the writer's practice never to employ them in any case until the acute stage has passed and the discharge has become thin and non-purulent. Even then the passage of the sound will often stop the discharge sooner than an injection. The writer has yet to see a stricture result from such treatment in a single case of gonorrhœa, and believes that, in the majority of cases, to the use of an irritating injection, and not to the gonorrhœa itself, may be ascribed the formation of urethral stricture.

18 GARDEN STREET, July 15, 1893.

The Diagnosis of Cholera.—Professor Robert Koch has published in the *Zeitschrift für Hygiene*, Bd. xiv, Heft 2, a communication on the diagnosis of cholera. He refers to the fact that the cholera vibrio is invariably present in cases of Asiatic cholera [a fact that Cunningham and other Indian observers still deny], and says it is not found under other conditions; so it is important that its presence should be easily and rapidly demonstrable. Where means have to be devised to prevent the spread of the disease, and an early diagnosis is essential, some more rapid method is required than that of plate cultures, that is most useful in cases in which the vibrios are present in large numbers and several days are available for the process of development.

Koch found that a rapid microscopic examination of the materials forwarded to him from various parts of Germany enabled him to telegraph, almost immediately in about half the cases examined, whether the patient from whom the dejecta were obtained was affected with cholera or not. A microscopic examination of the mucous threads and flakes shows the cholera vibrios arranged in groups in which the single vibrios run parallel like a shoal of small fish following one another in a stream. This appearance he considers so characteristic of the cholera spirillum that when it is present he does not hesitate to make the diagnosis. Dunham, of New York, suggested a one-per-cent. peptone solution with one half per cent. of sodium chloride as a medium in which the organism would grow, reducing the nitrates to nitrites and also forming indol in its growth, so that on the addition of hydrochloric or sulphuric acid the "red reaction" was readily obtained. Dunham also found that the cholera vibrio grew in this mixture at an enormously greater rate than the other organisms found in the intestinal tract, and, on account of the affinity of the vibrio for oxygen, an almost pure culture may be obtained from the surface of the peptone medium. Koch finds that a one-per-cent. is preferable to a one-half-per-cent. solution of salt; and with this method, Hueppe's method of intraperitoneal injection, and gelatin and agar plate methods he was able to make a rapid and accurate diagnosis in all the cases submitted to him. It requires six hours to obtain the red reaction, and from eight to ten hours for colonies to be recognizable on the plates.

WHITEHEAD'S OPERATION FOR HÆMORRHOIDS.

IN the August number of the *Medical Chronicle* there is an abstract of an interesting and important paper by Professor James Thompson, of the University of Texas, in which the author deals with Whitehead's operation from an anatomical point of view. Concerning the "pile-bearing area," which is completely excised in the operation, he says that, either on the cadaver or on the living subject, one can easily separate the mucous membrane of the lower portion of the rectum from its supporting structures as high as the upper border of the internal sphincter; and this procedure is accompanied by no hæmorrhage, provided the mucous membrane only is lifted from its bed. Around the anal margin the junction of skin and mucous membrane is carefully divided, and a few snips of the scissors soon open a cellular interval between the two sphincter muscles (internal and external) and the mucous membrane. This interval of loose cellular tissue extends above as high as the upper border of the internal sphincter, where it blends with the submucous coat of the rectum, which, being dense, firmly binds the mucous membrane to the circular muscular coat of the gut. At this level a vertical section shows the following relation of structures: The horizontal muscular coat of the bowel ceases abruptly, and is lined on its outer side by a prolongation of the pelvic fascia, which is continuous with that lining the upper surface of the levator ani. The circular muscular coat of the bowel changes abruptly into a thick bundle of fibers called the internal sphincter. This muscle is very strong, and is composed of involuntary fibers. Above and externally it blends with the upper fibers of the levator ani and a prolongation of the pelvic fascia, while below it is overlapped by the upper border of the external sphincter. Above and internally the muscle is firmly attached to the mucous membrane by the submucous coat, which is dense and unyielding, while below the loose cellular tissue above mentioned intervenes between it and the mucous membrane. The internal sphincter is easily brought into view by a clear dissection, and is "seen in all its glory" in a well-conducted Whitehead's operation. The external sphincter is a thin band of voluntary muscular fibers which surrounds the anal margin. It is seen but poorly in the dissecting room, and rarely comes into view during properly conducted operative procedures. Its outer surface receives the insertion of the levator ani and forms the inner boundary of the ischio-rectal fossa; its inner surface above is applied to the outer side of the internal sphincter, while below it forms the outer boundary of the lower part of the connective-tissue space before mentioned. This space, to which Professor Thompson

gives the name "peri-anal," has the following relations: It is about an inch long. Internally it is bounded by the mucous membrane, externally by the two sphincter muscles; above it is closed by the firm cohesion of internal sphincter submucous coat and mucous membrane, below by the union of skin and mucous membrane at the anal margin.

The blood-vessels of the rectum have been specially studied by the author. There is, he says, a particularly complete anastomosis between the portal and systemic system of veins which carry away the blood from the lower end of the rectum—so complete that an injection fills both the pudic and the internal iliac veins. The superior hæmorrhoidal vein carries away the whole of the venous blood from the mucous membrane of the rectum as low down as the anal margin. The vessels form a fine network completely surrounding the rectum; they are arranged in three distinct masses of vertical vessels with cross branches. These masses are situated respectively one on each postero-lateral aspect, and one on the anterior wall of the rectum; and it is in these situations that the anastomosis with the systemic veins is found. That on each postero-lateral aspect unites the superior and inferior hæmorrhoidal trunks. That on the anterior wall unites the superior hæmorrhoidal with the middle hæmorrhoidal and inferior vesical. All these anastomosing trunks pass across the "peri-anal space," and pierce the sphincter muscles to reach the systemic veins. The arteries practically follow the same course as the veins. Above the upper margin of the internal sphincter they lie outside the muscular coats of the gut, and pierce it at varying levels, until, becoming submucous, they course as vertical trunks to the anal margin.

The superior hæmorrhoidal artery passes on each postero-lateral aspect in the above-mentioned clusters of vessels, and, at the anal margin, blends by fine anastomoses with radicles from the inferior hæmorrhoidal artery. The arteries running in the anterior cluster of vessels are derived mainly from the superior hæmorrhoidal, but passing through the upper margins of the internal sphincter are one or two trunks anastomosing with the middle hæmorrhoidal and the inferior vesical vessels. In a dissection the arrangement of the veins in the "pile area" was shown. They were distended with venous blood, and showed very clearly the three clusters or columns on the postero-lateral and anterior walls. The venous distention extended from the anal margin to the upper border of the internal sphincter, where it ceased abruptly. The internal sphincter had been rolled up and one of the anastomosing trunks could be seen piercing it.

In a diagram shown, three large pile masses were seen having postero-lateral and anterior positions respectively. The anterior mass, which is usually of about half the size of the others, corresponds, the author says, to the anterior radicles of the superior hæmorrhoidal vessels and their anastomoses with the middle hæmorrhoidal and inferior vesical. The two postero-lateral masses correspond to the lateral trunks of the superior hæmorrhoidal, and their anastomoses with the inferior hæmorrhoidal. This disposition of parts is almost invariable,

and has been present in all cases that have come under his observation. It may not be clearly seen before complete dilatation of the sphincter; but after dilatation, the prolapse of the pile area will invariably demonstrate this peculiarity. A proper knowledge of this fact is necessary, for in these masses lie the vessels which have to be secured in the later stages of Whitehead's operation.

The anastomosis is complete, the veins have no valves, and, under ordinary circumstances, the greater part of the venous blood passes up the superior hæmorrhoidal vein to the portal system and thence through the liver. If from some cause this natural outlet is obstructed, the blood must find some other channel, which it does by its communications with the vesical and the middle and inferior hæmorrhoidal vessels. These outlets are inadequate to establish a free flow, and, as the superior hæmorrhoidal arteries are still carrying fresh blood into this area, an undue distention must result. Above the margin of the internal sphincter these veins are firmly supported by the dense submucous coat and firmly investing circular muscle, which they soon pierce. Below this point they lie in a comparatively loose cellular layer, which gives them practically no support. In consequence, undue distention results, entailing in its course chronic phlebitis, thrombosis, etc.; in fact, all the phenomena which may accompany varicosities. Of course the existence of this loose cellular space is only a predisposing cause. There is probably some other factor at work in the production of true hæmorrhoids besides mere venous distention. The importance of this loose connective tissue in connection with Whitehead's operation can not be overestimated. It enables the rectum to be safely separated from the surrounding tissues with but trifling hæmorrhage and absolutely no damage to the sphincter muscles.

Professor Thompson then describes Whitehead's operation, and says that in most cases it might be advisable to employ a method, suggested to him by Dr. Sampson, which he has found has a practical bearing on the simplicity and bloodlessness of the operation. After the tube of mucous membrane has been separated from the soft parts, a loop of catgut is thrown around the vessels which pass into the bases of the three main pile masses. It is best passed in the following manner: A needle on a handle is threaded with a doubled loop of catgut; by passing the needle inside the tube, the pile mass is transfixed at its center, the point of the needle projecting into the deep part of the wound. The free folded end of the loop is seized and the needle withdrawn, carrying with it the two free strands. The pile mass is again transfixed a little to one side of the vessels entering it, and one of the free strands of catgut is withdrawn from the eye of the needle and passed under the loop. The needle is now withdrawn, carrying with it the other strand of catgut. The pile mass is again transfixed on the other side of the vessels, the catgut is unthreaded, and the two strands firmly tied. In this way a Staffordshire knot is made, and the two strands emerging from the wound give the operator full control of the mucous membrane after the piles have been snipped away. Sutures are applied, as in Whitehead's method, catgut being employed in preference to silk.

Stress is laid on the necessity of opening the "peri-anal space" in the early stages of the operation. Failure to do this will almost of necessity entail more or less injury to the sphincter muscles, causing at some later date incontinence of fæces. But the author maintains that if the operation is conducted on the lines laid down, and the integrity of the skin is maintained, stricture and incontinence of fæces will never follow the operation. Hæmorrhage, he says, is a mere detail; it is controlled with ease when the operation is conducted by Mr. Whitehead's method, and when the ligature he describes is used the cut surface is absolutely dry.

We have given the substance of Professor Thompson's paper largely in his own words. It is illustrated with very instructive diagrams, and we commend it to our readers.

THE ECONOMY OF SANITATION.

UNDER the heading of *The Pied Piper of Hamelin*, A Sanitary Allegory, the *London Sanitary Record* indulges its readers in a comparison between the subject of Browning's delightful poem and those municipal governments that are niggardly in dealing with sanitary questions. The story should be better known than it is. It was about five hundred years ago, according to Browning, that a pest of rats infested the town of Hamelin in Brunswick. The mayor and aldermen were at their wits' end to get rid of the rodents, when the "pied Piper" came along and engaged to free the town for the sum of a thousand guilders. As the story goes, he played upon his pipe so cunningly and alluringly that all the rats, save one, followed him to the river Weser, and thus ended the plague of the rats. Great joy was felt throughout the city, and naturally the piper expected a prompt payment of his well-earned guilders. But the mayor and corporation grew stingy; "their troubles were over, they thought, and they would be troubled no more; but to get rid of the pestilent fellow, they offered him fifty. Then comes the tragedy of the story. They had treated their deliverer shabbily; they had put him in a passion, and they found him pipe to another fashion. Again he piped, so sweetly and persuasively, that all the children in the town came flocking out, and ran merrily after the wonderful music with shouting and laughter; and they followed their leader to the side of a mountain, which opened and swallowed them all up, and they were never heard of more—in Hamelin; and the parents in that ill-fated city were left to mourn.

"But it isn't true? We are not so sure of that. It is certainly in print; and if it weren't true, how could a grave poet like Robert Browning have taken the trouble to write out the story in charming verse? For our part we believe it to be perfectly true—if not in the letter, certainly in the spirit. When Browning wrote it, do you not think he had in view those principalities that grudge the expense of paying to get rid of nuisances? There are plenty among ourselves who still act the part of the mayor and corporation of Hamelin. Clearly the meaning of the poem is that if you are mean enough to grudge the necessary expenditure for ridding your town of destructive pests,

then you will have to pay for your sordid economy in the loss of your dearest. *You will see your children pass away before your eyes, and you will be utterly unable to stop them or to recall them. You will have to pay the piper* somehow; if not in money, then in some far more costly and tragical fashion. Bacilli are more troublesome and more destructive than even rats, because they destroy the most valuable of all property, and they can not easily be got rid of without spending money. Disease is the costliest of all conditions for a town, while the expenditure on sanitation is the wisest economy."

The poet Browning can hardly be held responsible for the lesson drawn by the editor of the *Record*, for the instruction of parsimonious health boards, but we find the parable so apt and pertinent that we have ourselves ventured to italicize the sentences that point out the almost inevitable loss of the lives of infants. It is the family circle that is rent at its weakest, yet its dearest, point. Thus it is that the innocent citizen "pays the piper" when economy in public-health matters overrules other considerations.

CHLOROMA IN ITS RELATIONS TO LEUCÆMIA.

DR. GEORGE DOCK reports in the *American Journal of the Medical Sciences* for August a new case, the seventeenth on record, of this rare disease. The title of his paper is Chloroma and its Relations to Leucæmia. The salient feature of this disease is the green color of the morbid growths found in various structures, which color has given rise to the names chloroma, green cancer, and cancer vert. In Dr. Dock's case the prevailing color may be described as pea-green. In some situations, however, the hue was a pale sage-green, in others darker, and in others there were pink, red, or brown stains. There were small growths in the liver and kidneys that were almost white, but in the pancreas and in the thymus the color was a pale green. The color gradually faded from the specimens that were removed and preserved in solutions. The pigment producing the green color is not yet known, but it is dissimilar to the coloring matters of the bile and the blood.

In all cases some part of the head has been found to be the seat of the morbid growth. The periosteum of the vertebrae and of the ribs adjoining is affected. The predilection of the green substance for the periosteum, especially that of the cranium, has been repeatedly remarked, and many observers incline to regard the periosteum of the skull as the starting point of the disease.

The disease is most frequent in early life. Its course is a short one. Twelve cases showed an average duration of five months. The patient shows marked anæmia without known cause, emaciation, loss of muscular power, rapid pulse, and dyspnoea. Among the other symptoms have been reported epistaxis, various hemorrhages, disturbances of vision, strabismus, exophthalmia, tinnitus, and deafness. Tumors are found under the temporal muscles, or on the cranium in other parts, or on other bones. Before the recognition of these tumors, the diagnosis will be doubtful, but after the appearance of tumors in the orbit and under the temporals, the nature of the case becomes

plain almost to certainty. The blood should be examined to determine if the leucocytes are increased or altered, and, that not being detected, an examination should be made from time to time in order to ascertain the possible occurrence of leucæmia, which may come on only a short time before death. The liver, spleen, lymphatic glands, and bones should be examined as to their contour, size, and tenderness. The new growths may be classed as sarcomatous, in that they contain connective-tissue formations with an excessive development of the cellular elements.

The fact that three cases have been reported from Prague, an equal number from Glasgow, and two from Paris is a point that may deserve attention, although without appreciable significance at the present time.

THE PAN-AMERICAN MEDICAL CONGRESS.

We would urge upon those of our readers who can in any way arrange their engagements so as to allow of their visiting Washington next week that they attend the Pan-American Medical Congress to be held there at that time. The postponement of the International Medical Congress that was to have been held in Rome this month, at such an interval after the Pan-American as to admit of attendance upon both, may operate to discourage a few from going to Washington, but it ought not to have that effect—indeed, as the *British Medical Journal* suggests, the Pan-American Medical Congress may well be taken as a substitute for the International.

The programmes that we have published from time to time give ample evidence of the importance of the topics that will come up for discussion and of the character of the men who are to deal with them. Indeed, we do not recall similar announcements that have been of greater promise. And this is not true merely of certain sections; it may be taken as applying to them in general. The proportion of theoretical to practical papers is such as to satisfy the most discriminating in the medical profession, also that of the readers from the various countries that are to take part. In short, all the indications are that the congress will be an event worthy of the medical profession of the hemisphere.

MINOR PARAGRAPHS.

THE EUCALYPTUS AND THE MOSQUITO.

A CORRESPONDENT of *Insect Life*, who is the owner of one of the largest and oldest groves of *Eucalyptus globulus* in his part of California, says that for fifteen years he has had opportunities to observe those trees as repellants of insects. Over thirty years ago his attention was first called to the subject by a physician who had resided in Australia for some years. That physician assured him that the mosquito, so troublesome to Californians, was unknown in the Australian eucalyptus forests and swamps, but added there's a "spotted mosquito" nearly as bad there in some places. He, not being an entomologist, was unable to tell whether the "spotted mosquito" was a species of the genus *Culex*, or of some allied genus. The physician was evidently a good, close observer, and the writer considered it

worth his while to take the hint. He adds: "I determined to test the anti-mosquito qualities of the eucalyptus, so when I began to improve my house here nineteen years ago, one of the first things I did was to get a lot of eucalyptus seed from Australia and plant out a grove of the trees. The tallest of them are now over one hundred and forty feet tall, and can be seen for twenty miles around. My house stands in the midst of these trees. My irrigating ditch, a dozen feet wide, of sluggish current, runs through the grove beside the house. There has never a single mosquito larva been seen in this ditch from where it enters the first shade of these trees to where it emerges from them two hundred yards away; while above and below mosquito larvæ are plentiful—not immediately below, but some hundreds of yards away, where the water stands in pools and becomes stagnant among a growth of black walnuts and cotton-woods. My live stock pasture in this timber, going into the walnuts and back again under the eucalyptus shade at pleasure. Frequently when the cows come up at night they bring a swarm of mosquitoes; occasionally some of them get into the house, but cause us so little annoyance that we scarcely notice them. Before this ditch reaches the eucalypti it runs through a jungle of 'fence bamboo,' where the mosquitoes are so bad that we avoid working there except on the windiest days. And, though the ditch has more currents there, the larvæ of mosquitoes are plentiful in the water till it reaches the eucalyptus trees, below which point none are found, till it has become stagnant away below them."

THE TÆNIA TUBÆ.

DR. F. BYRON ROBINSON, of Chicago, gives a description of a band in relation with the peritonæum covering the Falloppian tube not heretofore noticed in the works on anatomy. He describes the band as a thickening of the upper border of the perisalpinx or peritonæum covering the upper border of the tube. He names it the *tænia tubæ*. The colon of man has three bands running from the cæcum to the rectum. These bands are shorter than the colon and hence sacculate the colon and change its direction. This *tænia tubæ* is similar. It lies both in the peritonæum and on the musculature of the tube. He has noticed this tubal band quite a number of times in examining large numbers of tubes. It is significant as it aids in sacculating the tube. The sacculating of the tube is detrimental to the facility of transmitting ova, as the shortening of the tube causes kinks, angles, and convolutions in the tubal lumen which will retard the passage of an ovum through the tube to the uterus. These severe sacculations also give occasion to ectopic gestation by allowing the ovum to slip into portions of the tube which are not in the main stream of menstrual fluid, induce supersecretion of the tubal mucous membrane, by cilia flapping toward the uterus, and tubal peristalsis. The women possessing this band (*tænia tubæ*) have usually premenstrual pain or tubal colic on account of the difficulty of forcing fluids through a convoluted tube. So far as has been observed, such women either are sterile or have few children. This band is no doubt a relic of embryonic life or a relic of the Wolffian body. Such tubes have a slight congenital appearance. They are short, small, and spiral. The best way to see the band well is to put in pure alcohol some decidedly spiral, convoluted, or contorted tubes. After the tubes have been in the alcohol some time, the band (*tænia tubæ*) shortens much more than the tubes, and the band becomes plain and thick. Under a powerful lens the band appears to be composed chiefly of connective tissue, though no microscopical examination has been carried out. This band is often very distinct in certain tubes,

and it is easy of observation, for generally the Falloppian tube is entirely loose in the broad ligament. The peritonæum does not even dip down into the tubal kinks, whereas in the specimens with the *tænia tubæ* the tube is fixed in relation with the band.

THE NEW YORK PHYSICIANS' MUTUAL AID ASSOCIATION.

WE take great pleasure in being able to announce that the association has just given notice of a prepaid assessment to all its members in good standing. The membership is now over 1,200 and steadily increasing.

ITEMS, ETC.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending August 22, 1893:

DISEASES.	Week ending Aug. 22.		Week ending Aug. 23.	
	Cases.	Deaths.	Cases.	Deaths.
Typhus.....	0	0	0	0
Typhoid fever.....	30	4	37	8
Scarlet fever.....	34	4	34	2

Small-pox.....	1	1	2	0

The Medical Corps of the Army.—An army medical board will be in session at Washington City, D. C., during October, 1893, for the examination of candidates for appointment to the medical corps of the United States Army, to fill existing vacancies. Persons desiring to present themselves for examination by the board will make application to the Secretary of War, before September 15, 1893, for the necessary invitation, stating the date and place of birth, the place and State of permanent residence, the fact of American citizenship, the name of the medical college from whence they were graduated, and a record of service in hospital, if any, from the authorities thereof. The application should be accompanied by certificates based on personal knowledge, from at least two physicians of repute, as to professional standing, character, and moral habits. The candidate must be between twenty-two and twenty-eight years of age and a graduate from a regular medical college, as evidence of which his diploma must be submitted to the board. Further information regarding the examinations may be obtained by addressing the Surgeon General, U. S. Army, Washington, D. C.

The medical corps of the army consists of a surgeon general with the rank of brigadier general, six assistant surgeons general with the rank of colonel, ten deputy surgeons general with the rank of lieutenant colonel, fifty surgeons with the rank of major, and one hundred and twenty-five assistant surgeons with the rank of first lieutenant, mounted, for the first five years and the rank of captain, mounted, thereafter until promoted to major. Promotion through the intermediate grades of rank from that of captain to that of colonel is by seniority, but there is an examination for the rank of captain and another for that of major, to ascertain the fitness of the officer for promotion. Advancement to lieutenant colonel and colonel takes place without further examination. The surgeon general is selected by the President from among the members of the corps. All vacancies are filled by appointment to the junior grade.

To each rank is attached a fixed annual salary, which is received in monthly payments, and this is increased by ten per cent. for each period of five years' service until a maximum of forty per cent. is reached. An assistant surgeon with the rank of first lieutenant, mounted, receives \$1,600 per annum, or \$133.33 monthly. At the end of five years he is promoted to captain and receives \$2,000 a year, which, with the increase of ten per cent. for five years' service, is \$2,200, or \$183.33 per month. After ten years' service he receives \$2,400, after fifteen years

\$2,600, and if he remains a captain after twenty years, \$2,800 per year. The pay attached to the rank of major is \$2,600 a year, which, with ten per cent. added for each five years' service, becomes \$3,250 after fifteen years and \$3,500 after twenty years. The monthly pay of lieutenant colonel, colonel, and brigadier general is \$333.33, \$375, and \$458.33 respectively. Officers in addition to their pay proper are furnished with a liberal allowance of quarters according to rank, either in kind, or, where no suitable Government building is available, by commutation. When traveling on duty an officer receives four cents per mile and reimbursement of money actually expended for railroad or other fares. On change of station he is entitled to transportation for professional books and papers and a reasonable amount of baggage at Government expense. Mounted officers, including all officers of the medical corps, are provided with forage, stabling, and transportation for horses owned and actually kept by them, not exceeding two for all ranks below a brigadier. Groceries and other articles may be purchased from the commissary and fuel from the Quartermaster's Department at about wholesale cost price. Books and instruments are supplied in abundance for the use of medical officers in the performance of their duties.

By a recent order the Secretary of War has authorized the establishment of an Army Medical School in the city of Washington for the purpose of instructing approved candidates for admission to the medical corps of the army in their duties as medical officers.

The course of instruction will be for four months, and will be given annually at the Army Medical Museum, in Washington City, commencing on the 1st day of November.

Four professors will be selected from among the senior medical officers of the army stationed in or near the city of Washington, and as many associate professors as may be required to give practical laboratory instruction in the methods of sanitary analyses, microscopical technique, clinical microscopy, bacteriology, urine analysis, etc.

The faculty of the Army Medical School will consist of—

1. A *president of the faculty*, who shall be responsible for the discipline of the school, and who will deliver a course of lectures upon the duties of medical officers in war and peace (including property responsibility, examination of recruits, certificates of disability, reports, rights and privileges, customs of service, etc.).

2. A *professor of military surgery* (including the care and transportation of wounded).

3. A *professor of military hygiene* (including practical instruction in the examination of air, water, food, and clothing from a sanitary point of view).

4. A *professor of clinical and sanitary microscopy* (including bacteriology and urology).

A medical officer after completing the course of instruction at the Army Medical School will be assigned for some months as junior at a large military post in order that he may become acquainted with army regulations, the making of official reports, and other matters necessarily new to him, before he is thrown upon his own responsibility. His stations after that are likely to alternate between the frontier and more desirable points, a tour of duty being usually four years at one place. Leave of absence on full pay is allowed at the rate of one month per year, and this when not taken may accumulate to a maximum of four months, which at the end of four years is then available as one continuous leave. Beyond this an officer may still be absent with permission on half pay.

It is the intention of the surgeon general to recommend the assignment for duty, as attending surgeons in the principal medical centers of the United States, of medical officers who have not yet passed their examinations for promotion to a majority, and, so far as may be practicable, in the order of their seniority. These details will be made for one year only, in order that as many medical officers as possible may be enabled to avail themselves of the opportunities thus offered to become familiar with the practice of the leading physicians and surgeons in this country, and of attending medical lectures, meetings of medical societies, etc. At the end of this tour of duty medical officers will be required to make a detailed report to the surgeon general showing how much of their time has been occupied by their official duties and to

what extent they have availed themselves of the advantages offered for professional advancement.

Absence from duty on account of sickness involves no loss of pay. Medical officers are entitled to the privilege of retirement at any time for disability incurred in the line of duty or after forty years' service. On attaining the age of sixty-four they are placed upon the retired list by virtue of statutory provision. Retired officers receive three fourths the amount of their pay proper at the time of retirement.

Appointments to the medical corps of the army are made by the President after the applicant has passed a successful examination before the Army Medical Examining Board and has been recommended by the surgeon general. The board usually meets twice a year, about April and October, of which due notice is given by advertisement. Permission to appear before the board is obtained by letter to the Secretary of War, which must be in the handwriting of the applicant, giving the date and place of his birth and the place and State of which he is a permanent resident, and inclosing certificates based on personal acquaintance from at least two reputable persons as to his citizenship, character, and habits. The candidate must be a citizen of the United States, between twenty-two and twenty-eight years old, of sound health and good character, and a graduate of some regular medical college, in evidence of which his diploma will be submitted to the board. The scope of the examination will include the morals, habits, physical and mental qualifications of the candidate, and his general aptitude for service; and the board will report unfavorably should it have a reasonable doubt of his efficiency in any of these particulars.

The physical examination comes first in order, and must be thorough. Each candidate will in addition be required to certify "that he labors under no mental or physical infirmity or disability of any kind which can in any way interfere with the most efficient discharge of any duty which may be required." Errors of refraction, when not excessive and not accompanied by ocular disease, and when correctible by appropriate glasses, are not causes for rejection.

The mental examinations are conducted by both written and oral questions, to which written and oral answers are required upon—

- I. Elementary branches of common-school education, including English grammar, arithmetic, the history and geography of the United States, natural philosophy, the principles of Latin grammar, and upon general literature and ancient and modern history. Candidates professing special knowledge of the higher mathematics, ancient or modern languages, drawing, analytical chemistry, or other branches of natural science, will be examined in those matters as accomplishments, and will receive due credit therefor according to their proficiency.

- II. Professional branches, including anatomy, physiology, chemistry, hygiene, pathology and bacteriology, therapeutics and materia medica, surgery, practice of medicine, obstetrics, and the diseases of women and children.

Examinations at the bedside will also be conducted in clinical medicine and surgery, and operations and demonstrations upon the cadaver.

Hospital training and practical experience in the practice of medicine, surgery, and obstetrics are of great importance to candidates seeking admission to the medical corps of the army, and they will be fully appreciated and duly credited to those who have had such advantages.

The board has discretion to deviate in such manner as it deems best from this general plan of examination when necessary for the interests of the service.

To save unnecessary expense to candidates, those who desire it may have a preliminary physical examination and a mental examination in the "elementary branches of a common-school education" by a medical officer of the army stationed most conveniently for this purpose, who will act under instructions from the medical examining board.

The merits of the candidates in each of the several branches, and also their relative merit as evinced by the results obtained from the entire examination, will be reported by the board, and, in accordance with this report, approved candidates will be appointed to existing vacancies, or to such as may occur within two years thereafter. An applicant failing in one examination may be allowed a second after one

year, but not a third. No concession will be made for the expenses of persons undergoing examination, but those who receive appointments will be entitled to traveling allowances in obeying the first order assigning them to duty.

There are at present six vacancies in the corps to be filled.

To illustrate the general character of written questions submitted to candidates under examination, a few examples from the records of an army medical examining board recently convened in the city of New York are hereto appended:

Arithmetic.—1. Find the interest on \$400.00 for 2 years, 5 months, and 25 days at 8 per cent. per annum. 2. Find the depth of a reservoir 12 feet square from which 336 cubic yards of earth has been removed. 3. How many grains are there in 184 milligrammes? 4. What is $\frac{1}{2}$ carried to four decimal places? 5. What is $3\frac{1}{2} \times 15\frac{1}{2} + \frac{2}{3\frac{1}{2}} \div \frac{2}{3}$? 6. The shadow of a church tower extends 57 yards; what is the height of the tower when the shadow of a 2-foot rule in a vertical position extends 2 feet 9 inches?

Geography.—1. Which of the United States are bounded in part by the Atlantic Ocean? 2. What are the principal mountain ranges in the western part of the United States? 3. What rivers of North America flow into the Pacific Ocean? 4. Bound the States of Michigan and New Hampshire. 5. Over what waters would a vessel pass in sailing from Washington to Sebastopol, by the shortest route? 6. When it is 12 o'clock noon, standard time, in New York city, what is the standard time in San Francisco? Describe the system of "time belts" in the United States.

History and Literature.—1. Which were the two first permanent English colonies in North America? When, where, and by whom were they established? 2. Name the thirteen original States of the Union in the order in which they were settled. 3. What were the principal causes that led to the Revolutionary War in this country? 4. What poems have especially distinguished the following poets: Virgil, Milton, Young, Gray, James Thomson, and Goethe? 5. Under what Roman emperor was the capital of the empire removed from Rome, and what city became the new capital? 6. Name the principal battles fought in the Persian invasion of Greece by Xerxes. 7. Name the kings and queens of England embraced in the line of Tudor.

Chemistry.—1. State the "law of multiple proportions." When was it discovered? 2. Give the symbols and atomic weights of the bivalent, non-metallic elements. 3. What are the physical and chemical properties of the element represented by the symbol Sb, and by what tests may it be recognized? 4. What do you understand by the following formula: $\text{Fe}_2\text{S}_3\text{O}_4 + 6\text{NH}_4\text{HO} = 3[(\text{NH}_4)_2\text{SO}_4] + \text{Fe}_2\text{HO}$? 5. What is the formula for ethyl ether, and how is it prepared? 6. What substance is represented by the formula $\text{C}_6\text{H}_{12}\text{O}_6$? Where is it found in nature, what are its physical characters, and by what chemical tests may it be recognized?

Physics.—1. What is weight? Is the weight of a body constant? If not, why does it vary? 2. What is osmosis? What conditions are necessary to osmotic action? Give an illustration from the human body. 3. How is dew formed? What circumstances influence its formation? What is meant by the dew point? 4. Upon what fundamental laws of light does the action of lenses depend? Why does a convex lens magnify? 5. What is the velocity of sound? Does it vary, and how? 6. What is the relation between the dynamo and the electric motor? What is the principle of the dynamo?

Anatomy.—1. Give the anatomy of the fourth ventricle, including the origin of nerves. 2. Give the anatomy of the coracoid process. 3. Make a diagrammatic sketch showing the relation of parts in a cross-section [through the middle third of the right arm, proximal surface. 4. Describe the internal pudic artery and its relations. 5. Give a short description of the minute structural anatomy of the kidney, with or without schematic diagram.

Physiology.—1. Tell what you know about the cerebral localization of the functions of motion and locate some of the so-called motor areas. 2. What are the functions of the thyroid gland and the consequences of its removal? 3. What is the composition of atmospheric air and of expired air? 4. Give a list and a short description of some of the

animal albuminoids. 5. What is urea? What is the normal quantity in proportion to body weight? How is it estimated?

Surgery.—1. Give in detail the preparatory and several following steps of a so-called aseptic surgical operation. 2. What is the nature and origin of pus? What is sepsis and also antiseptics? 3. Describe Chopart's amputation through the foot, with diagram. 4. Give the points of diagnostic differentiation in cases of lupus ulceration, syphilitic ulceration, and epitheliomatous ulceration. 5. Describe the different methods of procedure for the reduction of luxations of the head of the femur.

Hygiene.—1. What is the normal amount of CO_2 in the atmosphere, how much of this gas is considered admissible in inhabited apartments, and how is the amount determined? 2. What amount of cubic-air space per bed would you consider a suitable allowance in a hospital ward? 3. What substances in well or river water indicate, by their presence, contamination from excreta or other organic matter of animal origin? 4. How is the hardness of water estimated and to what is it due? 5. What are the constituent alimentary substances in milk, and how does cow's milk differ from human milk? 6. What vegetable products used as food contain the largest proportion of carbohydrates and what the largest proportion of proteids? 7. What parasites dangerous to man may be present in the flesh of animals used as food? 8. How would you disinfect the excreta of patients sick with cholera or typhoid fever?

Pathology and Bacteriology.—1. What are the different stages of exudative inflammation and what the products of such inflammation? 2. What are the causes of thrombosis, what the composition and varieties of thrombi, and what changes may they undergo? 3. What pathological changes are found in the spinal cord in posterior spinal sclerosis? 4. What changes occur in the liver as a result of chronic interstitial hepatitis? 5. What bacteria are commonly found attached to the diseased valves in mycotic endocarditis? 6. What are the morphological and biological characters of the bacillus of diphtheria, and what are the evidences of its etiological relation to this disease?

Therapeutics, Materia Medica, and Toxicology.—1. By what various agents may antipyresis be produced? Give an example of each class of antipyretics and state how it acts. 2. In a case of typical acute pleurisy state the indications for treatment in its several stages and how you would meet them. 3. What is salol? Give its physiological action and therapeutic uses. 4. Give the source and therapeutic uses of cocaine, the dose in each case, and its dangerous effects. 5. With what condition is poisoning from opium most likely to be confounded? How would you make a diagnosis and how treat such a case? 6. What are the poisonous effects of the lead salts? How is their presence detected? State briefly your plan of treatment.

Practice of Medicine.—1. Give an account of the etiology, symptoms, physical signs, and differential diagnosis of lobular pneumonia. 2. Give an account of the etiology, physical signs, and treatment of empyema. 3. Give an account of the etiology, symptoms, differential diagnosis, and treatment of dilatation of the stomach. 4. What are the causes and symptoms of intestinal obstruction and what is the treatment? 5. What are the causes and results of mitral stenosis and how would you recognize this condition? 6. Give the differential diagnosis between small-pox and measles.

Obstetrics and Diseases of Women and Children.—1. Describe briefly the usual mechanism of a breech presentation; what dangers are to be guarded against and what difficulties to be met? 2. Under what circumstances is premature delivery demanded and how would you perform it? 3. What symptoms would lead you to suspect the presence of a uterine fibroid? State how an exact diagnosis can be made in such cases. 4. What measures preventive or remedial would you use in a case of puerperal convulsions? 5. What early symptoms indicate probable onset of the chief eruptive fevers in children? In which does temperature range highest, which has the shortest period of incubation, of invasion, of eruption?

The Buffalo Academy of Medicine.—At the next meeting of the Surgical Section, on Tuesday, the 5th inst., Dr. Eugene Smith is to read a paper on Minor Surgical Operations, and Dr. Frank J. Thornbury is to read one on The Preparation of Suture Material and Dressings.

Mr. Ernest Hart.—The July number of the *Alienist and Neurologist* contains a biographical sketch of Mr. Hart, substantially as follows:

Mr. Hart was born in June, 1836, and educated at the City of London School, where he became captain and Lambert Jones scholar at a very early age. Subsequently he entered St. George's Hospital School of Medicine, where he attained first prize in every class.

At the age of twenty-eight he became ophthalmic surgeon to St. Mary's Hospital School, and held that post for ten years, publishing from time to time papers on ophthalmic subjects, and contributing to the *Moorfields Hospital Ophthalmic Reports* a paper On the Minute Anatomy of the Nerves and Iris, and the Ciliary Body, in which, for the first time, the ganglionic network of the nerves, which lies upon the iris, was described and figured. He introduced into ophthalmic practice medicated gelatin discs.

Mr. Hart projected a commission of inquiry into the London workhouse infirmaries and the treatment of the sick poor, and reported on the subject in conjunction with Mr. Anstie and Dr. Carr. In those days, as then appeared, no special arrangements were made for persons dangerously ill, but they were intrusted to the tender mercies of the pauper nurses, altogether incompetent, whose remuneration for their work was an extra allowance of beer. The result was that a meeting, called at Willis's Rooms, formed a deputation, headed by Mr. Hart, to the Government; the Duke of Westminster, the Archbishop of York, Mr. Maurice, Mr. Hughes, and Dr. Anstie joined a committee which met weekly at his house. A bill was drafted and subsequently Mr. Hardy's act was passed embodying their chief proposals and constituting the Metropolitan Asylums Board, which has charge of the hospitals for sick poor, where they may be properly tended and cared for. The duke and his friends instituted a public subscription for a testimonial to Mr. Hart, and some hundreds of pounds were speedily collected; but Mr. Hart expressed a wish that the matter be dropped.

Another good work which Mr. Hart successfully prosecuted was his exposure of the iniquities of baby farming and other kindred evils. As a result, the Infant Life Protection Act, which he assisted to draft, became law.

Mr. Hart has long been an active member, as well as chairman, of the Parliamentary Bills Committee of the British Medical Association, and in that capacity has done much valuable work. In 1864, when the Government introduced a bill to enable the Secretary of State for India to dispense with competitive examinations and to substitute for them a system of patronage in the Indian Medical Service, the association properly regarded the proposal as derogatory to the honor and interest of the profession, and Mr. Hart led the opposition to it. Mr. Pope Hennessey, M. P., who took strong ground upon the question, read in the House of Commons a memorandum with which Mr. Hart had furnished him, and the bill was defeated upon the third reading.

In the year 1866 Mr. Hart was appointed by the council of the British Medical Association to the editorship of the *British Medical Journal*, an office he still holds, along with the editorship of the *London Medical Record* and the *Sanitary Record*. When he took up the editorship of the *British Medical Journal* it was not a lucrative adjunct of the association; now its profits amount to £6,000 per annum, while the number of members of the association has increased from 2,000 to more than 13,000.

From that time forward Mr. Hart has led a busy life, not only in his editorial work but in promoting in many ways the welfare of the medical profession. Having, in 1867, been apprised that the Lords of the Admiralty proposed to establish a system of bounties to needy medical students in the schools—granting to those who would bind themselves for ten years' naval service a free bounty of £100 in their fourth year at school—he forthwith organized an opposition to the scheme, which was universally considered derogatory to the honor of the profession, and calculated to interfere with its independence; and the official minute and circular were withdrawn in consequence. Again, in 1874, Mr. Hart, as chairman of the Parliamentary Bills Committee of the British Medical Association, prepared a statement, which he submitted to the First Lord of the Admiralty, drawing attention to the medical service of the royal navy, and making proposals for the removal of certain grievances. It happened that the Admiralty had the subject under consideration at the time, and in the next year several concessions

which the committee had suggested as to rank, pay, and retirement were made.

We find that Mr. Hart has not been less energetic for the Army Medical Service, for which he has procured several concessions. About the year 1872 the War Office proposed to make changes much to the advantage of militia surgeons which the Parliamentary Bills Committee stoutly opposed, and the Army Warrant of 1873, chiefly owing to his instance, was so modified as to restore to the medical officers of the army certain privileges of which they had been deprived. At that time the Army Medical Department was unpopular with the profession, and Mr. Hart, as chairman of the committee, therefore presented various reports to the War Office, and was instrumental in drawing attention to the requirements of the service in the matter of pay, retirement, and relative rank. A complete scheme for the reorganization of the service was published in the *British Medical Journal* for January 1, 1879. Ultimately, early in the year 1880, a new Army Medical Warrant was issued, embodying the chief points recommended by the committee, and greatly improving the emoluments of army surgeons, and it had the effect of increasing the number of candidates for the Army Medical Service. Later in the same year Mr. Hart was concerned in the representation to the Government as to the grievances of the medical officers of the Indian Army Service, which was acknowledged to have been successful and valuable.

Following up this result, Mr. Hart at once set afoot inquiries as to the causes of the extreme unpopularity of the Naval Medical Service, and a scheme which he prepared for its amelioration—wherein, among other things, he proposed that the pay of naval candidates at Netley should be equalized with that of candidates of the army—was presented to the Lords of the Admiralty, who issued a new Medical Navy Warrant generally embodying its proposals. "The warrant," said the *British Medical Journal*, "is in a large measure the issue of our own efforts for the good of the service, and is based upon the memorandum of claims drawn up by Mr. Hart, and submitted by him at official request to the First Lord of the Admiralty, by whom it was referred to a Departmental Committee."

Mr. Hart, in 1876, was mainly concerned in organizing an association for establishing coffee taverns in London, which should be self-supporting, the object being to check intemperance. He likewise assisted in forming centers for cheap musical entertainments in poor districts, the Popular Ballad Committee being formed, and the Victoria Theater being formed into a coffee tavern and temperance music hall. Popular concerts are now given in various parts of London, and the Ballad Committee is engaged in training men and women in vocal and instrumental music. Again Mr. Hart sought to improve the condition of London by organizing the Smoke Abatement Movement, and it was chiefly due to him that the Smoke Abatement Exhibition was held in 1882, from which many practical benefits have followed. He is now chairman of the council of the Smoke Abatement Institute. He has also been greatly concerned in the good work of the National Health Society and of the Metropolitan Public Garden and Boulevard Association, of which he is vice-chairman. Of the International Health Exhibition of 1885 he was the projector, and an active member of the executive committee.

In building up the great organization of the British Medical Association Mr. Hart has had a large share, and by its means he has been enabled to do much good work, as has already been seen. From his demonstrations of the truths about vaccination, and his organization of the London Conference on Animal Vaccination, great public good has followed. He has also done good service by organizing a scheme of scientific sanitation of the milk supply of the Metropolis. He has held the office of president of the Harveian and Quekett Microscopical Societies.

In professional questions generally Mr. Hart has always taken the side of the "rank and file." He led the movement for restoring to the medical profession the "Lost School at Oxford," with its rich endowments. He did much to obtain direct representation of the profession in the General Medicine Council, and was nominated, but declined to serve, as a representative on that body. He has from the first warmly supported the claims of women to medical practice and has supplied the funds for two scholarships at the Medical School for Women.

In April, 1893, a meeting was held at Grosvenor House, by the permission of the Duke of Westminster, at which five hundred gentlemen assembled to take part in the presentation to Mrs. Ernest Hart of a portrait of her husband. The Duke of Westminster was to have presided, but, he being suddenly summoned to the House of Lords, his place was filled by Mr. (now Sir Spencer) Wells, then president of the Royal College of Surgeons. Among the speakers were Sir Henry Thompson, Sir F. Pollock, Sir T. W. Charley, Dr. Cameron, M. P., Dr. Farquharson, M. P., Dr. Quain, and others. The address was an epitome of Mr. Hart's life-labors. The portrait was painted by Mr. Frank Holl, R. A., and is admitted by all who have seen it to be an admirable work of art, faithfully conveying the dark, keen, intelligent, well-cut features of the subject, and his small, wiry frame.

In 1884 Mr. Hart began seriously to study the question of founding a society which should afford to medical men the means of providing for their families in the event of sickness and disablement in practice, as well as of death. The medical profession has several charitable societies to relieve the sufferings and alleviate the calamities of disastrous sickness or failure; but, although more than one effort had been made, it had before been found impossible to provide an annuity and sickness fund such as those which the friendly societies supply for the working classes. The society established many years before for this purpose had not met with any success and was quickly dissolved. After studying all the conditions, and obtaining preliminary replies to a circular which was extensively issued with a view of ascertaining a basis of vital statistics for the medical profession, Mr. Hart called a meeting of the profession at the annual gathering of the British Medical Association at Liverpool, and explained his proposed method of proceeding and the organization which he had planned. These proposals were unanimously accepted by the meeting, and the society was founded under his presidency, Sir T. Spencer Wells, Dr. W. M. Ord, and Dr. J. R. Upton acting with him as first trustees, and the executive and general committees being nominated. This society has since greatly prospered, so that at the present moment—three years and a half after its foundation—it has nine hundred members. It has accumulated reserve funds amounting to £20,000, and is paying £40 a week in sick pay to members temporarily or permanently disabled. The basis of success has been secured mainly by great economy in management and by relying fully upon the principle of mutual association without payments to directors, or payment of commissions to agents. The working expenses of the society do not amount to more than five per cent. of its premium income. This is the first society of the kind which has ever been successfully established among the professional classes.

Tramps and Infection.—In an editorial article with this title the *British Medical Journal* for August 19th says: "The interesting discussion at the Newcastle meeting on the spread of infectious diseases by tramps opened up a question which is of the gravest importance to the community. The efforts of sanitarians in regard to the suppression of infectious diseases are at the present day mainly directed into two channels: one the production of such a general improvement of the sanitary surroundings of the people as shall render them more able to resist disease, the other the prompt removal and isolation of the sick, so as to prevent infection of the healthy. Some of the younger and more hopeful among us may think to see the day when the first of these shall be sufficient, but certainly at the present time, and so long as the lives of the poor remain as they are, we can no more afford to allow the free dissemination of infection than a farmer can permit the use of matches in his rickyard.

"Everywhere this is being recognized. Notification is spreading over the land, isolation hospitals are arising on all sides, which, although often very imperfect, show at least that the principle is being widely accepted, by elected and directly responsible bodies, that individuals shall not be allowed to infect the community. As a consequence, respectable citizens are finding their liberties in many respects curtailed, workmen are debarred from their ordinary means of earning a livelihood, children are shut out from an education which is their right, and ratepayers have to support large hospitals, all for the sake of restraining the spread of disease, and yet the vagrant is allowed to roam over the country caring for none of these things, and carrying with him

his rags and his infections from town to town, without let or hindrance. We need, then, feel no surprise that people who have to submit to such restrictions, and who do submit to them with more or less willingness in the hope of thereby deriving some protection, object strongly to their efforts being antagonized by the wanderings of tramps and vagrants.

"The sturdy beggar and the homeless vagrant have troubled the law-abiding citizen far back into the times of early history; the tendency to vagrancy, the dislike to settled habits, the hatred of control being so ingrained in a certain proportion of the human race, that the genus tramp—with all its dirt and tendency to spread disease—has always been able to hold its own against the laws, often harsh and cruel, which have for ages been leveled against it; and we certainly must not allow any hope or expectation of an advancing civilization leading to the extinction of the race to stand in the way of such measures as may be found necessary to prevent the evils arising from its nomadic habits.

"Dr Ring pointed out how frequently epidemic diseases were carried into new districts by tramps, and how common lodging houses and casual wards became dispersion points for infection. Dr. Armstrong* also has shown the immense importance of vagrancy in the dissemination of small-pox: seventy-three per cent. of the urban districts in which small-pox had occurred, and from which he got returns, having sooner or later been infected by vagrants, many of them having had it introduced in the same way over and over again. The case, in fact, in regard to small-pox is so strong that perhaps the discussion drifted unduly in the direction of compulsory revaccination as a way out of the difficulty, for the probability is that a mode of dissemination proved in one disease operates in others, and that many a strange and unaccountable outbreak of diphtheria or scarlet fever dates back to the cup of water given by a villager to some passing tramp.

"Unfortunately, the remedies proposed all touch freely on that thorny question—the liberty of the subject. Compulsory detention, revaccination, and disinfection, with compulsory reporting of their movements, and even, as recommended by Dr. Ring, the registration of their comings-in and goings-out on a card carried for the purpose, form the staple of the suggestions which were made; but when one realizes that we have to deal with people who dislike jail chiefly because it brings them under the ken of the authorities, and to whom the 'ticket,' with its suspicious resemblance to a ticket of leave, would send a greater punishment than the penalty for not using it, we begin to see some of the difficulties with which the question is hedged around. Nor are these lessened by the fact that, although tramps form a class apart, separate, and distinct from the rest of the community, they are intimately mixed up in their haunts and their movements with the unemployed poor. However much it may be insisted on that the tramp requires severe measures, the only places where he can be caught to be dealt with at all are the casual wards and the common lodging houses, in both of which he is mixed up with a crowd of unfortunates, out-of-workers, and ne'er-do-wells, who by no means deserve the same severity; and although it may be true that an experienced officer can pick out the tramp at a glance—nay even, as was suggested, at a sniff—that is hardly the sort of evidence on which it would be right to condemn any one to exceptional treatment.

"We, like the Hindus, have our fairs and great gatherings, although with less religious aims, and ours, like theirs, doubtless act as disseminators of disease. Hop picking, harvesting, and strikes, all set up large movements of the poorest of our population, who become intermingled in our casual wards and lodging houses with detachments of that great army of sixty thousand vagrants which is said constantly to perambulate our country, and, efficacious as it might be from a sanitary point of view to treat all these people like ticket-of-leave men, we hardly think it probable that Parliament would be induced to take that view.

"In the mean time our authorities might certainly apply with greater vigor the powers which they have. Little control as we have over the tramp himself, we do already possess considerable authority over the keeper of the common lodging house. If the description of doss houses lately given in the *St. James's Gazette* are to be trusted, these dwellings are far indeed from the perfection which could be enforced by the law even as it now stands, and if it be objected that to make

* *Public Health*, July, 1893.

them clean and decent would render them too expensive for the tramp, we would answer—so much the better. The sooner the tramp can be driven to a reformed casual ward, where at least he can be washed and his rags be disinfected, the better for the country. It would probably well pay the nation to give him both bed and breakfast in return for being allowed to scrub him."

The Pan-American Medical Congress.—The following is published for the information of those of our readers who are delegates to and intend visiting Washington during the sessions of the congress: The Pennsylvania Railroad Company has fixed the rate at one fare and a third for the round trip on all of its lines. Purchasers of tickets at one full fare (\$6.50 from New York) will receive from the ticket agent a certificate which, when countersigned by the chairman of the Transportation Committee, will entitle them to a return ticket at one third fare. Trains leave the Pennsylvania Railroad depot in Jersey City, with ferryboat connections from the foot of Cortlandt and Desbrosses Streets, New York, and with annex boats (thirty minutes earlier) from Brooklyn, and from the Sound line of steamboats, on their arrival, as follows:

Leave New York	8.00 A. M.,	arrive in Washington	1.42 P. M.
" " "	8.30 A. M.,	" " "	3.10 P. M.
" " "	10.00 A. M.,	" " "	3.45 P. M.
" " "	11.00 A. M.,	" " "	4.30 P. M.
" " "	2.10 P. M.,	" " "	8.15 P. M.
" " "	3.20 P. M.,	" " "	8.25 P. M.
" " "	4.30 P. M.,	" " "	10.25 P. M.
" " "	5.00 P. M.,	" " "	10.55 P. M.
" " "	9.00 P. M.,	" " "	4.10 A. M.
" " "	12.15 A. M.,	" " "	7.40 A. M.

The 10.00 A. M. and the 3.20 P. M. trains are composed entirely of Pullman cars, which are attached to all trains, on which the fare is \$1.25 additional.

The Colorado Medical Library Association has issued the following circular:

"Certain members of the medical profession in Denver, realizing that the existence of a medical reference library for Colorado has become a necessity to the enlightened study and practice of medicine, have united and become incorporated under the title of the Colorado Medical Library Association.

"The annual subscription for membership has been placed at \$5.00, and the subscriptions so received will be expended in the purchase of medical literature of a character determined by the nominations of the individual subscribers. The works thus obtained will be placed on the shelves of the Denver Public Library, on the condition that the library will spend on medical literature at least as much money as is subscribed by the association. The power and usefulness of books are increased when they are brought together. To the choice collection of medical works already in possession of the public library, several hundred valuable volumes have recently been added, either as bequests, gifts, or to be held in trust for their present owners. The funds in the treasury of the Medico-legal Society have been devoted to the purchase of appropriate literature to be added to the library.

"The medical department of the library now contains over 800 bound volumes; fifty-five journals are regularly received through subscription, while some seventy-five additional journals are present in incomplete sets. At the present rate Colorado will shortly be in possession of a medical library which will compare favorably with the collections of the East. The present executive committee is as follows: Dr. J. T. Eskridge, president; Dr. Henry Sewall, secretary and treasurer, No. 23 Eighteenth Avenue; Dr. J. C. Dana, librarian.

The Naval Post-graduate School at Brooklyn.—The following-named officers have been appointed to have charge of the new school of instruction for surgeons at the Naval Laboratory at Brooklyn: Medical Director J. H. Clark, president; Medical Inspector C. H. White and Surgeons J. L. Neilson and M. F. Gates. The latter will serve as recorder. The school opened about August 1st, beginning with a class of two scholars, who had recently entered the naval service. The course of instruction will continue three months or longer. The following will be among the subjects of study: Chemistry, hygiene, micro-

copy, bacteriology, ventilation, life-saving, anthropology, and bedside work. The students will have opportunities to visit different naval hospitals and view practically the medical conditions of naval life, hospital establishments on shore and on shipboard, and the causes of diseases among sailors.

Change of Address.—Dr. Ward A. Holden, to No. 37 West Thirtieth Street.

The Death of Dr. George Henry, of Livingstonia, Africa, on July 5th, removed a valuable member of the Scottish pioneer band of missionaries belonging to the Free Kirk. He had a double qualification in medicine from the University of Aberdeen, but he was best known for his marvelous faculty in linguistics. He had command of Hebrew and Arabic quite early, and afterward acquired a good knowledge of Persian, Hindustani, Chinese, and other Oriental tongues. He wrote a grammar of Chinyanja, the dialect of the African tribe with which he passed his later years; he also translated *Pilgrim's Progress* and a hymn-book. He died of African fever.

The Death of Dr. Oliver H. Bartine, of Princeton, New Jersey, occurred on August 24th. He was seventy-eight years old. He was graduated in 1859 from the Philadelphia Medical College. He was mayor of Princeton at one time, and always prominent in public improvements. He died, after a short illness, of paralysis.

Army Intelligence.—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from August 20 to August 26, 1893:*

By direction of the Secretary of War, a board of medical officers—to consist of ALDEN, CHARLES H., Colonel and Assistant Surgeon General; FORWOOD, WILLIAM H., Lieutenant Colonel and Deputy Surgeon General; SMART, CHARLES, Major and Surgeon; REED, WALTER, Captain and Assistant Surgeon; and MERRILL, JAMES C., Captain and Assistant Surgeon—is constituted to meet at the Army Medical Museum Building, in this city, on the 11th day of September, 1893, for the examination of candidates for admission to the medical corps of the army. Par. 1, S. O. 193, Headquarters of the Army, A. G. O., Washington, August 23, 1893.

A board of officers—to consist of ALDEN, CHARLES H., Colonel and Assistant Surgeon General; FORWOOD, WILLIAM H., Lieutenant Colonel and Deputy Surgeon General; and CORSON, JOSEPH K., Major and Surgeon—is, by direction of the Secretary of War, appointed to meet at the Army Medical Museum Building, Washington, on Monday, September 4, 1893, for the examination of such officers as may be ordered before it to determine their fitness for promotion.

By direction of the Secretary of War, the following-named medical officers are detailed to represent the Medical Department of the Army at the Pan-American Medical Congress to be held in Washington, D. C., September 5 to 8, 1893: IRWIN, B. J. D., Colonel and Assistant Surgeon General; BACHE, DALLAS, Lieutenant Colonel and Deputy Surgeon General; HUNTINGTON, DAVID L., Major and Surgeon; and SMART, CHARLES, Major and Surgeon.

ALDEN, CHARLES H., Colonel and Assistant Surgeon General, on being relieved from duty as medical director, Department of Dakota, will proceed to this city and report to the Surgeon General, U. S. Army, for duty in his office, and as president of the Army Medical School, Washington, D. C.

POWELL, J. L., Captain and Assistant Surgeon, is hereby granted leave of absence for one month, with permission to apply for an extension of ten days.

WOLVERTON, WILLIAM D., Lieutenant Colonel and Deputy Surgeon General, is relieved from duty at Watervliet Arsenal, New York, and assigned to duty as medical director, Department of the Columbia, to relieve BYRNE, C. C., Lieutenant Colonel and Deputy Surgeon General.

BYRNE, C. C., Lieutenant Colonel and Deputy Surgeon General, on being relieved from duty as medical director, Department of the Columbia, will report for duty as medical director, Department of Dakota, to relieve ALDEN, CHARLES H., Colonel and Assistant Surgeon General. SHILLOCK, PAUL, Captain and Assistant Surgeon (in the field), is granted leave of absence for one month, to take effect about September 1,

1893, with permission to apply for an extension of fifteen days. The commanding officer, U. S. troops in the field near Fruitland, New Mexico, is authorized to employ a citizen physician in cases of necessity during the absence of Captain Paul Shillock, Assistant Surgeon.

By direction of the Secretary of War, the following-named officers will report in person to Colonel C. H. Alden, Assistant Surgeon General, president of the examining board appointed to meet at the Army Medical Museum Building, September 4, 1893, for examination for promotion: PRICE, CURTIS E., Captain and Assistant Surgeon; COMEGYS, E. T., Captain and Assistant Surgeon; REED, WALTER, Captain and Assistant Surgeon; and MERRILL, JAMES C., Captain and Assistant Surgeon.

CARTER, WILLIAM F., Captain and Assistant Surgeon, is granted leave of absence for one month, to take effect upon the return of Assistant Surgeon Glennan from leave.

BROWN, JUSTUS M., Major and Surgeon, is relieved from duty at Fort Meade, South Dakota, and assigned to duty at Fort Wayne, Michigan.

GIBSON, R. J., Captain and Assistant Surgeon, is granted leave of absence for one month.

Naval Intelligence.—*Official List of Changes in the Medical Corps of the United States Navy for the week ending August 26, 1893:*

BLOODGOOD, D., Medical Director. Placed on retired list, August 20, 1893.

WINSLOW, GEORGE F., Surgeon. Detached from the Monterey and ordered to the Philadelphia.

HOEHLING, A. A., Medical Director. Appointed president of the board to examine applicants for admission to the Naval Academy.

SMITH, G. T., Passed Assistant Surgeon. Detached from the Baltimore and ordered to the Wabash.

KENNEDY, R. M., Passed Assistant Surgeon. Detached from the Wabash and ordered to the Baltimore.

STONE, L. H., Assistant Surgeon. Detached from the Naval Hospital, New York, and ordered to the Minnesota.

PAGE, J. E., Assistant Surgeon. Detached from the Minnesota and granted sick leave for three months.

Marine-Hospital Service.—*Official List of the Changes of Stations and Duties of Medical Officers of the United States Marine-Hospital Service for the eight weeks ending August 5, 1893:*

FESSENDEN, C. S. D., Surgeon. To proceed to Mobile, Ala., for duty. June 16, 1893. To proceed to New Orleans, La., as Inspector. August 1, 1893.

MURRAY, R. D., Surgeon. Granted leave of absence for seven days. June 21, 1893.

VANSANT, JOHN, Surgeon. To proceed to Wilmington, N. C., for duty. June 16, 1893.

AUSTIN, H. W., Surgeon. To inspect Delaware Breakwater Quarantine Station. July 22, 1893.

GASSAWAY, J. M., Surgeon. To proceed to Detroit, Mich., and Chicago, Ill., as Inspector. July 12, 1893.

IRWIN, FAIRFAX, Surgeon. Detailed for duty in office of the United States Consul, London, England. July 2, 1893.

CARTER, H. R., Surgeon. To proceed to Brunswick, Ga., for temporary duty. June 28, 1893.

PECKHAM, C. T., Passed Assistant Surgeon. Granted leave of absence for six days. June 22, 1893.

BROOKS, S. D., Passed Assistant Surgeon. Granted leave of absence for three days. June 22, 1893.

CARRINGTON, P. M., Passed Assistant Surgeon. Detailed for duty in office of the United States Consul, Bremen, Germany. June 15, 1893.

KINTOUN, J. J., Passed Assistant Surgeon. To rejoin station, Washington, D. C. July 10, 1893. To inspect Camp Low, New Jersey. July 29, 1893.

GOODWIN, H. T., Passed Assistant Surgeon. Granted leave of absence for three days. June 12, 1893. To proceed to Louisville, Ky., for duty. July 12, 1893.

VAUGHAN, G. T., Passed Assistant Surgeon. To proceed to Chicago, Ill., for temporary duty. July 10, 1893.

GEDDINGS, H. D., Passed Assistant Surgeon. To proceed to Delaware Breakwater Quarantine for duty. June 30, 1893.

PERRY, J. C., Passed Assistant Surgeon. To proceed to Portland, Me., for temporary duty. July 8, 1893.

SIMPSON, W. G., Assistant Surgeon. Detailed for duty in office of the United States Consul, Glasgow, Scotland. July 7, 1893.

GARDNER, C. H., Assistant Surgeon. Granted leave of absence for fourteen days. July 19, 1893.

STRAYER, EDGAR, Assistant Surgeon. To proceed to Vineyard Haven, Mass., for temporary duty. July 8, 1893.

OAKLEY, J. H., Assistant Surgeon. To proceed to Wilmington, N. C., for temporary duty. July 24, 1893.

NORMAN, SEATON, Assistant Surgeon. Granted leave of absence for three days. July 24, 1893.

BRANHAM, J. W., Assistant Surgeon. To proceed to Brunswick, Ga., for temporary duty. July 25, 1893.

SPRAGUE, E. K., Assistant Surgeon. Granted leave of absence for fifteen days. July 22, 1893.

PROCHAZKA, EMIL, Assistant Surgeon. Relieved from duty at Ellis Island, N. Y., and ordered to report to medical officer in command, New York. July 29, 1893.

Letters to the Editor.

HAHNEMANN'S "HYDROPHOBIN."

LINCOLN, NEB., August 22, 1893.

To the Editor of the New York Medical Journal:

SIR: In the August 12th issue Dr. George F. Laidlaw requests my authority for the following statement, which occurs in an article of mine under the title *Organic Juices in Therapeutics*, published in the *Journal* of June 10, 1893:

"Hahnemann, in the early part of the present century, experimenting along the same isopathic curve, refined the crude therapeutics of the Greek and used 'hydrophobin' in the treatment of rabies."

Dr. Constantine Hering and Dr. G. H. G. Jahr both studied medicine under Hahnemann himself. Dr. Jahr wrote a work on homeopathic medicine known as *Jahr's Clinical Guide*. It was translated into English by Charles J. Hempel, M. D., who also had read medicine under Hahnemann. On page 274 of this work "hydrophobin" is recommended in the treatment of hydrophobia. On account of the intimate relations that must necessarily have existed between the famous protégé of the Grand Duke of Anhalt-Köthen and his now scarcely less famous pupils, it is but fair to assume that they faithfully reflected both his doctrine of "similars" and "infinitesimals." The statement in question is further justified by a reading of the preface to the *Clinical Guide*, in which Dr. Lilienthal, the editor, says that Dr. Jahr's work "is too valuable a work not to be clothed in the English language, in order to assist the many students who have embraced with heart and soul the glorious doctrines of Hahnemann." J. S. LEONHARDT, M. D.

CASTOR OIL AS A LUBRICANT.

INDIANAPOLIS, August 28, 1893.

To the Editor of the New York Medical Journal:

SIR: In confirmation of the views expressed by Dr. A. T. Cabot, in your issue of August 26, 1893, permit me to say that I have used castor oil as a lubricant for all kinds of catheters for over seven years, and prefer it to all others. It is non-

irritating and possesses the quality of tenacity beyond all other lubricants. If refined oil is selected and proper care used an antiseptic is an unnecessary addition, as I know one gentleman who has used the oil for the purpose stated above over five thousand times, with only good results. Always warm the oil before using and see that the phial containing it is frequently well washed with alcohol.

The external surface of the soft-rubber catheter is easily cleaned by drawing the instrument rapidly between the fingers, a bit of absorbent cotton saturated with alcohol being interposed, and this should be followed by the free use of warm carbolyzed water. Silk catheters may be washed in the same way, but *without* the alcohol; indeed, castor oil seems to benefit rather than injure these catheters. The gentleman heretofore alluded to used one twice daily for a period of eight months, and it was then nearly as smooth and quite as flexible as when new.

JOHN M. KITCHEN, M. D.

THE RECRUDESCENCE OF LEPROSY AND ITS CAUSATION.

LONDON, July 29, 1893.

To the Editor of the *New York Medical Journal*:

SIR: My attention has been called to the notice of my recent volume, *The Recrudescence of Leprosy and its Causation*, in the *New York Medical Journal*. Your critic says: "The author has assumed that leprosy has greatly increased during the last half century—an assumption that is without warrant, absolutely disregarding as it does that the *onus probandi* rests upon the assertor." Allow me to say in explanation that I recognize the responsibility of proving every one of the leading points of my contention, and if your reviewer had done me the honor of reading the first chapter of my volume he would have found not only reports of my own experience gathered from all quarters of the globe showing that leprosy has seriously increased during the past thirty years, but he would have discovered proofs to this effect from the highest medical authorities, including lepra specialists, superintendents of leper asylums, hospital physicians, and in Government reports. This chapter contains about sixty pages of closely packed testimonies and has evidently escaped the attention of your reviewer. One of the most distinguished members of the National Leprosy Fund, Sir Andrew Clark, declared, at a meeting over which the Prince of Wales presided, that the evidence was conclusive and overwhelming "that leprosy did exist in larger measure in recent years and that new germ centers were springing up in various quarters of the globe and old centers were widening. Before England and the civilized world there was looming a condition of affairs which might by growth threaten civilization." It is therefore useless to deny or attempt to minimize facts which are proved by an accumulation of testimony of the highest credit and authority.

Coming to the question of causation, to which I have devoted much attention, having examined into the evidence for all the various alleged factors, such as heredity, contagion, insolation, syphilitic cachexia, a fish diet, malaria, etc., and have quoted what the most eminent authorities have to say thereupon. All these factors, allow me to observe, have been in existence for centuries, and do not account for the recent alarming recrudescence of the disease. Upon each of them there is considerable divergence of medical opinion, as I have shown. What one authority affirms another denies, and the investigator, however patient he may be, is left in a state of hopeless bewilderment. There is, however, one cause upon which, in all the countries I have visited, there is no such confusion, but a nearly unanimous consensus of intelligent opinion—I mean inoculation. About forty pages of testimonies and

experiences are given under this head, which include those of the leading medical journals and some of the most eminent pathologists, lepra specialists, and hospital physicians in all countries. As accidental inoculation is not of sufficient frequency to account for so large a development of the disease, it follows that there must be some other cause, and that of an innovating character, or a comparatively new departure. This cause, I maintain, is vaccination, which is the only form of inoculation generally practiced, and meets the case at all points. Vaccination is admitted, though with reluctance, and sometimes with apology, by the highest authorities to be capable of transmitting and aiding the ravages of this much-dreaded disease. The authorities on this part of my case include Sir Erasmus Wilson, the father of dermatologists; Dr. John D. Hillis, formerly superintendent of the Leper Asylum, British Guiana; Dr. Liveing, Sir Ranald Martin, Professor W. T. Gairdner, of Glasgow; Dr. Tilbury Fox, Sir Gavin Milroy, Dr. R. H. Bakewell, formerly vaccinator-general, Trinidad; Dr. A. S. Black, Trinidad; the eminent bacteriologist, Dr. Edward Arning, Hamburg; Professor H. G. Piffard, New York; Dr. Walter Gibson, late president of the board of health, Hawaii; Dr. Blanc, professor of dermatology, New Orleans; Dr. Sidney Bourne Swift, late medical director of the leper settlement, Molokai, Hawaii; Dr. P. Hellat, St. Petersburg; Professor Henri Leloir, Lille; Surgeon Brunt, Dr. John Freeland, government medical officer, Antigua; Dr. S. P. Impey, superintendent of the leper settlement, Robben Island, Cape Colony; Dr. H. S. Orme, president of the State board of health, California; and many others.

For the first time there have been brought together some of the incriminating facts, comprising nearly one hundred pages of closely packed testimonies—nearly all medical—as to communication of leprosy by means of vaccination, and in addition I have given particulars of numerous cases of such communication with chapter and verse by the recording physician.

WILLIAM TEBB.

Book Notices.

Diseases of the Rectum and Anus, their Pathology, Diagnosis, and Treatment. By CHARLES B. KELSEY, A. M., M. D. Professor of Diseases of the Rectum at the New York Post-graduate Medical School and Hospital, etc. Fourth Edition, revised and enlarged. With Two Chromo-lithographs and One Hundred and Sixty-two Illustrations. New York: William Wood & Company, 1893. Pp. x-490. [Price, \$4.]

PRECEDING editions of this valuable work have been reviewed in the *Journal*, and, as its general plan and subject matter are practically unchanged, we can but reiterate the high opinion of it which we have heretofore expressed. The new material in the present edition is largely confined to the chapters upon ulceration and malignant disease of the rectum. The author's enlarged experiences with these diseases has not given him the enthusiasm of some other surgeons in regard to extirpation and resection of the rectum. While he has thoroughly mastered and ably described the various methods, including the many modifications of Kraskie's operation, he still believes that, in the state in which most cases of malignant disease are seen by the specialist, as much can be done for them by inguinal colotomy as by the more radical procedures. He says: "While it has been abundantly demonstrated that very extensive disease may be removed, and the technique of the operation has been so greatly improved that nearly any part of the rectum may be reached and extirpated rapidly and with comparative safety as to the

immediate results, the advisability of such treatment has not as yet been established. The operations are done because they are manually possible and surgically justifiable."

To those who have followed the clinics in New York for the past five years the statement that the operation can be done rapidly will appear somewhat surprising. The majority of these operations consume from an hour to three hours, and this fact has caused many to doubt that the procedures were justifiable in the cases of patients already depleted by disease. The technique may be complete, but the manual dexterity requisite to perform the operation in from fifteen to twenty minutes, as Bardenheuer professes to do, has not been developed in our clinics. When it has, as the writer believes it will be, the operation will become more popular. The author's opinion, in the present state of our knowledge and experience, is undoubtedly conservative and just.

As regards the treatment of hemorrhoids, Dr. Kelsey may be said to have "swung around the circle," having in turn indorsed and condemned almost all the leading operations. He has in the present edition about settled upon the use of the clamp and cautery as the method *par excellence*, but leaves a limited field to crushing, the ligature, Whitehead's operation, and injection. Few who depend upon this work for advice would dare to use the last, however, when they are told that it is attended with dangers of "pain, ulceration, marginal abscess, fistula, and vesical irritation," and that it does not cure.

These complications, while possible, we dare say are not so frequent as the author would seem to imply, where the operation has been properly done in well-selected cases. Moreover, there is not one of these complications that may not result from either of the other operations. We heartily agree with Dr. Kelsey in his high estimation of the clamp and cautery, but we do not believe their use possesses all the advantages or the injection method all the disadvantages in the treatment of hemorrhoids.

The work as a whole is an admirable *résumé* of the subject up to date, and we are glad to see the author reaping the reward of his labors in its frequent editions.

BOOKS, ETC., RECEIVED.

The Pharmacopoeia of the United States of America. Seventh Decennial Revision (1890). By Authority of the National Convention for revising the Pharmacopoeia. Held at Washington, A. D. 1890. PUBLIC HEALTH, HYGIENE, LEGAL MEDICINE, AND MEDICAL AND VITAL STATISTICS.

By S. T. ARMSTRONG, M. D., Ph. D.

A Russian Appeal for the Sanitation of India.—The *British Medical Journal* for March 25th states that Dr. Tafeluss, of Tiflis, who has held for many years the appointment of quarantine officer on the Russo-Persian frontier, makes an appeal for the sanitation of India. He refers to the fact that the home of cholera is in the delta of the rivers Ganges and Brahmapootra, an area of 7,500 square miles, that is crossed by many tributaries of these rivers. Cholera has there had the character of an endemic plague from time immemorial, and, after heavy rains and by reason of some other unknown causes, spreads over the neighboring parts of India, sometimes traveling as a pandemic over the world. Dr. Tafeluss proposes that all our energy should be directed to that country, and, first of all, the contamination of the rivers by dead bodies thrown into them by the natives should be stopped; he reminds us that in Egypt, in the delta of the Nile, the plague has been rooted out since an ordinance was passed forbidding the burial of dead bodies close to the shore. Before that time, every year the bodies were washed out by the tide and carried to the river's mouth, where they lay about *en masse*.

Although it would be very difficult to forbid altogether the throwing of bodies into the sacred Ganges, Dr. Tafeluss thought it would be quite possible to compel the natives to cremate thoroughly, and not merely roast the bodies of their dead. The pure ashes would not do much harm. Secondly, he recommends the planting of eucalyptus trees throughout India; these would absorb the moisture of the soil and exterminate all miasmatic material, as has been shown in Algiers, where large areas of unwholesome land have been in a short time transformed into healthy and inhabitable places.

Thirdly and chiefly, Dr. Tafeluss proposes an entire canalization and drainage of the delta that would undoubtedly conduce to the sanitation of the country. As to the expense necessary for so great an enterprise, he presumes that it could hardly exceed the amount of money that is now lost at every epidemic by the populations of the various countries affected, to say nothing of the loss of millions of lives. Great Britain, instead of being damaged in her trade as she is by every pandemic, would be enriched by the addition of fertile and wholesome provinces. He does not want England alone to bear the whole burden of the sanitation of India. It is just that the governments of all the countries interested should join her in the great work of a radical stamping out of the cholera, because all of them would share in the benefits of such a work. The money might be raised by a loan guaranteed by the several governments, that might be, if necessary, supplemented by a lottery.

Cholera and Indian Water Supplies.—The *British Medical Journal* for June 3d states that the recently published report of the Sanitary Commissioner for Bengal for 1891 shows that in that year the cholera mortality amounted to 229,575, or 3.26 in

1,000 of population. The facts detailed in this report leave very little doubt that the festival of the *Aradhodayajog*, that attracted "swarms" of pilgrims from all parts of Bengal to the Ganges and its branches, contributed materially to this result. The influence of pilgrims and pilgrimages in breeding and spreading cholera has been questioned by sanitary agnostics, and Dr. Simpson's demonstration of the manner in which this very festival caused a severe outbreak of cholera in and around Calcutta, and an extensive dissemination of the disease in the surrounding districts, was disparaged not long ago by the Army Sanitary Commission. Great weight is placed on the intimate relations that exist between the prevalence of cholera and the impurity of water.

A Bacteriological Study of Cholera as observed in 1892 at the Saint-Antoine Hospital.—Dr. Lesage and Dr. Macaigae publish in the *Annales de l'Institut Pasteur* for January 25th a bacteriological study of 201 cases of cholera treated in the service of Dr. Hayem during the last epidemic of cholera in Paris and its environs. The fecal discharges were as follows: In 52 cases there were rice-water stools, sometimes very watery, containing gray flakes in suspension, sometimes a gray mush, of which epithelial elements were the base. In 56 cases there were green biliary stools with chemical reactions, showing that the color was due to biliverdin. In 83 cases the stools presented no special characteristic, being yellow and frequently glairy. In 10 cases the stools presented a red, dysenteric tint, due to the presence of blood. In 106 patients that recovered a bacteriological examination of their stools showed the cholera vibrio and the *Bacterium coli commune* in 29 cases; the cholera vibrio, the *Bacterium coli commune*, and other bacilli in 62 cases; the *Bacterium coli commune* only in 3 cases, and the *Bacterium coli commune* and other bacilli without the cholera vibrio in 12 cases. In none of the fatal cases (95) was the cholera vibrio alone found in the fæces. The authors conclude that in the epidemic of cholera, as observed at the Saint Antoine Hospital, there were several microbic varieties of cholera that were clinically indistinguishable. In those cholera cases in which the cholera vibrio was found it was always associated with the *Bacterium coli commune* or some other varieties of micro-organisms. A certain number of cases may be described as cholera due to the *Bacterium coli commune*. There is no relation between the number of cholera vibrios in the stools and the severity of the disease, for simple diarrhoeal stools sometimes contain an abundant culture of vibrios. The gravity and the mildness of the disease are alike observed in the various bacteriological varieties of cholera, the presence of the vibrio being an unnecessary factor. The reaction (systemic) caused by cholera seems to be due to a secondary infection by the *Bacterium coli commune*, the presence of which was demonstrated in various organs immediately after death.

The Dissemination of Cholera Bacilli by Dust.—Dr. Uffelmann publishes a paper in the *Berliner klinische Wochenschrift* for June 26th in which he refers to the prevalent idea that the death of the cholera spirillum in consequence of desiccation prevents its transmission through the air. He has made some experiments to determine whether cholera spirilla can remain alive in dust, and whether they can be disseminated with dust by the air. Sterilized garden earth was rubbed up in porcelain dishes with water containing the spirilla, and then exposed to a temperature of 15° to 17° R.; it dried in some sixteen hours, and was powdered and added to nutrient gelatin at varying intervals of time after the desiccation. In a specimen taken after sixteen hours thirty to forty colonies were found, while only one colony was found in a specimen taken after forty-eight hours, and none were found after the latter period.

In another series of experiments the inoculated earth was

allowed to remain untouched for eight hours after the pulverization; some of it was then blown against a gelatin plate in an isolated chamber, and six colonies of cholera spirilla were obtained. When the interval was forty-eight hours after infection no colonies were seen. Similar results were obtained with fine white sand, with street dust, and with chamber dust, though the spirilla seemed to perish earlier. Experiments were made with cholera spirilla added to diarrhoeal stools after the latter had been sterilized, with similar results, though the spirilla seemed to live a little longer. It would therefore seem that living cholera spirilla may be disseminated with dust and thus gain entrance into the mouth, the food, or water. Dr. Uffelmann, however, calls attention to the fact that this method of dissemination can not be very frequent, because the number of spirilla is rapidly diminished by drying, because material contaminated by fæces does not give rise to dust, and because, as Sternberg's elaborate experiments have shown, the spirilla soon perish when exposed to sunshine.

Flies as Propagators of Cholera.—Dr. J. G. Sawtschenko publishes in *Vratch*, vol. xiii, 1892 (*Annales de l'Institut Pasteur*, February 25, 1893), a valuable paper on the rôle played by the ordinary house fly in the propagation of cholera. The author has nurtured flies with bouillon containing a culture of the cholera vibrio, and then has subsequently searched for the micro-organism in the excrement of these insects. Two hours after feeding the flies with this bouillon the author obtained, besides a large number of colonies of different bacteria, a few colonies of the cholera vibrio. Twenty-four hours after feeding, the number of colonies of the cholera vibrio had materially increased.

In order to be certain that these microbes did not adhere to the exterior of the fly, Dr. Sawtschenko made another series of experiments in which he plunged the flies first into alcohol and then into a five-per-cent. solution of carbolic acid, so as to destroy any micro-organisms on the insect's body; the latter was rapidly dried, the body was opened, and its contents were introduced into a bouillon culture fluid. In every instance the number of cholera vibrios was considerable, and the number was always greater when the flies were allowed to live for some time after feeding on the bouillon cultures containing the vibrio. In flies that had lived forty-eight hours, the second or third culture made from the culture containing the body contents resembled pure cultures of cholera vibrios.

The author, apparently correctly, infers that his observations show that the rôle of the fly is not limited to diffusing the microbes that may be swallowed, but that the cholera micro-organisms may easily propagate in the intestinal canal of the insect. Other microbes, especially the vibrio described by Metschnikoff, preserve their virulence while passing through the fly's body.

Rags and Cholera.—The *Boston Medical and Surgical Journal* for June 8th publishes an excellent editorial on rags and cholera, in which attention is called to the fact that, while commercial interests and the protection of public health occasionally clash, still the restrictions that are devised for securing safety to the people should be neither oppressive nor unreasonable. Particular reference is made to some recent foreign correspondence of the *New York Times*, the tenor of which was calculated to make the reader believe that large quantities of rags from cholera-infected districts, and therefore cholera-infected rags, were being imported into the United States. The editorial very pertinently calls attention to the fact that, though rags are dirty, and are occasionally the medium of transmission of the infection of small-pox, yet during the sixty years in which this merchandise has been imported into the United States, during which period several cholera epidemics have oc-

curred, not a single case of cholera has ever been traced to their importation. Furthermore, no well-authenticated case of cholera has ever been reported as due to such traffic in any other country. The editorial calls attention to the facts, that have been urged in the columns of this *Journal*, that the permanence or vitality of the cholera germ differs very greatly from that of the germ of small-pox or of some of the other contagious diseases, and that writers upon this subject usually make no distinction between clothing and rags, as was shown in the sensational address of a Dr. Ruysch at the International Congress of Hygiene in 1884.

Reference is made to the experience of Holyoke, where, in 1849, several thousand laborers were engaged in building a dam and laying the foundations of the city. Cholera broke out among these laborers and caused the death of almost a hundred; yet in the following year paper mills were built and their number was increased until Holyoke became the largest paper-making and rag-using city in this country, but cholera has never appeared there since, in the epidemics of either 1854, 1866, or 1873. Hearty commendation must be given to the final sentences: "If the alarmists who are periodically clamoring for restriction upon this important industry would turn their attention seriously to the more important measures of municipal sanitation, and especially to the purification of water supplies, wherein the chief danger lies, a great public good would be accomplished, though possibly their personal ends would not be as well subserved. Much would also be gained if newspapers and their correspondents would abstain from sensationalism under existing circumstances."

The Disinfection of Rags by Sulphurous-acid Gas.—Mr. J. C. Kellogg, our consul at Stettin, and Dr. G. Laube, an analytical chemist of that city, publish in the *Abstract of Sanitary Reports* for April 21st the results of a series of qualitative and quantitative analyses of rags disinfected by exposure to sulphurous-acid fumes in tightly closed rooms. The tests with metallic zinc and hydrochloric acid, with nitrate of silver, with sulphureted-hydrogen gas, with chloride of gold, and with mercuric nitrate, all gave the reaction of sulphurous acid with the disinfected rags. Quantitatively, rags from the exterior of the piles contained more sulphurous-acid gas than those from the interior of the piles. Mr. Kellogg correctly suggests that the disinfection would be more efficacious if the rags were first baled and then subjected to the action of the gas *in vacuo*. There has never been any question regarding the access of the gas to the rags, but it is yet to be determined whether the gas is present in sufficient quantity, and whether the exposure is sufficiently long to destroy both germs and spores.

Leprosy in India.—The *British Medical Journal* for April 29th publishes an abstract of the report of the English Leprosy Commission that spent five months in examining asylums and lepers in various localities in India. An analysis of 2,313 cases showed that 56.6 per cent. were anæsthetic, 12.2 per cent. tuberculous, and 31 per cent. mixed leprosy; in over 43 per cent. the disease first manifested itself in early adult life; 9.5 per cent. of the persons produced as lepers were not affected with the disease. The Indian census figures prove that, with regard to the geographical distribution of leprosy, all tracts—sea coast, riparian areas, or large valleys—are more or less impartially attacked. No connection can be traced between the geological formation of an area and the density of the leper population. A comparison of the first, second, and third censuses of India shows that the leper population has remained stationary, being approximately 5 to 10,000 of population for each census. There seems to be some connection, accidental or other, between the dampness of climate and the prevalence of leprosy, though no relation between the heat of an area and the distribution of

the disease could be established. No relation between the increase or decrease or the density of the population and the leper ratios could be made out. Areas where cholera is endemic present certain permanent conditions that may lead to a predisposition to leprosy. Poor and insanitary conditions, bad social surroundings, and so forth, seem to be factors of importance in the ætiology of the disease.

The commission assumes the virus to be too widely spread to be battled against, just as it would be hopeless to attack the tubercle bacillus. They point out that contagion is an extremely relative term, and that the most general causes may convert a non-contagious infective disease into an easily contagious one. The commission advises that the social or hygienic conditions responsible for the development of the special predisposition should be removed or improved.

The important conclusion is formulated that leprosy in India can not be considered an hereditary disease, and the statement is ventured that the evidence that exists is hardly sufficient to establish an inherited specific predisposition, to any appreciable extent, to the disease in the offspring of leprosy parents. This conclusion was based upon the facts that a congenital case of leprosy was never met with; that in only 5 to 6 per cent. of the cases examined was there a possible true family taint; that 4 to 5 per cent. of the offspring suffered, although their immediate ancestors were free from leprosy; that only 4 to 7 per cent. of the children born of leprosy father and mother (both affected before marriage) became lepers; that with one exception all the children at the Almora Orphanage, born of leper parents, but separated from them and carefully looked after, remained healthy; that not more than 6 or 8 per cent. of all the children born after the manifestation of the disease in one or other parent became lepers; and that individuals with a true history of heredity were no more predisposed to the disease than those with a false history of heredity (where parents had become lepers some time after the birth of the child).

The commissioner's statistics show that 2,915 individuals have been the issue of 1,564 marriages, the latter representing 1,635 lepers; at the time of the report only 78 of the 2,915 were lepers, and, according to previous statistics, it is improbable that more than 150 will become hereditary lepers. The mortality among leper offspring is comparatively high, and the reproductive power of lepers is greatly diminished on account of the extensive morbid changes in the sexual glands. Of leper couples, 65 per cent. are sterile; where the husband is a leper, 60 per cent. become sterile after the appearance of the disease in him; and where the wife alone is a leper, 70 per cent. are sterile after the manifestation of leprosy in her.

The commission has arrived at the conclusion that, though leprosy must be classed among the contagious diseases, yet the risk of contagion is so small that it may be practically disregarded. It is far from being an "imperial danger." In the great majority of cases it originates *de novo*—that is, from a sequence or concurrence of causes and conditions, dealt with in the report, that are related to each other in ways at present imperfectly known. In other words, the microbe may reach the body and set up the disease quite apart from contagion, if only the required disposition exists.

The Effectual Filtration of River Water.—The *British Medical Journal* for June 24th states that at a recent meeting of the Royal Commission on the Metropolitan Water Supply, Dr. Sims Woodhead called attention to the fact that only two diseases—typhoid fever and cholera—need be taken into account in connection with the water supply. It had not been proved that the flow of rivers led to the destruction of the typhoid bacillus, but as a matter of fact that organism had never yet been found in rapidly flowing water, but in sluggish water, ponds,

wells, and stagnant pools. Dr. Woodhead thought that if everything was done that could be done to prevent river pollution, the danger of disease arising from taking drinking water from the Thames would be extremely small, provided the water was properly filtered. Efficient filtration removed dangerous organisms to, at any rate, a very large extent; still, river water must always be under suspicion. A perfect single filtration might be sufficient, as the thickness of the filter would be of far greater value in a single filter than the same thickness divided between two filters; the thickness should never be less than three feet. As the principal layer of the sand kept back a number of organisms that might grow therein, and thus extend downward into the filter bed, the sand layer should be sufficiently thick to keep back the organisms and allow the lower layers of the filter to be some distance from the sand.

Public Water Service in Relation to Typhoid Fever.—

The *Practitioner* for January publishes a résumé of two reports that were recently issued by the Medical Department of the Local Government Board on outbreaks of typhoid fever in different localities that could be traced to infection from a common water supply. The reports seem to show, first, that a definite and serious danger of typhoid fever and of allied diseases, such as cholera, attaches to the use of water derived from lands that are either subject to manuring with human excreta or polluted by means of drainage from dwellings or from streams that are liable to pollution with sewage or human excreta. Second, that there seems to be abundant evidence pointing to the fact that, while water supplies from such sources afford well-recognized means for the maintenance of typhoid fever as a current infectious disease among its consumers, there is further risk of an exceptional prevalence of that disease when the manure used on the ground from which the water is gathered, or when the sewage reaching the stream, comes from dwellings the excreta from which contain the specific contagion of typhoid fever; and this especially when, by reason of exceptional rainfall or otherwise, this contagion is conveyed in bulk into the water drawn into the reservoirs and service pipes from which the inhabitants are supplied. Third, that measures should be adopted to prevent the access of house drainage into the water collected from such gathering grounds and streams, and also to prevent any portion of a gathering ground that serves the purposes of collecting a town water supply from being so used or cultivated as to need manuring in the way described.

The Berlin Sewage Farms and Typhoid Fever.—Professor Virchow, according to the *Medical Week* for February 10th, referred, at a meeting of the Berlin Medical Society, to the occurrence in the summer and fall of 1891 of several cases of typhoid fever among the men employed on the sewage farms in the neighborhood of Berlin. While the affected men had been in the habit of drinking the water from the drains, they also lived in a locality where typhoid fever prevailed. This was the first time that typhoid had been observed in villages near these farms, as they had remained free even when typhoid was epidemic in other localities.

Eight cases were reported in the village where the fever first appeared. The drinking water used by the patients was manifestly impure, but no typhoid bacilli were found in it; since the water supply has been purified no other typhoid cases have occurred.

Although Pasteur stated that sewage farms would assist in the propagation of infectious diseases, especially of anthrax, as the anthrax bacillus was unaffected by water, not a single case of infectious disease has been traced to infection acquired from the sewage farms in Germany. Virchow stated that he insisted on the closest supervision in the management of these farms, each having attached to it a medical man, who was directed to

report every case of disease to the authorities, with all information likely to throw light on the nature and origin of the affection. The bacteriological examination of the effluent water was made by two physicians, and they had never been able to demonstrate the presence of Eberth's bacillus in it.

A slight epidemic of cholera nostras had occurred in one of the villages, affecting the inmates of a prison that were employed on the farms. The disease broke out in one of the sheds in which the prisoners were confined, attacking twenty-one men.

An objection had been made that cattle fed on the crops raised on these farms might become infected because the roots of the grass were in contact with the sewage; but cattle that were fed on nothing but these crops for several months remained in excellent condition.

The Typhoid-fever Epidemic at Ironwood, Michigan.—

The *Journal of the American Medical Association* for July 8th publishes a letter from Dr. Henry B. Baker, the secretary of the Michigan State Board of Health, regarding an epidemic of typhoid fever at Ironwood, a town of about 12,000 inhabitants. The first typhoid-fever cases were reported during the week ending May 20th, when 15 persons had been affected; for the week ending May 27th, 30 new cases; the week ending June 3d, 30 new cases; the week ending June 10th, 125 (estimated) new cases. Up to the latter date only 6 deaths had occurred. The epidemic was ascribed to a number of causes: to the general water supply; to water from wells that had in the past originated autumnal outbreaks of typhoid; to the digging up of filth-saturated soil; to the stirring up and removal during the spring of great quantities of filth that had accumulated during the winter; to a present filthy condition of some gutters and alleys; to atmospheric influences; and to some influence connected with the Ironwood high school. Dr. Baker found no sudden change in any of these conditions that was sufficient to account for the epidemic, except that there had been an unusual overflow in the vicinity of the pumping station for the general water supply. The reservoir had overflowed and probably been contaminated by the excreta of the privy for the engineer's family. [There is no evidence that any member of the family had typhoid fever.] The intake pipe of the pumping station became clogged so as to be useless for several days, and, as it was impossible to filter the water, a break had been made in the reservoir on the downstream side. A sample of the water was examined by Professor Victor Vaughan, who found that it contained pathogenic microorganisms that caused the death of white rats. Dr. Baker advised the boiling of all water for cooking and drinking purposes, that the filter capacity of the works be increased threefold, and that the reservoir for filtered water be cemented inside and outside, so as to be water-tight. The evidence is lacking in this case that the water supply was contaminated by the dejecta of typhoid-fever patients, as occurred in the well-known Plymouth epidemic; and it is possible that other factors caused the epidemic, as no information is given regarding the prevalence of the disease among those using the reservoir and those using well water.

A Method of stating the Degree of Clearness of Sewage and other Contaminated Effluents.—

Dr. A. C. Houston (*Edinb. Med. Journal*, July, 1893) refers to the lack of definiteness in saying that an effluent is more or less turbid. He suggests that on a piece of paper printed with a definite known type—pearl type, for example—a glass beaker or cylinder should be placed. The effluent to be examined is slowly poured into the vessel until the observer, looking down through the fluid, can just read the words through it. The height of the liquid is measured by placing one of the legs of a pair of compasses on the paper and the other on the lower band of the meniscus of

the fluid, the distance between the two points being found by measurement on a scale divided into inches and tenths of an inch. At first sight it would seem better to have a graduated vessel, so as to read off the height of the liquid directly; but if this plan is adopted the difficulty arises that while the focal distance of the eye is constant, the height of the liquid in the cylinder will vary with the quality of the effluent, and in the case of a very turbid fluid it may be a mechanical impossibility to bring the eye within the range of natural vision. For this reason it is necessary to employ beakers or cylinders of varying height and to use the tall or the short vessels according to the quality of the effluent. As a comparative indication of the quality of a particular effluent, the character of which it is necessary to ascertain repeatedly without the aid of chemical analyses, the method is said to be specially valuable.

The Waring Sewerage System.—Some publicity has been given during the past year or so to the statement that the city of Memphis has found the Waring system of sewerage troublesome, that there were obstructions and stoppages in the sewers, and that the city was put to immense cost in removing these obstructions. The president of the Taxing District of Shelby County, as Memphis is legally known, had complained that in the original planning of the sewers no provision was made for manholes, but that the city engineer had projected these manholes and put them in at convenient distances along the mains, thus reducing the removal of obstructions to a minimum. The president has recently published an open letter in which he states that Colonel Waring's original estimates and recommendations provided for manholes for the sewers, but for economy's sake they were not put in at the time the sewers were constructed, in 1880. The wonderful growth of Memphis has greatly taxed the capacity of these sewers, and Colonel Waring has recently inspected the existing situation. He recommends that more efficient flushing should be provided, tanks being constructed that would deliver a hundred and fifty gallons of water in twenty seconds. Such a quantity of water would fill about a hundred and fifteen feet of six-inch sewer pipe and have a scouring effect materially greater than that of the existing flush, and when delivered with rapidity it would—in connection with an occasional ball cleaning—keep the sewers in better condition than could be secured by manual labor. Colonel Waring also recommended that openings should be made in the house connections, near the property line, with suitable movable covers, so as to permit of examination for the purpose of ascertaining whether surface water or underground drainage was flowing into the sewers. Furthermore, as the sewage in time of excessive flow rises in the manholes higher than the sewage stream, and floating filth rises to the surface in the manholes, making a mass of obstructive filth when the flow recedes, the channel through which the sewers pass should be covered with iron plates laid on benches, to keep the solids within the course of the moving current. These plates, if properly supplied with lifting staples, could be conveniently handled.

Bovine Tuberculosis at the Leipsic Abattoirs.—Dr. Rieck (*Vierteljahr. f. gerichtl. Med. u. öffentl. Sanit.*, vol. iv) publishes a paper in which he states that from the opening of the Leipsic abattoirs, in July, 1888, to the end of December, 1891, 67,077 cattle had been killed, and 13,688 of these, or 20.4 per cent., were affected with tuberculosis. Of the cows 26 per cent., of the oxen 19.5 per cent., of the bulls 15.4 per cent., and of the heifers 9.3 per cent., were tuberculous. Annually the percentage of tuberculous cattle had increased, being 14.9 per cent. in 1889 and 26.7 per cent. in 1891. The curve of the percentage of tuberculous cattle pursued a regular course each year, ascending from January to April, and then gradually descending, reaching

the minimum from September to October. Of the 13,688 tuberculous cattle, 11,066 (80.8 per cent.) had the lungs or the bronchial ganglia alone infected. Tuberculosis of the serous membranes was found in 10.8 per cent. of the affected animals, being twice as frequent among the female as among the male animals. It was limited to the pleura in 57.4 per cent. of these animals; it affected the pleura and peritoneum in 36.8 per cent., and it was limited to the peritoneum alone in 5.7 per cent. Rieck invariably found that the neighboring lymphatic ganglia were affected in tuberculosis of the serous membranes. Pleural and peritoneal tuberculosis was more frequent in the female, and pleural tuberculosis in the male animals. There was not sufficient difference in the proportion of peritoneal tuberculosis in the two sexes to support Schneider's idea that the tuberculous infection very frequently had its point of departure in the uterus. Generalized tuberculosis occurred in three per cent. of these animals, most frequently in heifers.

The Inspection of Dairy Herds in Massachusetts.—The Massachusetts Legislature recently enacted a law providing that the officials of each town or city must appoint every year one or more inspectors, whose duty it should be to inspect cattle that were to be slaughtered or from which milk was taken. When an animal having a contagious disease is found, the discovery must be reported to the local board of health and to the secretary of the State Board of Cattle Commissioners. The statute states that tuberculosis, glanders, farcy, Texas fever, rinderpest, rabies, pleuro-pneumonia, and foot-and-mouth disease are the contagious diseases. All herds shall be examined at least once in three months, and a certificate of the health of the animals is to be given to the owner. Diseased animals must be isolated and their milk destroyed. The cattle commissioners may charge to the owner the expense of quarantining and killing diseased animals; their orders shall take precedence over any issued by the local board of health, and violation thereof is punishable by fine.

Typhoid Fever from a Dairy Farm.—The necessity for the sanitary supervision of dairy farms has been recently shown by a local epidemic of typhoid fever at Oakland, Cal. The drainage of the place follows the natural slope from the foothills to the bay. The *San Francisco Examiner* states that within the two weeks ending July 2d more than three hundred cases of typhoid fever had been reported to the local board of health, although until within two months there had not been a case of typhoid fever in the city. At the beginning of the latter time a case of typhoid fever occurred at a dairy farm, and the attending physician states that he exercised every possible sanitary precaution. The patient recovered in some six weeks, and ten days subsequently another case of typhoid occurred at the dairy and simultaneously several cases appeared in Oakland. Within a week after the appearance of the first case in the latter city more than two hundred cases were developed. It does not appear that the attending physician warned the city health authorities or took effective measures to protect those to whom milk from this farm was supplied. The health officer of Oakland reported that more than three fourths of the cases were found in families supplied with milk from this dairy. The dwelling house in which the original cases occurred is situated near a tank or pool, and twenty feet higher than this receptacle; through the grounds of the farm passes a small stream of water, very dirty and greatly defiled with animal excreta and even the rotting remains of dead animals, bones, etc.; the water from this stream runs into the tank, and from this tank was taken the water with which the milk cans were washed.

Alum in Baking Powder.—The *British Medical Journal* for May 5th contains an abstract of an appeal of a grocer con-

victed of selling baking powder containing alum. The public analyst's certificate showed that the powder contained 39 parts of alum, and that official stated that in his opinion the use of alum in bread was prejudicial to health. The correctness of his certificate was not questioned. He stated that by following the instructions on the packet a four-pound loaf of bread would contain three hundred and sixty grains of the powder, and four tenths of that would be alum. The reaction that took place when the powder was used resulted in the formation of aluminium hydrate, sodium sulphate, potassium sulphate, carbonic acid, and water, and the aluminium hydrate formed would average one sixth of the alum. When the bread was eaten the aluminium hydrate was dissolved by the gastric juices and aluminium chloride was formed. To test this latter statement, aluminium hydrate was given with food, the meal was vomited, the vomit was dialyzed through vegetable parchment, and aluminium chloride was obtained from the dialysate.

Another public analyst testified that aluminium hydrate was readily soluble in the gastric juice, aluminium being readily extracted by a solution of hydrochloric acid of half the strength of normal gastric juice from loaves of bread made with this baking powder.

Professor Dunstan, of St. Thomas's Hospital, testified that aluminium hydrate, baked at a higher temperature than that of the interior of a loaf, was soluble not only in weak hydrochloric acid and in a dog's gastric juice diluted to a strength similar to that of human gastric juice, but also in a weak solution of sodium carbonate of the strength of intestinal juice. He had detected aluminium in the urine of a man fed upon bread made with this baking powder.

Several witnesses testified for the appellant that, in their opinions, aluminium hydrate was insoluble, that injurious effects would not be produced by the use of the powder in food, and that they were not aware of any bad effect having been traced to the use of baking powder containing alum.

The hearing of the expert testimony occupied five days, and the court dismissed the appeal with costs, affirming the conviction of the lower court.

In this connection the experiments may be recalled that were made by Paul Siem on the action of the aluminium salts administered subcutaneously in animals. No symptoms were caused for three or four days; then the animal suffered from loss of appetite, obstinate constipation, emaciation, languor, and disinclination to move. Next there were vomiting and loss of sensibility. When the animal was forced to move, the leg was raised, but trembled and twitched violently and was with difficulty placed on the ground. Sometimes there was general tremor or convulsive twitching, and sometimes extreme weakness or partial paralysis of the posterior extremities. The power of moving the tongue and of swallowing was completely lost, and the symptoms resembled those of acute bulbar paralysis in man. As the ætiology of this disease is often obscure, it might be well to consider the possibility of chronic alum poisoning.

Plumbism occurring in Steel Manufacturers.—Mr. Fray Ormrod, L. R. C. S., reports in the *British Medical Journal* for June 17th that certain manganiferous ores used in the manufacture of "Spiegeleisen," one of the ingredients used in the Bessemer process, contain several minerals, one of which is lead. A considerable quantity of lead escapes by the slag hole, some also coming out with the "Spiegeleisen" at the time of casting. In the latter instance, where the surface of molten metal is extensive, dense yellowish-white fumes are given off; these fumes have been found by analysis to contain from 64.5 to 74.5 per cent. of lead oxide. The men employed at the front of the furnace are exposed to these fumes for variable periods;

those at the slag hole are exposed for almost the entire eight hours' shift; while those at the pig beds are only exposed at the time of casting, once every four or five hours. The inhalation of these fumes produces sudden and severe symptoms of lead poisoning. This form of plumbism differs from others in that the lead enters the system as a vapor, either of volatilized metal or oxide finely enough divided to appear as smoke; the melting point of iron, at least 1,000° above that of lead, volatilizing the latter and the air oxidizing it. Colic, anæmia, and emaciation are the most frequent disorders in the men exposed to the lead fumes; and, with the exception of a fatal case of peripheral neuritis, no local or general paralysis has occurred, though for months at a time the men's systems have been under the influence of lead, some men having been laid up for a fortnight at a time at least a dozen times in two years.

Infant Mortality in Liverpool.—Dr. H. R. Jones and Mr. Herbert F. Davies read a paper on the excessive infant mortality in Liverpool, its causes and prevention, at a recent meeting of the Literary and Philosophical Society. An abstract of the paper, in the *British Medical Journal* for March 25th, states that by "infants" children under one year of age are meant. While the infant mortality for the whole of England for the ten years 1881 to 1890 was 142 per 1,000 births, the rate in Liverpool during the same period was 188, being an excess of 41 deaths per 1,000 births. The average number of children born annually in Liverpool exceeded 19,000, so that more than 7,700 infants died in those ten years who would have lived if they had enjoyed the average chance of life that prevailed throughout England and Wales. As to the causes of the excessive infant mortality in Liverpool, that from zymotic diseases might be ascribed to the density of the population; that from lung diseases to overcrowding and its attendant insanitary conditions; that from diarrhœa, atrophy, debility, and privation, to ignorance and neglect; while the excess from violence explained itself. Liverpool was notoriously the most overcrowded city in England, the population numbering 99 to the acre, or 115 if the docks were included. Of every 1,000 children born in Liverpool, 9 died during infancy by violent means, whereas the rate for all England was only 3. The conclusion could not be avoided that the great source of this criminal violence was drink, Liverpool having more drunkenness than any other English city.

The Vital Statistics of Russia.—The *British Medical Journal* for July 15th publishes a review of the annual report upon the health of the Russian Empire during the year 1890. The total population in 1890 was estimated at 116,652,610; the birth-rate was 46.1, and the death-rate 33.5 in a 1,000. These figures show a marked falling off in the natural growth of the population; in 1887 the birth-rate was 15, in 1888 it was 16.6, and in 1889 it was 14.3 in a 1,000. These figures are approximate only, no general census having been taken since 1857; the population in subsequent years being obtained by a calculation based upon the preponderance of births over deaths. The death-rate in European Russia in 1890 was 34.2, in 1889 was 33.4, in 1888 was 31.4, and in 1887 was 31.8 in a 1,000. The increase in the death-rate in 1890 is attributed to the greater prevalence of typhoid fever, whooping-cough, measles, phthisis, dysentery, cholera nostras, gastro-intestinal catarrh, and epidemic influenza. The diminished prevalence of small-pox may be attributed to the increased and voluntary practice of vaccination, about sixty-three per cent. of the children born during the three years ending 1890 being vaccinated. Leprosy would appear to be slightly on the increase; in 1888 there were 664 cases; in 1889, 792 cases; and in 1890, 839 cases of that disease reported. Venereal diseases appear to prevail to a disastrous extent in many parts of the country, being most prevalent in

the Caucasus and the governments of the south and east. Hundreds and even thousands of farm laborers flock to these districts at the time of the harvest, and their conditions of life are such as to allow of unchecked and wholesale promiscuous intercourse. Returning to their homes, the peasants carry with them any disease that they may have thus contracted; in this way venereal diseases are widely disseminated throughout the country, each case becoming a fresh center of infection, both by ordinary and by sexual intercourse. One instance is mentioned in which a peasant thus infected in the course of four months no fewer than twenty-three persons. The sanitary condition of inhabited localities is far from satisfactory, only Odessa, Warsaw, and Yalta having sewerage systems. The water supply is very generally condemned, only forty-six out of eighty-six towns that are the centers of governments possessing water works; of these, nine distributed water of impure quality, and in twenty-two both the water-works supply and the water obtained from other sources were of bad quality.

The Birth and Death Rate in Europe.—The *British Medical Journal* for August 5th publishes an abstract of a paper by M. Langlois in the *Annales d'hygiène publique et de médecine légale* that gives some highly interesting figures: "Everywhere in Europe there is a continuous and gradual diminution in the number of births. Thus, in England in 1879, there were 34.7 births for each 1,000 inhabitants; but in 1890 the figures were 30.2 births for each 1,000 inhabitants, after having been successively 33.9 (1881), 32.5 (1885), 30.6 (1888). In Belgium in 1879 the number of births were 31.5 for each 1,000 inhabitants; in 1890 the births were but 28.7. In the German Empire in 1879 the number of births to each 1,000 inhabitants was 38.9; in 1890 this proportion had fallen to 36.7. In Prussia proper the proportion in 1879 was 39.2; it was but 36.6 in 1890. Thus throughout Europe there has been an increasing diminution in the number of children born. In France, however, this decrease is more marked than in other countries, because the proportion of births is lower than elsewhere. In 1879 there were 25 children born for each 1,000 inhabitants; in 1890 the proportion was but 21.8, or a diminution of nearly one sixth. Yet, to form a just estimate of the effect of this decrease of births on each country, we must take into account the mortality of the country. The nations of Europe, for this purpose, may be divided into three groups; those of the south: Spain, Austria, Italy, even Germany, in which countries the number of deaths in 1890 varied from 32 to 25 for each 1,000 inhabitants; those of the center: France, Belgium, Switzerland, of which the respective proportions were 22.01, 20.21, 20.82, for each 1,000 inhabitants. Finally, the people of the north: England, Denmark, Sweden, Norway, where the respective proportions of deaths were 19.01, 17.19, 16.84, 16.14, for each 1,000 inhabitants. Thus it will be observed that while France has fewer births than any other country of Europe, in regard to mortality she occupies an intermediate position. The south of Europe, contrary to general opinion, has a much higher mortality than the north, especially for children, of which the mortality comprises a considerable proportion of the number of deaths in each country. The mortality of children in France is frightful, although there is no increase, but rather a diminution, in the number of infants which die during their first year. If from 1806 to 1809 22 per cent. of the newborn children died, the percentage in 1860 was but 17.63, and it fell to 15.76 in 1888, to 14.82 in 1889, while in 1890, a year of epidemic which did not spare children, the percentage was 16.77. We have to admit that out of 1,000 children born in France, 167 die in their first year; and this number is altogether too large, notwithstanding that Bavaria loses 312 in every 1,000, Italy 212, Switzerland 190, Belgium 174. The public hygiene of a country which, out of 800,000 born, loses

167,000 in their first year, is manifestly inefficient, although enormous progress has been made in the last ten years."

The Isolation of Infectious Diseases in London.—The *British Medical Journal* for June 17th, states that at a recent meeting of the Metropolitan Asylums Board it was stated that on an average only fifty per cent. of the fever and diphtheria cases requiring admission to the manager's hospital could be dealt with. At Deptford recently, where scarlet fever was prevalent, there were patients that ought to be removed from their residences, but absolutely no place to remove them to. As the board had failed to provide the accommodation that it has educated the public to expect, patients must either be left in their own homes, with a fair probability of spreading the epidemic more widely, or at a moment's notice temporary isolation hospitals must be improvised all over London, with scratch staffs of doctors, nurses, and attendants, all of whom would be scattered to the four winds so soon as the epidemic subsided. The difficulty is not lessened by the fact that, even to make such provision, the authorities would have to run the gantlet of injunctions and local opposition to their hospitals. These problems are confronting health boards throughout the United States, and apparently the sooner the question is grappled with and settled, the better for all concerned.

School Quarantine.—The *Medical Week* for July 28th states that Dr. Ollivier has read a report on this subject which may be summarized as follows:

In a communication to the Academy in May last, Dr. Gréard insisted on the necessity of introducing certain modifications in the regulations in force at the present time in schools and colleges on the duration of the period of isolation for infectious disease.

Dr. Gréard's letter was referred to the Section of Public Health and Forensic Medicine. After giving the matter the most careful consideration, the section is now in a position to formulate the following conclusions:

A.—(1) Children affected with small-pox, scarlatina, varioloid, and diphtheria should stay away from school for forty days from the date of the first appearance of the disease—i. e., from the commencement of the period of invasion.

(2) The period of quarantine need not exceed sixteen days in the case of measles and variella.

(3) In respect of whooping-cough, isolation should be continued for three weeks after the disappearance of the characteristic cough.

(4) In the same way in mumps it should be continued for ten days after all local manifestations have subsided.

B.—(1) The patients should be submitted to the following measures of disinfection before they are allowed to return to school:

Douching of the nasal, buccal, and pharyngeal cavities with antiseptic solutions.

General scrubbing with soap and water, the hair inclusive. Thorough disinfection by steam under pressure of the clothes the patient was wearing when he was taken ill.

(2) In accordance with the regulations at present in force:

(a) The room occupied by the patient should be thoroughly ventilated. The walls and articles of furniture should be disinfected with a 1-to-1,000 solution of corrosive sublimate. The curtains, bedding, and mattress should be sent to the steam stove.

(b) Patients contracting one of the infectious diseases above enumerated outside a public educational establishment can not be readmitted unless they produce a medical certificate to the effect that the above-mentioned measures of disinfection have been carried out, and specifying the exact nature of the affection as well as the duration of the period of isolation.

The Preservation of the Hymen from a Medico-legal Point of View.—While no well-informed physician would for a moment believe that the absence, or the existence of vestigial remains, of the hymen was good evidence that a woman was not a *virgo intacta*, there are reported cases in which the existence of a hymen has interfered with the delivery of a pregnant woman.

The *Medical Week* for July 14th gives the report of a recent meeting of the Paris Medico-legal Society, at which Dr. Motet reported an interesting medico-legal case in which the plaintiff, a woman whose first husband had died after eighteen months of married life, married a second time; after cohabiting eight months with her second husband she brought an action for divorce on the ground that her husband refused to fulfill the obligations of matrimony. She was submitted to a medical examination, when it was found that her hymen was still intact. The court held that the medical evidence was very much weakened by the fact that the plaintiff had already been married once, and that there was no evidence whatever of voluntary abstention on the part of the husband. Dr. de Beauvais stated that he had seen a case of pregnancy with unruptured hymen in a domestic servant who had been raped by her employer. She had consulted a medical man immediately after the act, but from the presence of the hymen the latter had regarded her as a *virgo intacta*. Dr. Vibert advised that in a medico-legal examination one should take into consideration not only the state of preservation of the hymen, but also any inherent peculiarity that might be present, such as a resistant nature of the hymen. Dr. Guillot very properly called attention to the fact that rape does not consist so much in the destruction of the hymen as in the more or less complete carnal knowledge of a woman without her consent. This is so for the case that under the law a prostitute may bring an action for rape. Dr. Christian said that in a case similar to that referred to by Dr. de Beauvais, the physician, before concluding that the girl had not been raped, should examine her for ecchymoses, traces of seminal fluid, etc. Dr. Motet also reported a case of a girl of sixteen who had been arrested in the street and sent to the venerable wards of the Lyons Hôtel Dieu for treatment for venereal disease. While she was there it was discovered that she was in an advanced state of pregnancy, although her hymen was intact and the orifice of the vagina barely admitted the little finger. The girl stated that she had been raped a few months previously.

New Inventions, etc.

A CANNULATED SURGICAL NEEDLE.

By W. T. HAMILTON, M. D.,
IRONATON, ALA.

I HAVE, with the assistance of Messrs. Tiemann & Co., of New York, got up a new cannulated surgical needle which answers admirably the purposes of every-day surgical practice. It is in truth a modification of the Crofford needle, with the eye in the point like a ligature or artery needle; it permits the use of the ordinary silk suture thread or catgut, with which a very pretty loop suture can be made, while the cannulated feature of the instrument adds fourfold to its value, as it makes practically two instruments in one. With it the silver hare-lip

pin, lead, silver, or britanna wire is used, either with or without the figure-of-eight twist of the thread, as the case may demand. This feature will be found particularly suitable in scalp and wounds of the face. I have used the instrument repeatedly

of late and found it to answer all drafts made upon its convenience and utility. It is made by Messrs. Tiemann & Co. in two sizes—one for heavy work, so to speak, such as abdominal surgery, ruptured perineum, etc.; the other smaller, lighter, and more adapted to general service. The woodcut illustrates the instrument.

Miscellany.

The Postponement of the International Medical Congress.—In a leading article the *Lancet* says:

"This change in what the profession throughout the world has regarded as a 'fixture' has come upon it as a considerable surprise. Indeed, nowhere more than in Italy does it seem to have been less anticipated, for, up to the eleventh hour, the organizing committee was intimating from its seat in Rome its acceptance of 'adesioni' from representative physicians, surgeons, and sanitary officers all the world over—'adesioni' or pledges given on the expressed or implied understanding that the congress was to meet on September 24th. From the same central authority, moreover, till quite recently, arrangements were announced enlarging the scope and the *personnel* of the gathering, such modifications in the original programme being possible or practicable only on the assumption that the autumn and not the spring was to be the season of rendezvous. Not only the congress, but its hardly less important accompaniment, the International Exhibition of Hygiene, was so far advanced toward completion that the time for receiving exhibits was officially declared to be closed, while the disposition and allocation of such as had already come to hand—many of them, be it noted, of a quality which, if not perishable, does not improve on keeping—were already in progress. Now, like a 'bolt from the blue,' all these preparations or finishing touches are arrested and the 'triennial parliament of the healing art,' as it was designated in these columns, is so far a misnomer that its next meeting will not take place till well into the 'quadriennium'—the Easter of 1894.

"This is much to be regretted on many grounds. As already demonstrated, 'præconis ad fastidium,' the last week of September was the one period of the twelvemonth which—the climate of Rome being considered in conjunction with the business engagements of practitioners and teachers alike—was that most free from objection as the meeting time of the congress. It was the date fixed by a common consent, which was arrived at after much correspondence and exchange of views between the leading centers of practice and education in both hemispheres. It was the date, moreover, at which the capacity of Roman hotels and *pensions* is put to the least strain by the tourist or traveling world—the date at which the congress could have held its sittings undisturbed and undistracted by the pressure of such non-professional interests as (at Easter, for example) are at their height in the Eternal City. It was the date when, as the Romans themselves say, according to 'una sperienza secolare'—the tradition of centuries—the climate is most equable and the weather delightful, and when the 'congressisti,' having appropriately wound up their autumnal holiday by just a taste of Rome's intoxicating 'Ottobrate,' would return to their duties in the professional chair, the biological laboratory, the clinical ward, or the private sick-room, refreshed and sustained for

the close of one working year and the opening of another. *Dis aliter visum.*

"There is no doubt that the grounds on which Dr. Baccelli and his fellow committeemen have postponed the congress are more than sufficient to justify the step. The stealthy, insidious approaches of the Asiatic scourge, at first so insignificant as well-nigh to lull suspicion, are now transformed into something like a 'reconnaissance in force,' to use the military phrase, portending, if not actually announcing, a 'general advance.' From official, and still more from non-official, sources, particularly in France and Russia, the organizing committee in Rome have received intelligence which would make further inaction culpable; intelligence that cholera has in these countries, if not in others assumed an epidemic form, demanding the presence at the various infective foci of all the medical surveillance that can be brought to bear, and making even temporary non-attendance at the scene as unprofessional as it would be blameworthy. Italy herself, it is safe to assume, is even more gravely affected by the advancing enemy than her official intimations would let the outside world believe—at any rate she is suspending movements and gatherings customary at this season to an extent not quite consistent with such sanitary reports as appear in her public press. The grand manoeuvres of her army, there is now no longer any doubt, will be suspended for the autumn or until such time as the epidemic is in full retreat. If a partial exception to this *mot d'ordre* of the 'Ministero della Guerra' be made, it will include (so we are on high authority assured) only such army corps as have registered no case of the disease, and even in these the manoeuvres will be limited to what are called 'manovre di compagnia.' In spite of official or semi-official contradictions, we are also in a position to state that the conscription, already begun in central Italy, has been suspended in more than one quarter of the Alta Italia, where, as our columns have already shown, there have been many cases of cholera, more than half of which have proved fatal. On the other hand, with an activity in significant contrast to the inaction of the land forces, the Italian navy will carry out its customary evolutions on the high seas—this year in Neapolitan waters.

"So at whatever inconvenience to transatlantic or colonial 'congressisti'—an inconvenience, however, which could not but be less than that imposed by quarantine on their return from a cholera-stricken country—the medical world must bow to the *force majeure* of sanitary conditions and resign itself to meeting in congress at the far less desirable season of April, 1894. Not that there are no compensations for this untoward change of programme. The meeting of September 24th would, it is an open secret, have overtaxed the resources of the Eternal City, rehabilitated though it has been under no auspices more energetic than those of Dr. Baccelli. For one thing, the influx of intending participants at the gathering so far exceeded all calculation as to be likely to put to a severe test the capabilities of even larger and richer communities than that of Rome. It was, no doubt, in compliance with the most hospitable instincts, but at the same time equivalent to a courting of confusion or worse, that the medical students of Italy—if not those of other countries—should have been admitted to a gratuitous participation in the proceedings. When the number of what we may call legitimate members reached the formidable total of some nine thousand it was surely a stretch of good nature to add to the inevitable overcrowding by the free admission of half as many more undergraduates, whose appreciation of the discussions could at best have been imperfect. Another consideration is that the unprepared condition of the Policlinico—the edifice in which Dr. Baccelli hopes to inaugurate the rehabilitation of Italian medicine—is such that only a limited part of it would have been available for the vast assemblage invited to meet in it next September. We are informed that a special grant has been set apart by the State for the urgent completion of the as yet but partially constructed building; but, from what we can gather, all the energy in the world, backed up by more than half the means the Italian Treasury can afford, would scarcely suffice to put it next Easter in a condition to accommodate so many thousands. The suggestion—not made lightly—that the grand structures of imperial Rome—grand even in their ruin—the Colosseum, for example, or the baths of Caracalla or Diocletian, temporarily fitted up for the biggest medical congress the world has yet seen, might solve the difficulty of

accommodation most satisfactorily. They have been used—the baths of Caracalla particularly—for similar purposes already and might be so employed again. The awning that in the heyday of the Colosseum was spread over the vast arena by the marines of the Roman navy to protect the spectators from sun or rain is a resource which might once more be made available for the meeting of 1894. The temporary woodwork that, in 1869-'70, converted a transept of St. Peter's into a sufficient chamber for the multitudinous Ecumenical Council is a device that could well be applied to either of the commodious and many-chambered baths above referred to. In any case the six months gained by postponement will give the organizing committee time to adjust its preparations to requirements only realized at the eleventh hour, and to mitigate its own disappointment as well as that of its guests at a sudden change of programme to a season less happily chosen than that originally selected."

Salol as an Intestinal Antiseptic.—Dr. E. Mansel Symptom contributes the following to the August number of the *Practitioner*: "The action of salol in the human body is now well known and is briefly as follows: After having been swallowed and passed through the stomach unchanged, it is split up in the duodenum by the pancreatic juice into its constituents—salicylic acid and carbolic acid. Their action will be alluded to more in detail later on, but it may here be said that they are thrown out of the body partly by the kidneys (the urine not infrequently being blackened by the carbolic acid) and partly by the intestinal tract in the faeces. And from experiments on dogs whose pancreases have been extirpated, there seems to be reason to think that salol can be absorbed from the intestine without the intervention of the pancreatic juice. As to its action on digestion there are different opinions; some authorities say that it unsettles the digestive processes and that it actually sets up gastric trouble. These statements refer to its action in typhoid fever, which will be mentioned presently; other observers have, however, noted directly the contrary results. I have personally taken salol in five-grain doses three or four times a day, both before and after meals, when I have been perfectly well, without experiencing the slightest interference with digestion or appetite. The following experiments will show, however, that salol does appreciably affect the different digestive ferments so far as regards their rate of action:

"*Experiment I.*—Ten grains of arrowroot were boiled in two ounces of distilled water, cooled down to 100° F., and ten minims of Bleasdale's pancreatic essence added. The solution became perfectly clear. When one grain of salol was added before boiling, the starch required twice the amount of pancreatic essence, and an hour's more time (being kept at the same temperature) before the conversion was complete. If the salol was merely added with the essence it made no difference. The same results followed, only less marked, from the use of half a grain of salol.

"*Experiment II.*—Five grains of boiled and finely chopped-up white of egg were pounded up with the following mixture: Bengel's liquor pepticus, twenty minims; dilute hydrochloric acid, ten minims; and two ounces of distilled water. For four hours this mixture was kept at a temperature of 100° F. The albumin had entirely disappeared and the mixture gave evidence of containing peptones. The addition of half a grain of salol checked the process considerably; at the end of the same time there were several fragments of egg undissolved, and two or more hours were required for complete dissolution. Both these sets of experiments were frequently repeated and the results were distinct and constant."

"Before finishing this brief account of salol, it may be said that it has been accused of producing herpes and of increasing the delirium which frequently occurs in the course of typhoid fever. I have not noticed this latter myself either in that complaint or when I have used salol in cystitis.

"In normal digestion the semi-digested acid chyme is poured out from the pylorus into the small intestine, to be exposed to the influ-

* Similar experiments made with salicylate of sodium showed that this drug had no action in pancreatic digestion, but about the same as salol in peptic digestion.

ence of the bile and pancreatic juice. These complete the digestion of the various food stuffs, and some of the products of this digestion are due to the micro-organisms which are present in the intestine. Their work seems to be modified or kept in check by the presence of bile, for, as Foster remarks, 'Bile possesses some antiseptic qualities. Out of the body its presence hinders various putrefactive processes; and when it is prevented from flowing into the alimentary canal the contents of the intestine undergo changes different from those which take place under normal conditions and leading to the appearance of various products, especially of ill-smelling gases.'*

'The stomach undoubtedly is responsible for some cases of dyspepsia, where the chyme is passed on to the intestines in an imperfectly prepared manner, which produces duodenal disorder. But in the following class of cases we have, I think, evidence that occasionally the secretions poured into the intestine are at fault. The patient is probably of a 'bilious' temperament, he may have a clean tongue with great loss of appetite and consequent loss of flesh; no pain during a meal, but coming on about two and a half to three hours after. Very likely he is constipated and when his bowels are relaxed the motion is grayish white. 'As a rule, he will not suffer from nausea, only a little retching sometimes, and instead of the gas being acid, as it so often is, it may be quite alkaline and 'soapy,' as a patient once told me. The seat of pain is the lower part of the abdomen and is relieved by passing wind. There will perhaps be a slight yellowness, hardly amounting to actual jaundice. These cases belong, I believe, to the same class as those described by Dr. Allchin in his lectures on duodenal indigestion. I also believe that the symptoms are due to excessive and faulty fermentation in the small intestine, owing to alteration in character and amount of the ordinary digestive fluids and more particularly of the bile. I have given dilute nitrohydrochloric acid to the patients, sometimes combined with liquor pepticus, to help the stomach to do its work properly; but it has made little or no difference in their condition. And opium in any form by the mouth has not given that speedy relief which it does in gastric affections. So, latterly, I have been in the habit of beginning with four or five grains of calomel, and following it in an hour or two's time with ten-grain doses of salol every four hours. This, to use the language of a somewhat enthusiastic patient, 'acts like a charm' when taken about an hour and a half after meals. The pain ceases, the swelling of the abdomen does not appear, the appetite improves, and, more important still, the wasting (due, I presume, to the non-digestion of a large part of the food) departs.

'Another complaint wherein I have found salol exceedingly useful is a form of infective diarrhoea. Some months back I saw a family in a village near Lincoln who all had diarrhoea, passing dark-brown watery stools five, six, seven, or eight times in the twenty-four hours, attended with severe abdominal pain. In a few days several of the inhabitants of the village were seized with the same complaint, and every one had been into the first-mentioned house. Several more got it from the second source of infection. I regret that I was unable to discover any probable origin of the disease. I tried opium alone in some of the cases, but its action was far inferior to that of salol, whether combined with opiates or not.

'In cases of ordinary diarrhoea, too, there are few remedies which more speedily check the flow and the pain than ten-grain doses of salol. Some years ago, in the *Lancet*, I advocated giving glycerin of borax in the diarrhoea of infants, believing that undue fermentation in the intestines was the *fons et origo mali*. It does answer well, as I have over and over again seen; but I prefer in the severer cases to use salol in doses proportionate to age, as being a little more certain, more antiseptic, and almost as agreeable to take.

'Lastly, I have been using salol exclusively in typhoid fever, not so much on the idea of combating the specific poison, but of cleaning and keeping clean the intestinal tract, and so subduing the irritation of the glands of Peyer's patches and other ulcers there, and that caused by the secretion from these ulcers in the intestine. Salol also pre-

vents the excessive formation of wind, which is sometimes so vexatious a trouble to the patient. Salol brings the temperature down generally one or two degrees, causes abundant perspiration (this can be readily combated by giving oxide of zinc, tincture of belladonna, and some quinine in a mixture), reduces the number of stools from twelve or fourteen in the twenty-four hours to three or four, and, when they are offensive, deprives them of any odor whatever. No bad effects were noticed with regard to its action in producing delirium. Its use was continued in typhoid fever for about a week after the disappearance of diarrhoea. It was always given in ten-grain doses suspended by means of compound tragacanth powder, at first (in typhoid fever and other complaints) every four hours, then every six, and for the last week three times a day. It was always given after food.'

A Proposed Milligrade Thermometer.—In the July number of the *Indian Medical Record*, published in Calcutta, there is an interesting article On the Milligrade Thermometer of Galileo, by Dr. R. Temple Wright, surgeon and lieutenant colonel in the Indian Medical Service, in which he says:

'The centigrade scale is now used in all countries for scientific purposes, and all chemical and physical text-books give the formulae for converting the readings on Fahrenheit's scale and Réaumur's scale into centigrade, and *vice versa*.

'But this is a troublesome process, so comparative tables are published, in which one can see the various readings at a glance, but they usually go no higher than the boiling point of water and no lower than the freezing point of mercury.

'These are utterly useless for the extremes of heat and cold just mentioned, so I have constructed tables of comparative temperatures, ranging from +1,000° F. to -1,000° F., by which one can see at a glance the readings in these three scales and in a fourth. That other I call the milligrade scale, and I dedicate it to the memory of the illustrious Galileo, whose tercentenary was celebrated the other day, the father of modern science, for which he became a martyr, losing his liberty, and very nearly losing his life.

'The following notes show that he was the first to apprehend the scientific principle of thermometry, and, as he made his degrees represent thousandths of the volume of the bulb, I would propose now that we should accept his suggestion and divide each degree of the centigrade scale into ten parts, thus having 1,000 degrees between the freezing point of water and its boiling point.

'The centigrade degrees are so large that we frequently are obliged to use fractions for recording observations, and it is only the convenience of using whole numbers that has made the clumsy scale of Fahrenheit so popular.

'International jealousy would probably prevent countries which have adopted Fahrenheit's scale and Réaumur's scale from bringing the centigrade scale into common use, but our common veneration for Galileo ought to make all nations willing to adopt the milligrade scale, which can be equally convenient, both for science and for common use.

'We already have a precedent in the barometer, for on the continent of Europe the height of the mercury is expressed in millimetres, and in graduating thermometers the boiling point of water is noted at a barometric pressure of 760 millimetres.'

'The supporters of binary subdivision commonly object to the decimal system of notation on account of its fractions, and though this trouble may occur in the centigrade scale, the difficulty almost disappears in using the milligrade scale, in which it becomes easy to combine, in a practical way, the advantages of both decimal and binary subdivision with the volumetric system.

'Thus, if the whole be 1,000 on the scale,

then half,	or $\frac{1}{2}$,	will be 500,
" a quarter,	" $\frac{1}{4}$,	" 250,
" an eighth,	" $\frac{1}{8}$,	" 125,
" a sixteenth,	" $\frac{1}{16}$,	" 62.5,

and even the last is by no means a troublesome fraction.

'To obtain the full advantage of the milligrade thermometer, we must take for zero the freezing point of water, as in the centigrade scale,

* Foster's *Physiology*, 1889, p. 426. Also see a very interesting paper by Professor C. S. Sherrington, The Escape of Bacteria with the Secretions, *Journal of Pathology and Bacteriology*, February, 1893.

which would seem to be the natural starting point for measuring heat, not the freezing point of mercury, as Fahrenheit did, for the annexed tables show at a glance that this clumsiness must cause many temperatures which frequently occur to be noted in most awkward fractions. With this proviso it becomes quite easy to express and to remember temperatures on the milligrade scale—*e. g.*, we say 'It is freezing,' when we register $+32^{\circ}\text{F.}$, or $+0$ on the centigrade and milligrade scales.

"It is very cold, it is nine degrees below freezing,' when we write it $+23^{\circ}\text{F.}$, or -8°C. , or -50°M.

"The air is temperate,' we write 50° to 59°F. ; or 10° to 15°C. ; and 100° to 150°M.

"It is warm,' we write 68° to 77°F. ; or 20° to 25°C. ; and 200° to 250°M.

"It is a very hot day,' we write 86° to 95°F. ; or 30° to 35°C. ; or 300° to 350°M.

"A hot bath' might be 104°F. , or 40°C. , or 400°M.

The following temperatures may occur in various illnesses, say between 95° and 110°F. , and it will be seen at a glance that while the Fahrenheit and centigrade scales must often express the intermediate readings in fractions, the milligrade can almost always employ whole numbers for its records.

Temperatures in Illness.

" Fahrenheit.	Centigrade.	Milligrade.
95-0°	35°	350°
96-8	36	360
98-6	37	370
100-4	38	380
102-2	39	390
104-0	40	400
106-8	41	410
107-6	42	420
109-4	43	430

"So, since there is to be an international medical congress at Rome in September, 1893, might we not venture to present these tables to the medical men there assembled, and invite them to consider the advisability of adopting the milligrade scale originally recommended for a thermometer by Galileo, the great Italian philosopher?"

Ureteritis Membranacea.—Professor von Jaksch (*Ztschr. f. klin. Med.*, xxii, 6) records a case characterized by the passage in the urine of formed casts, composed of fibrin and mucin, very similar to those described by Leyden and Curschmann from the bronchi, and by Nothnagel and others in the feces in so-called colica mucosa. The patient, a woman of forty-five, was admitted into von Jaksch's clinic over two years ago. Seven years previously she began to suffer from pain in the back and region of the right kidney, after the cessation of which, pain set in the left loin. This continued for a long time, sometimes with vomiting. Two years later a small calculus was passed with severe left renal colic. Some relief followed; but attacks of colic, vomit, muddy urine, and painful micturition occurred at intervals, accompanied occasionally by rigors and fever. Examination of the patient showed all the systems normal, except the urinary, and there was no tumor or swelling in the abdomen. The urine, with a neutral reaction, contained some albumin and showed a dull whitish sediment, which consisted of ribbon-like structures about ten centimetres long, translucent, spirally arranged, and unbranched. They varied little in breadth and resembled very closely to the naked eye the appearance met with in the sputum and feces, and this resemblance was carried further in that they consisted chemically of mucin and fibrin. Microscopically, they were like Curschmann's spirals without the central thread. On the surface were seen flattened epithelium, singly and in groups, such as is found in the bladder and ureter, amorphous masses, and crystals of sulphate of calcium. Throughout the sediment were scattered amorphous masses composed of carbonate of calcium, very fine crystals of triple phosphate, well-formed sulphate-of-calcium crystals, and epithelium from the ureter and bladder. Neither cells from the renal tubes nor leucocytes were to be found. With rest in bed the pain in the renal region disappeared and the condition of the urine changed in a few

days, the spiral formations ceasing and the crystalline forms becoming less. Sulphuric-acid lemonade was administered, and under its use the urine became acid, and the patient was discharged in a few days much improved. According to the history and the appearances observed in hospital, the case was one of renal calculus. The ribbon-like structures, from their length and breadth, the unbranched condition, and the form of the epithelium, evidently originated in the ureters and probably depended upon the state of lithiasis. Von Jaksch remarks that these forms give one the impression that all mucous membranes might produce them under certain conditions. Above all, certain chronic states of irritation of the mucous membrane favor their origin. They are found in the alkaline sputum and alkaline feces, and in the urine so long as it reacted neutral or weakly alkaline. Therefore an alkaline state of the secretions appears necessary, and it is supported by the rapid disappearance of the structures on the urine becoming acid. Von Jaksch proposes for the affection the name of ureteritis membranacea.—*Practitioner.*

To Contributors and Correspondents.—The attention of all who purpose favoring us with communications is respectfully called to the following:

Authors of articles intended for publication under the head of "original contributions" are respectfully informed that, in accepting such articles, we always do so with the understanding that the following conditions are to be observed: (1) when a manuscript is sent to this journal, a similar manuscript or any abstract thereof must not be or have been sent to any other periodical, unless we are specially notified of the fact at the time the article is sent to us; (2) accepted articles are subject to the customary rules of editorial revision, and will be published as promptly as our other engagements will admit of—we can not engage to publish an article in any specified issue; (3) any conditions which an author wishes complied with must be distinctly stated in a communication accompanying the manuscript, and no new conditions can be considered after the manuscript has been put into the type-setters' hands. We are often constrained to decline articles which, although they may be creditable to their authors, are not suitable for publication in this journal, either because they are too long, or are loaded with tabular matter or prolix histories of cases, or deal with subjects of little interest to the medical profession at large. We can not enter into any correspondence concerning our reasons for declining an article.

All letters, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication. No attention will be paid to anonymous communications. Hereafter, correspondents asking for information that we are capable of giving, and that can properly be given in this journal, will be answered by number, a private communication being previously sent to each correspondent informing him under what number the answer to his note is to be looked for. All communications not intended for publication under the author's name are treated as strictly confidential. We can not give advice to laymen as to particular cases or recommend individual practitioners.

Secretaries of medical societies will confer a favor by keeping us informed of the dates of their societies' regular meetings. Brief notifications of matters that are expected to come up at particular meetings will be inserted when they are received in time.

Newspapers and other publications containing matter which the person sending them desires to bring to our notice should be marked. Members of the profession who send us information of matters of interest to our readers will be considered as doing them and us a favor, and, if the space at our command admits of it, we shall take pleasure in inserting the substance of such communications.

All communications intended for the editor should be addressed to him in care of the publishers.

All communications relating to the business of the journal should be addressed to the publishers.

Contributors who wish to order REPRINTS of their articles should do so on a blank prepared for that purpose, which will be sent to them by the publishers on receipt of a request to that effect. The order should be sent to the publishers, and not to the editor.

Original Communications.
